

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

PLATE I.

MR. WILLIAM SMITH, OF WOOLSTON. AN AUTOBIOGRAPHY.

At the death of my father in 1837 I came in possession of my farm, now known as the Woolston Farm, and thus stood the representative of the family who had possessed it for 200 years. It consisted of eighty-six acres of grass land and five acres of ploughed land upon the flat, near the house; and on the clay hill, one-and-a-half miles from home, there was a grass field containing nine acres, and four fields of what was called ploughed land, containing together thirty-eight acres; yet in each of these fields there were two acres of roundabouts or waste land, most of which was said to be worthless for cultivation. In all 136 acres. The ploughed land was worked upon the four-course system, viz., first year dead fallow, then followed wheat, and after that beans, and last of all came wheat again. Barley or oats came as the last crop occasionally. Four good horses were always kept to work this thirty-five acres of arable land, and very frequently there were five kept to do it with the work of the whole farm. I at once ploughed-up the eight acres of roundabouts or idle land in the four ploughed fields, and thus increased my ploughed land to forty-three acres.

In 1842 I bought a ploughed field containing thirteen acres adjoining my land upon the flat near home. Soon after this I ploughed-up fields now known as Nos. 1, 3 part 2, 4, and 5, containing together forty-two acres, and thus increased my ploughed land to ninety-eight acres; and soon after this I bought another field of grass land near to my flat land. I at once ploughed it up and thus increased my arable land to 113 acres. To work it, it needed six good horses; and to save the carting of the heavy land corn and manure one-and-a-half miles, I built a barn and yard upon it.

In 1845—after having worked my heavy land upon the dead fallow and three-crop system, and finding that the crops were not over productive, about 20 bushels per acre, fallow land included—I came to the conclusion that subsoiling must be good upon such land, so I had a subsoiler made, and tried the first time on field No. 2, heavy land, by ploughing the field across to make sure that the trial should be fair. I subsoiled a piece across the middle, leaving the top and bottom of the field unsubsoiled. The land had been manured alike. In the February following I planted the field with beans: they all came up well together; but in May it could be seen that those on the unsubsoiled land were taking the lead, and by the end of May they were fully eight inches the highest, and they kept the lead up to harvest, when it could be plainly seen that they were not only the highest but the fullest of corn. This convinced me that deeper culture was needed for

beans, but with only six horses I could not find time before Christmas to plough and subsoil in the ordinary way, a field of land a year for beans, for the plough needed four horses to work it, and the subsoiler needed three—seven good horses in all; therefore, as I had only six, I was obliged to make any shift to do a bit at all. I did not like it, so I contrived the plan of ploughing my land in ridge, a yard from ridge to ridge; and then, subsoiling round the ridges in this way, I could ridge first and then subsoil half-an-acre a-day with four horses. The work was heavy to the man as he had to hold the plough sideways all the time. In the February following the land was planted with beans, one row on each side the ridge. They thrived well, and I had a good crop. After harvest I took my subsoiler and pulled it with four horses along every ridge and thus cracked the land, and then passed a powerful cultivator, worked with six horses, across the ridges, smashing the whole to a depth of six inches, and thus prepared my land for wheat the next year. I liked the plan and continued to work upon it till 1855, when I began to work with steam power. It had one drawback, viz., heavy work to the man.

In 1855 it occurred to me that if I combined a powerful double mould-board plough and two subsoilers together and worked it with a steam engine, I could throw up a ridge a yard in width and subsoil it at one operation, and I resolved to make a trial of it by setting my blacksmith to work to make a combined ridger and subsoiler; and I also had made a three-tined smasher upon the same principle, by merely substituting another subsoiler, or rather a powerful tine in the place of the double mould-board plough. I then provided myself with a windlass, &c., and a seven-horse power engine, and in December of that year, after selling-off three horses to make room for the engine, I made a start. The first day's trial showed many defects in my arrangement. The implements were right but the speed of the engine was wrong, for it was much too fast, for the implement when set to work at a depth of six inches held the engine with 50lb. pressure of steam upon it at a dead stand. We relieved the engine by taking the implement out of the ground two inches; at this depth (four inches) the engine made the implement trot across the field full five miles an hour. The lookers-on, who looked old and shook their heads when they saw the engine stuck fast, now laughed as they trotted along with the implement. Yet the depth (four inches) for ridging and subsoiling would not do for me. The turning of the implement at land's-end would not do with one rope in front to pull the implement along, and

the other hooked on behind to pull the back rope up; for as soon as the implement had been stopped we had to pull with the strength of three or four men to unhook the back rope, and at turning the first time we lifted the implement with levers to place it in position for going back. This done, and hooking on the rope, we trotted across the field again, but as soon as we stopped the second time I had the back rope unhooked and pulled on to the front of the implement, and hooked it to the stem of the front wheels with a strong S hook; and without the aid of any lifting and levers we set the engine to work to pull the implement round itself, which it did in first-rate style, and thus saved for ever after all the levering and pulling. Our anchorage was bad; they were wooden ones, needing holes dug in the ground (at the end of each bout), three feet wide and from two to three feet in depth, and as I had got a number of these holes prepared ready for the first day's trial, the lookers-on asked whether I had got a lot of graves dug ready to bury them. I could stand all that. Besides making use of these holes, I had to contrive, before I started, another anchor, for with the two that I had received as a set I could not start; therefore I fixed upon a stile-post for a third, fixing the snatch-block to it with a strong rope. As soon as the implement had crossed the field four times, I told the lookers-on that I had seen enough, but that if they would like to trot round again they might. They should, was the reply, and away they went some half-dozen times, and all was over for the day. I got new pulleys put upon the engine and windlass, to reduce the speed of the implement to about two miles an hour; a set of new anchors (iron ones)—those now known as the Woolston anchors; a fourth snatch-block; and a turning bow for the implement, to attach the ropes to, to enable the engine to turn it easily at land's end. As soon as I had got all this done I started again, and got off well, using the smasher, and completed two fields—No. 1 and No. 2 light land—containing together twenty-five acres, and we packed the tackle up till the March following, when we brought it again to work No. 8 heavy land over twice for peas (under horse culture it would have been dead fallow), and we got on well, for we smashed the twelve acres and crossed it by steam, and then scuffed it once by horses, and then burnt a lot of the twitch that we had dragged out, and then drilled in the peas. All this was done in ten days, and at harvest I had a good crop—5 qrs. per acre. We then packed up the tackle again, and after harvest we set to again, and the best thing that can be said about what I did then is to re-write what I wrote to the *Mark Lane Express*, on the 18th of November, 1856:

"I have since harvest ploughed by steam the whole of my farm, excepting a bit of wheat stubble left to try an experiment on in the spring, and a bit of clover ley ploughed with horses. It may be interesting to some of your readers to know the results. I find that the implements exhibited by me at Chelmsford are perfect; that any seven-horse engine is sufficiently powerful for every useful purpose; that any cold clay, hilly, and uneven field may be ploughed; that in ploughing my bean and pea stubbles, at a depth of six inches, I did an acre in one hour and thirteen minutes and an average of five acres per day, including time for shifting from field to field, at an average cost of 5s. 2d. per acre, including men, coal, water, and horses, for shifting; and that in ploughing my wheat stubbles at a depth of eight inches on the heavy and ten inches on the light land, I did an acre in two hours and an average of three acres per day, including time for shifting as above, at an average cost of 8s. 8d. per acre, including men, coal, water, &c., as above: to this must be added interest of money and wear-and-tear—say, 1s. 8d. per acre, which will be the

outside, the tackle coming in nearly as good as it went out. As to the value of the work, I give it you in the words of practical farmers who visited me: 'On the wheat stubbles the common plough is of no use against you. On heavy land the spade cannot equal yours. On bean stubbles one ploughing with yours is worth more than two with the common plough.'

This was a brief report of my work done in the autumn of 1856; and as soon as I had completed this work I provided myself with a book, in which I entered all the operations, both steam and horse power, giving the cost of each separately, and the total cost of seed-bed on each of my several fields, not forgetting the 1s. 6d. an acre for interest, &c., nor the kind of crop planted on each field; and I made like entries in it every year afterwards during my fourteen years under steam culture, ending with the harvest of 1869. Here is a summary of that book.

HEAVY LAND.—FIELD No. 1.

One ridge ploughing and subsoiling by steam power	£0	7	3
Ten smashings by steam power	3	6	8
Eight cultivatings by horses	0	16	0
One subsoiling by horses	0	3	0
Two ploughings with horses	1	4	0

£5 16 11

Or an average of 8s. 7d. an acre a-year. The cropping has been—Oats one, clover two, wheat four, swedes one, barley two, and beans four.

FIELD No. 2.

Two ridge ploughings and subsoiling by steam power	£1	0	4
Eight smashings by steam power	2	11	5
Two cultivatings and drilling at one operation by steam power	0	10	0
Five cultivatings with horses	0	11	6
Two subsoilings with horses	0	6	0
One ridge ploughing with horses	0	4	0

£5 3 3

Or an average of 7s. 4½d. an acre a-year. Crops—Beans five, wheat five, swedes one, barley two, and clover one.

FIELD No. 3.

Two ridge ploughings and subsoilings by steam power	£1	0	4
Eleven smashings by steam power	8	11	5
Three cultivatings and drillings by steam power	0	17	0
Seven cultivatings with horses	0	14	0
One subsoiling with horses	0	3	0
One ridge ploughing with horses	0	4	0

£5 9 9

Or an average of 9s. 3d. an acre a-year. Crops—Peas one, barley two, beans five, wheat five, and swedes one.

FIELD No. 4.

Two ridge ploughings and subsoilings by steam power	£0	17	5
Ten smashings by steam power	8	6	8
Three cultivatings and drillings by steam power	0	17	0
Nine cultivatings with horses	0	18	0
One subsoiling with horses	0	3	0
One ploughing with horses	0	12	0

£5 14 1

Or an average of 9s. 7d. an acre a-year. Crops—Wheat five, beans six, barley two, and swedes one.

LIGHT LAND.—FIELD No. 1.

Three ridge ploughings and subsoilings by steam power	£1	10	6
Five smashings by steam power	1	11	5
Three cultivatings and drillings by steam power	0	19	0
Seven cultivatings by horses	0	14	6
One subsoiling by horses	0	3	6
Two ploughings by horses	1	1	6
One ridge ploughing by horses	0	4	0

£5 2 11

Or an average of 8s. 9d. an acre a-year. Crops—Beans three, wheat five, roots two, barley two, clover one, and peas one.

FIELD No. 2.

Two ridge ploughings and subsoilings by steam power	£1 0 4
Five smashings by steam power	1 13 4
Two cultivatings and drillings by steam power.	0 12 0
Six cultivatings by horses	0 12 0
One subsoiling by horses	0 3 0
Three ploughings by horses	1 8 0
One ridge ploughing by horses	0 4 0
	<hr/>
	£5 19 8

Or an average of 8s. 0½d. an acre a-year. Crops—Wheat three, wheat five, clover two, beans two, and barley two.

FIELD No. 3.

Three ridge ploughings and subsoilings by steam power	£1 7 7
Six smashings by steam power	2 0 0
Ten cultivatings by horses	1 2 0
Two subsoilings by horses	0 6 0
Two ploughings by horses	1 1 0
	<hr/>
	£5 16 7

Or an average of 8s. 4d. an acre a-year. Crops—Wheat five, roots three, barley two, beans three, and clover one.

FIELD No. 4.

Four ridge ploughings and subsoilings by steam power	£1 17 9
Two smashings	0 13 4
One cultivating and drilling by steam power	0 7 0
Four cultivatings by horses	0 10 0
Two subsoilings with horses	0 6 0
Four ploughings by horses	1 15 0
	<hr/>
	£5 9 1

Or an average of 7s. 9½d. an acre a-year. Crops—Wheat five, beans three, roots two, barley two, and clover two.

FIELD No. 5.

Three ridge ploughings and subsoilings by steam power	£1 10 8
One smashing by steam power	0 6 8
One cultivating and drilling by steam power	0 7 0
Six cultivatings with horses	0 12 0
One subsoiling with horses	0 3 0
Four ploughings with horses	1 11 8
One ridge ploughing with horses	0 4 0
	<hr/>
	£4 14 8

Or an average of 6s. 9d. an acre a-year. Crops—Clover three, wheat five, beans two, barley two, and roots two.

FIELD No. 6.

One ridge ploughing and subsoiling by steam power	£0 7 8
Three smashings by steam power	1 0 0
One cultivating and drilling by steam power	0 7 0
Nine cultivatings with horses	1 0 0
One subsoiling by horses	0 3 0
Three ploughings with horses	1 11 8
One ridge ploughing with horses	0 4 0
	<hr/>
	£4 12 9

Or an average of 6s. 7½d. an acre a-year. Crops—Wheat four, clover three, oats two, roots one, barley three, and peas one.

My land was not clean at starting, but it is clean now. The heavy land part of my farm under horse culture had a dead fallow every fourth year; under steam culture it has had none, yet it is clean.

The turn-over plough has not been in Nos. 2 and 3 heavy land during the whole period of 14 years. It has been upon No. 1 twice, and No. 4 once, and that is all, thereby proving that the plough on heavy land under steam culture is of little or no use. On the light land part of my farm it has been more used—twice on No. 1, thrice on No. 2, twice on No. 3, four times on No. 4, four times on No. 5, and thrice on No. 6; worked on all by horse power, thereby showing that on lighter soils it is more needed.

The average cost of seed beds, as may be seen above,

has been on the heavy land 8s. 8d. an acre, and on the lighter land 7s. 4½d. an acre. Under horse culture the former would cost over £1, and the latter would cost near upon £1 per acre; therefore I have effected a great saving.

The saving in horse keeping has been very great. Under horse culture I used six to work my farm, not over 6 in. deep. Under steam culture I have only kept three, and they on an average have worked only 118 days a-year. Now, if we fix the cost of the keeping of a horse, with shoeing, &c., at £25 a-year, exclusive of the value of its manure, I save £75 a-year by the reduction of six horses to three. This, for 14 years, gives a total of £1,050, the cost of two complete sets of tackle—even three sets, if we set off half the engines to thrashing.

The increased produce question I went into in August last, in a letter that was published, showing that it had been quite two quarters per acre upon my heavy land. Therefore, if we calculate it upon my 40 acres of heavy land, leaving the light land unnoticed, we get a gain of 80 qrs. a-year for 14 years, which gives a total of 1,120 qrs., and at 40s. per qr., a value of £2,240.

You see that there is not only a saving in the cost of seed beds, and in the keeping of horses, but there is also on heavy clay land a great gain by increased produce, and the land can always be kept clean and ready for crop at the cost shown above, provided the work is done at the proper time.

Will the landlords and farmers of England, with these facts before them, still turn a deaf ear to what I say, and let their 800,000 acres of dead fallow, as shown by the Board of Trade, still remain under dead fallow, when a mere 8s. 8d. an acre could work and keep it clean for ever?

By this summary it may be seen that I worked a combined cultivator and drill. I must explain this:

In 1861, it occurred to me that such an implement would be useful, I therefore set to to contrive and have one made, and in February, 1862, I tried it on No. 1 light land, that had been smashed in the autumn by cross-cultivating and drilling in the beans at one operation. It did its work well, and I had a capital crop, but the cost and weight of the machine was a drawback—cost £70, weight 1½ tons. In the March following I worked it again on No. 6 light land, that had been roots, fed on, cultivating the land without any previous operation, and drilling in the barley at one operation. This did well, and I had a good crop. I also that same year cultivated and drilled barley into No. 4 heavy land, after swedes, fed on, and this was done well without any previous operation, and I had a good crop. In 1863, No. 2 heavy land after beans was cultivated and drilled in wheat without any previous operation. No. 2 heavy land was cultivated and drilled in barley, after swedes, at one operation, without any previous operation. No. 4 heavy land, after being smashed in the autumn of 1862, was in the February following crossed and drilled beans, at one operation. No. 1 light land after beans was cultivated and drilled wheat at one operation, without any previous operation. No. 2 light land, after roots was cultivated and drilled barley at one operation, without any previous operation. All these crops proved good ones, and I so liked the machine and the kind of work that I set to and contrived a new machine, and had it made more than half a ton lighter in weight, and £30 less in cost, and the year following I worked it thus: No. 4 heavy land after beans, cultivated and drilled at one operation and that was all for the crop. No. 4 light land wheat after beans. The land was cultivated, and the seed drilled in at one operation, and that was all. The crops this year were good. In 1865, the machine planted the wheat on No. 3 heavy land, and on No. 5, light land: these crops did

well. In 1866 I did nothing, for I began to see that this kind of work would not do, for knot grass and other objectionable weeds began to put in their appearance, the land having lost the effect of a dry smashing in the autumn, but for all that I tried it again the next year, 1867. In No. 2 heavy land the wheat was drilled by the machine, cultivating the land at the same time, and so was No. 3 heavy land, and so also was No. 1 light land. No. 2 light land was smashed first and then crossed, and drilled wheat at once. This was the last that the machine did, for although the crops proved good my land became full of knot and other grasses, so much so that if I had kept on upon this plan I must soon have had a

fallow, therefore I condemned the machine. The wet seasons of 1866 and 1867 no doubt had something to do with these grasses, but an implement that cannot keep land clean in wet seasons will not do for me. I fell back upon the smashing one year for wheat, and the ridging and subsoiling the other for beans and soon righted myself; and if I had not have told this tale now, the people would not have known that dirty grasses were creeping in upon me in 1866 and 1867, but I tell it to guard others against ever attempting the do too much "system."

Now, I will show and explain the implements that I do like:

This is my ridger and subsoiler with which I started in 1855. It is a ridging plough and subsoiler, arranged in a strong frame, with a pair of wheels in front and another pair at the middle of the framing to regulate the depth, and the front wheels are also the guiding wheels. There is also an additional pair of wheels to raise the plough at lands end. The subsoiler being set so as to penetrate 4 or 5 inches deeper than the bottom of the trenching plough. By this operation the land is

trenched, subsoiled, and laid up dry for the winter more effectually and in better style than is done in our gardens with a spade. I never had a failing crop from work done by it, and the after operations for the succeeding crop have always been found light. The implement is but little known, therefore I am the more desirous of giving it here to make it more generally known, and the more so as the work done by it is vastly valuable.

This is my amasher, with which I started in 1855. It has three tines arranged in a strong frame, and the depth of working is regulated, and it is guided the same as my ridger and subsoiler. It is a very valuable implement for breaking up bean and pea stubbles in the autumn. It clears a width of from 30 to 36 inches. I continued to work it for several years; but, after giving £100 and my seven-horse engine for a more powerful engine, I had con-

structed a very powerful five-tined implement upon the same principal, covering a width of 48 inches, with which I can with the more powerful engine average 8 acres a day; whereas, with the three-tined implement and seven-horse engine, I could do only 5 acres a day, therefore the cost of operation is brought down from 5s. 2d. to 3s. 2d. an acre.

This is my subsoiler, with which I subsoiled round the ridges under horse-culture, before I adopted steam-power, and which I find very useful now.

Now, I will explain how I use them. My field No. 1 (heavy land) was worked after a crop of wheat with the ridge and subsoiler. The land lay in the state in which the implement left it until February (a careful man previously to this having walked every ridge, and took everything objectionable in the shape of dock or twitch, &c., from it: 3 acres a day is not more than a short winter-day's work at this job), when I planted the bean one row on each side the ridge. This placed the rows from 18 to 20 inches from row to row. After planting, the land was harrowed, to pull down the ridges, and cover in the beans. The beans were hand-hoed over three times, to keep the land clean from seeding-weeds, and I had a good crop of beans. As soon as the beans were harvested, I set my amasher to work to pull up the bean stubble, and cross-cultivated it with horses, and that was all that was done to it before planting it with wheat. Next year this field will be ridged and subsoiled again for beans, and go through the same process as it did for the preceding crop of beans, and so on—wheat and beans as long as I live.

Now, I will leave the heavy land, and go to the light field No. 1. It was wheat last year, and has been manured and ridged and subsoiled for roots next year. A careful man will look over it in the winter, and take everything objectionable away. He will do 8 acres a day, I am certain. In March I shall put four horses to work to pull my subsoiler along every ridge, and thus split them. The part for mangolds I shall pass a harrow over, and drill in the seeds; and the part for swedes will get a cultivating once over in April afterwards (a harrowing or two), and the seeds will be drilled in. The horse subsoiler does more than the splitting of this ridged land for root; for with it and the common plough I ridge up and subsoil all my headlands round my ridged work, and in a dry spring I may on my heavy land split my ridges before planting the beans. This in dry weather in February is a very good operation.

In 1858 I addressed a letter to the farmers of England, from which I now make the following extract:

"If steam power is to be generally applied to the cultivation of the soil, every large farmer must possess a set of apparatus of his own. Two or three small farmers may have a set between them, or hire one of another, according to arrangement, for September to October will not wait, and if the work is to be done well it must be done in those months. My own experience convinces me that one operation of the cultivator in those months does on clay land produce as good an effect as two ploughings."

This shows plainly how thoroughly I was impressed with the necessity of doing our work in September and October.

I reprinted this extract twice over in my revision of "Facts of interest to the Farmer," which shows plainly that in 1866 I felt the necessity of doing the work in those months as much as ever, and in my remarks on my fourteen years' summery it may be seen that I insist upon having the work done at the proper time. This shows clearly that I cannot be driven from the point; neither shall I, for I know that the prosperity of the farmer under steam culture depends upon it, and so to some extent does the price of bread to the people.

I have sketched the road that led me on to steam. I then show my start and first year's practice; and then I give a summary of my fourteen years' practice, with some remarks thereon; I then show the rise and fall of my combined cultivator and drill; then I show and explain my implements; then I explain how I work them; and then I show that I addressed the farmers of England, impressing upon them the necessity of getting the work done in September and October; and now I must show that on the 29th of September, 1869, I had a new start under altered circumstances, having bought another farm (sixty-one acres of heavy clay) adjoining my old heavy clay land (ten acres of this is grass and fifty-one acres arable), and seventy acres of grass land upon the flat, near to my light land. I have thrown the two lots of heavy land together, and therefore a new book of re-

ference was needed, and to make my position now quite clear as to cost of working, &c., I will give a copy of it, showing the cost and all particulars as to the work done this autumn for next year's crop, which are not included in my summary for my fourteen years' practice. Here are the particulars:

September 15, 1869.—Finished harvest.

21.—Started the smasher on part of No. 8, heavy land, 20 acres.

22.—Worked all day.

23.—Finished the 20 acres at 10.55 a.m.; then shifted the tackle to No. 2 heavy land, and started.

24.—Worked all day.

25.—Finished No. 2 heavy land at 5.10 p.m., 22½ acres; then shifted to No. 1 heavy land.

26.—Sunday.

27.—Worked all day.

28.—Worked all day.

29.—Finished No. 1 heavy land at 8.20 a.m., 16½ acres. The men were at dung-cart the rest of the day.

30.—The men at dung-cart all day.

October 1.—Tackle shifted to, and started on light land No. 6, working the ridges and subsoiler.

2.—Worked all day on No. 6.

3.—Sunday.

4.—Finished No. 6 (14 acres) at 11.20 a.m.; then shifted, and started the ridger and subsoiler on No. 1 light land.

5.—Worked all day.

6.—Finished No. 1 (12 acres) at 8.20 a.m.; then shifted the tackle, and set the smasher to work on No. 4 light land.

7.—Finished No. 4 (12 acres) at 11.50 a.m.; then shifted the tackle to No. 5 light land, setting the ridger and subsoiler to work.

8.—Worked all day on No. 5.

9.—Finished No. 5 (12 acres) at 11.15 a.m., and then packed up the tackle for the year.

The total consumption of coal has been (for the 109 acres) 9 tons 18 cwt., or an average of 1 cwt. 2 qrs. 17 lbs. per acre. A boy only fifteen years of age worked the implements during the whole period.

I have noticed Sundays and dung-cart to make it quite clear as to the working days. It may be seen that I have smashed 71 acres in 8½ days, and that I ridged and subsoiled 88 acres in 6½ days. The former was done at a depth of 6 inches, and the latter from 10 to 12 inches. Now I must give a day's working expenses when working the ridger and subsoiler:

	£	s.	d.
Engine man	3	6	
Windlass man... ..	2	6	
Two anchor men	5	0	
Fifteen-year-old plough-boy	1	6	
Plough-boy assistant	2	6	
Two roller-boys	1	6	
Water-fetcher... ..	2	0	

18 6

The plough-boy's assistant is not needed with the smasher, therefore the cost for men at that work stands at 16s. per day. The average daily consumption of coal was 11½ cwt. and a fraction: 99 cwt. to smashing, and 79 cwt. to ridging and subsoiling. The seventy-one acres of smashing in eight-and-a-half days stands thus:

	£	s.	d.
Men for 8½ days, at 16s. per day	8	16	0
Coal, 4 ton 19 cwt., at 16s. per ton... ..	3	19	2½
Oil, at 9d. per day	0	6	4½

£13 1 7

or an average of 3s. 2d. per acre, yet not quite, for I had

thrown the fractions away. This shows plainly that much as I liked my seven-horse engine and three-tined cultivator at my start, I acted wisely by giving the seven-horse engine and £100 for my powerful one, and by having a powerful five-tined cultivator made, clearing a width of 48 inches; for by this move I have reduced my cost for men and coal from 5s. 2d. to 3s. 2d. per acre, and when 1s. 6d. is added for interest of money and wear-and-tear, the total cost for the operation per acre is only 4s. 8d., and when a cross cultivating by horses is added to this, the total cost of a seed bed for wheat stands at 6s. 8d. per acre, and that is all on my very heavy land.

The 38 acres of ridging and subsoiling in 6½ days stands thus—

	£	s.	d.
Men for 6½ days at 18s. 6d. per day	6	4	10½
Coal, 3 tons 19 cwt., at 16s. per ton	3	3	2½
Oil at 9d. per day	0	5	0½

£9 13 1½

or an average of 5s. 1d. per acre, and a very little fraction over. If you look back you may see that my average of this kind of work at my start stood at 8s. 8d. per acre, excluding 1s. 6d. per acre for wear-and-tear; therefore my position here is greatly improved by using a more powerful engine, and when 1s. 6d. per acre is added to the 5s. 1d. per acre, at which this operation now stands, we get a total of 6s. 7d. per acre for ridging and subsoiling my heavy land 10 inches deep—the cost of a seed-bed for beans, for that was all I did on my heavy land last year.

The 1s. 6d. per acre for interest of money and wear-and-tear passed unquestioned through my fourteen years' practice; yet at the end of my work done for my fifteenth crop, it was questioned, and well it might, for it stood forth with 3s. 2d. an acre, for men, coal, oil, and water as the working costs, and 2s. an acre for cross cultivating with horses, to represent the total cost of a seed-bed for wheat on my heavy clay land, at 6s. 8d. an acre, while under horse culture this very land would cost quite 14s. an acre to plough it over once. I have repeatedly explained the matter, and I will give the explanation here, for the public have a right to know all about it. Here is my position at starting—

	£	s.	d.
Dec. 1855.			
Seven-horse engine	300	0	0
Windlass, &c.	80	0	0
Two implements made by my own blacksmith	18	0	0
Alteration of engine and windlass, new anchors, &c.... ..	33	0	0

£331 0 0

From this must be deducted the half of the engines, to be placed to thrashing, £100; and the sale of three horses £150, to make room for the engine; this fixes the balance of £81 as the extra tenant's capital needed at starting.

At my start I did 25 acres, and in the March following I worked 12 acres over twice on my heavy land and planted it with peas, which gave me a produce of 5 qrs. per acre, value £10 per acre. This field under horse-culture would have been dead fallow. After harvest, I worked again, and on the 13th Nov., 1856, I wrote to the *Mark Lane Express*, as I have before shown, but I will quote a few words here from that letter, to show what I said upon the interest of money and wear-and-tear question. "To this must be added interest of money and wear-and-tear, say 1s. 6d. per acre, which will be the outside, the tackle coming in nearly as good as it went out." The quantity of work done in the autumn of 1856 was 66 acres. When writing to the *Mark Lane Express* (I took into consideration the £100 for the half

of the engine for thrashing, and the £150 for horses sold off, and as there would be only £4 1s. due for interest on the extra tenant's capital needed at the following Christmas; and that I should have saved £75, the keeping of three horses sold, and thus gained enough in that way to pay, not only the interest, but nearly all the extra tenant's capital needed, and in addition to this I had got my £120 worth of peas instead of a dead fallow) I knew that I was using the word "interest" just to satisfy the public, who at that time made it a matter of necessity that that word must appear in all matters in connection with steam cultivation. The fact is the 1s. 6d. an acre represented wear-and-tear and depreciation, and I am quite certain that it was a fair estimate. It may be said that mine was a low-priced set of tackle at starting. True! but it answered my purpose well as an experimental set. I have it by me now, and am proud of it, it being the first that worked land practically by steam power, yet for the last ten years I have worked a four-wheeled one; but to make matters quite plain and fair, I will show my case in another form, by making a fresh start on the 29th of September, 1869, when I entered upon my new occupation, bringing my total arable land up to 163 acres, showing the number and cost of horses, &c., that would have been needed to work it by horses only, and the number and cost of horses, &c., with the cost of an engine and a set of steam tackle to work it upon the Woolston system. I fix the cost of a horse with its tackle and implements to work with, at £45, the cost of an engine at £300, charging the half of it to thrashing; the cost of a set of tackle, with a five-tined smasher and a ridger—the two implements I use—at £216, the price at which they are offered by the makers to the public, and the cost of the keeping of a horse at £25.

My 163 acres of arable land consists of 90 acres very heavy clay, hilly and uneven; in fact, there are five hills upon it, all at points very steep, and 73 acres of what I call light land, but in fact is not so. It is upon the flat, mixed gravel and clay. Under horse culture, to work the whole 6 inches deep 10 horses would be needed; under steam culture, to work it 10 inches deep on the heavy clay part and 12 inches deep on the lighter part I have started off with 5. That number will not get half employment throughout the year, as I have a lot of landlord's work to do, and I mean to be well up to the mark for doing all, both landlord's and tenant's for at least this year. The case stands as follows:

STEAM-POWER CULTURE FROM MICHAELMAS 1869 TO
MICHAELMAS 1870.

Half the cost of the engine	£150	0	0
Cost of tackle	216	0	0
Cost of 5 horses, with implements, &c., at £45 each horse	225	0	0
Cost of keeping 5 horses at £25 each..	125	0	0
	£716	0	0

HORSE-CULTURE FROM MICHAELMAS 1869 TO MICHAELMAS
1870.

Cost of 10 horses, with implements, &c., at £45 each horse.....	£	s.	d.
Cost of keeping 10 horses at £25 each	450	0	0
Balance on the side of horse culture...	250	0	0
	£716	0	0

Therefore £16 more tenants' capital is needed to work this 163 acres farm of mine the first year, having the

whole in crop, than would have been needed under horse culture, having a portion fallow. The interest on the £16 extra tenants' capital needed is but a mere trifle, and the increased produce under steam culture can well afford to pay it.

Now, there is a point about this tenant's capital that is under consideration worth looking into, the word "interest." Interest is never charged on horses, their tackle, and implements, or on money for payment of labour. When a valuation is made horse-keeping is taken into account, their tackle and implements are also considered, and so is their doctor's bill, and the knowledge of now and then a dead hour is not tossed on one side; payment of labour is also considered, but interest of money never is. I will support my case by an extract from Mr. Morton's paper, read before the Society of Arts, p. 87, 1859:

"Now, the cost of horse-labour on 21 farms in different parts of the country, of which the particulars have been kindly given to me: Those farmers employ 282 horses, and they cost for food, for depreciation of value, and saddlers' and blacksmiths' bills £7,815 a year, their implements need £870 a year to keep them good, and the ploughmen and boys employed about them cost £4,241 a year in wages; about £13,000 in all, or £46 per horse per annum."

The farmers had to find this £13,000, yet interest upon it is not considered. Hereafter I will drop the word interest, for I have proved that extra tenant's capital on a moderate sized occupation of clay land where the Woolston system of steam-power culture is used is not needed. I shall use the word "extras" instead of "interest" to include in it what ever there may be, with wear and tear and depreciation.

The gains on the side of steam culture as carried out, by me are: increase of depth of culture, from 6 inches under horse-culture to from 10 to 12 inches under steam power culture, at a much less cost per seed-bed yearly, from quite £1 per acre under horse-culture to from 6s. 8d. to 10s. per acre. Under steam-culture a much cleaner system of working is got than under horse-power, the former never needing a fallow, while the latter needs one every fourth year on our clay soils. The result from all this is a great increase of produce, due first to having all the land in crop instead of a fourth part of it in fallow yearly, and the remaining is due to a greater fertility of the whole—in my own case full 2 qrs. per acre yearly on my heavy clay land, and my land is not exceptionally for the Board of Trade has shown that there are yearly 800,000 acres of fallow in this country on like soil to my heavy clay. These 800,000 acres must be multiplied by four to represent the quantity of land worked under the fallow system. This gives 3,200,000 acres of heavy land especially needing steam-power upon it, and if my data of gain is taken as a basis of calculation, and spread over this large quantity of acres, there is shown to be a clear gain of over £12,000,000 a year, to be had as gains of the country. Surely such a sum as that is worth trying for, especially as it can be won without any increased tenants' capital, excepting a little that must be lost in making the change from one system to the other. In pulling down a house and rebuilding it there is always a cost, be the old material ever so good; yet we seldom hear of regret or loss after it is done.

WILLIAM SMITH.

Woolston, December 18, 1869.

PLATE II.

DIADEM; A PRIZE HEREFORD HEIFER.

Diadem, a red with a white face, bred by Mr. W. Tudge, at Adforton, near Leintwardine, Herefordshire, and calved on August 1st, 1866, is by Chieftain 4th (2455); out of Deborah, by Pilot (2156), her dam Darling, by Carboneal (1525)—Daisy, by The Doctor (1088)—Dainty, by Orleton (901)—Pretty Maid, by Nelson (1921).

Chieftain 4th, a red with a white face, calved February 1st, 1864, was bred by Mr. T. A. Hollings, of Hill-end, Hereford. He is by Chieftain 2nd (1917), out of Rose of Weston, by St. Clement (2201), her dam Rose 5th, by Voltigeur (1445)—Rose 4th, by Byron (880), and so back to Rose 1st, by Young Waterloo (2341).

Deborah, a red with a white face cow, also bred by Mr. Tudge, and calved on August 3rd, 1868, has had three calves: Diadem in 1866; Dorcas, by Artist (2934), in 1867; and Duenna, by Dundee (3080), in 1868. She is still in Mr. Tudge's herd.

At the Leicester Meeting of the Royal Agricultural Society of England in 1868 Diadem took the third prize of £5 in the class of Hereford heifers under two-years-old; Mr. Arkwright taking the first, and Her Majesty the second with Duchess de Bronté. The judges wrote thus, "an extremely good class, containing several excellent animals."

At the Southampton Meeting of the Bath and West of England Society and Southern Counties Association, in 1869, Diadem took the first prize of £15 in the class of heifers in-calf or in milk not exceeding three years old, beating Mr. Arkwright's Lady Leicester, and two heifers of Mr. James', both of which were commended. We thus wrote in our report of the meeting: "There was a

small but excellent class of heifers in-calf, where the Leicester awards were reversed; Mr. Tudge's Royal third being now put first, and Mr. Arkwright's first being here next best. And we certainly prefer the second reading, as no doubt the Hereford awards at Leicester were very open to comment; or, at any rate Diadem must have vastly improved in the interval, for she is at this showing by far the better looking of the two, being really handsome."

At the Manchester Meeting of the Royal Agricultural Society of England, Diadem took the first prize of £15 for heifers in-milk or in-calf not exceeding three years old, beating Mr. Rogers' Queen of the Valley (2nd prize), Her Majesty's Duchess of Bronté (3rd prize), and Mr. Arkwright's Lady Leicester (highly commended). As we then said, Diadem had "continued to improve, being now a very sweet, straight heifer, of particularly fine quality." The judges here again "considered the two-year-old Hereford heifers excellent representatives of the breed."

The Adforton herd was in great force at Manchester, where Mr. Tudge took first prize for bull calves, second for cows, and first for heifers in-calf, yearling heifers, and heifer calves. As we said there and then, "no doubt Mr. Tudge is a famous doer by his stock, for he shows in high flattering condition; but he would seem to have discovered the secret of knowing just when to stop, as his animals neither fade nor grow gaudy." Diadem and the bull calf, Ostorious, were purchased at Manchester by Lord Southesk, and are now located at Kinnaird Castle, in Forfarshire, where they are replacing the black Polled with the Whitefaces.

EARTH COMPOSTS.

BY CUTHBERT W. JOHNSON, F.R.S.

The deodorizing power of earth has been well known from a remote period. Every cat, where it used a rough kind of earth-closet, evinced this fact. This knowledge was not confined to the Old World. The natives of Northern America devoured the skunk, a most intensely stinking animal. Before, however, they cooked it, they removed the odious smell by burying it for a time in the earth. It is therefore absurd to announce as a discovery the use of earth as a deodorizer. Still more absurd is it to endeavour to promote the introduction of earth-closets by denouncing other, and far more extensively practicable modes of providing for the excreta of crowded districts.

At a season when much carting of manures is going on, it may be useful if we recur to a few facts relating to the formation of earth composts.

It is now some years since Mr. Huxtable and Mr. H. S. Thompson directed Professor Way's attention to this very important question. Mr. Huxtable had, in fact, made some experiments in the filtration of the liquid manure in his tanks, through a bed composed of an ordinary loamy soil. He found that after its passage through the filter-bed the urine was deprived of colour and smell; in fact, that it went in manure and came out

water. This of itself, as the Professor remarked, was a singular and interesting observation, implying, as it did, the power of the soil to separate from their solution those organic substances which give colour and offensive smell to putrid animal liquids. The Professor saw at once the importance of ascertaining the extent of this deodorizing power. He commenced a series of experiments, the results of which are recorded in the 11th volume of the *Journal of the Royal Agricultural Society*, p. 313 (see also a paper by Mr. H. S. Thompson, *ibid* p. 68). He tried the effect of passing some fluid from a London sewer through a filter composed of 4 lbs., equal to six inches' depth, of a red soil, from the Berkshire estate of Mr. Pusey. This soil contained in 100 parts—

Water	20.56
Vegetable matter	6.17
Sand and clay	59.00
Carbonate of lime (chalk)	5.94
Oxide of iron and alumina	7.90
Potash	0.31
Soda	0.12

The following table gives the contents in grains of an imperial gallon of this sewer fluid, before and after it had been filtered through the soil:

Diadem.

A Friesian Herford heifer, the property of Messrs. J. & J. Condit, of Alderbury, Wiltshire.

London: Published by Rogers & Telford, 265, Strand, 1870.

	Before.	After.
Organic matter and salts of ammonia	301.83	—
Organic matter	—	60.58
Sand and detritus of the granite from the streets	90.69	—
Soluble silica	13.51	—
Phosphoric acid	10.44	—
Sulphuric acid	14.73	—
Carbonic acid	15.59	—
Carbonate of lime	—	104.98
Lime	24.53	—
Sulphate of lime	—	17.49
Magnesia	2.87	—
Peroxide of iron and alumina	6.20	—
Potash	48.13	—
Soda	1.51	—
Common salt	33.24	52.73
Chloride of calcium	—	8.89
Magnesium	—	.67
Loss on analyzing, &c.	—	3.16
Total	492.26	248.50

It will be noted from the result of this analysis that a considerable portion of the organic matters of sewer-water remains in the water which passed through the filter. Now in the sewage-irrigated meads near Edinburgh a steam engine has been erected to pump on to other meads the water draining from the meadows previously irrigated with the fluid as it flows from the sewers.

The alumina of the soil was found by Way to be the chief deodorizer, the silica and the salts of lime being far less powerful. So that, as he observed (*ibid.*, vol. ix., p. 374), this newly-discovered property of soils explains the variations in manuring operations which are made to suit the nature of the soil. Clay has been shown to be the active substance in retaining manure, and sandy and gravelly soils not possessing a sufficiency of clay are expected to be less retentive of manure. Such is the fact, and soils of this description are said not to "*hold manure*." On such soils manure must be applied more frequently, and in smaller proportions than on stiffer soils, where, owing to the retentive power of the clay, the manure for several crops may be safely deposited.

If these inferences are correct, the only way of permanently improving a sandy soil is to clay it; and it is notorious that the light sands of some parts of Norfolk are only made to bear remunerative crops by copious dressings of clay. And it may be observed in passing, that where a dressing of clay is required, it very often happens that the substance at hand is a marl, of which more than half is carbonate of lime, which (that is, the carbonate of lime) cannot be supposed to be a substitute for clay, inasmuch as although it is capable of improving the mechanical texture of a sand or a gravel, it has none of the chemical properties of combining with manure which clay possesses. In Norfolk this is frequently the case, and it would often pay the farmer to go a longer distance for real clay, rather than use that of inferior quality which lies under the surface. The composition, indeed, of the clays to which the landholder has access is of very great importance; for not only does this vary in most neighbourhoods, but the same stratum also is very different in composition at different depths. We may usefully recur to the result of a few of the examinations which have been made of various clays. For instance, an apparently uniform clay being analyzed by Professor Phillips (*ibid.*, vol. vii., p. 258), was found to contain—

	At 22 in.	At 54 in.
Silica	59.0	72.9
Alumina	23.5	13.4
Peroxide of iron	8.1	6.6
Carbonate of lime	1.0	0.8
Water, sulphate of lime, &c.	4.8	5.5
Carbonate of magnesia	0.0	9.8

The following is the analysis, by the late Professor Johnston, of four varieties of good clay, 1 being from Cattle Hill, near Dumfermline; 2, from Sherburn Hill, near Durham; 3, from Tullarone, county of Sligo; 4, from Portobello, near Edinburgh (*Quar. Jour. Ag.*, 1847, p. 81)—

	1.	2.	3.	4.
Silica and sand	64.14	61.09	66.16	53.95
Alumina	13.54	19.91	16.08	25.55
Oxide of iron	7.57	6.75	8.38	8.08
Lime	1.90	3.36	1.88	0.88
Magnesia	1.31	2.38		1.61
Potash	1.86	2.33	1.83	1.54
Soda	0.68			
Sulphuric acid	1.37	—	—	—
Carbonic acid	—	3.68	—	—
Organic matter and water	7.82	—	4.89	8.60

It was in the course of his experiments upon the action of burnt clay as a manure, that Professor Voelcker examined the composition of a clay in its natural state, and after it had been exposed to the action of fire (*ibid.*, 1851, p. 105). He gives the analysis of portions of clay examined in four different states, viz.: I., in its natural state, as obtained from the new red sandstone, at Huntstile, near Bridgwater; II., the same clay, after being exposed to a dull red heat for half-an-hour, in a *closed* crucible; III., the same clay exposed to a similar heat in an *open* crucible; IV., the same clay exposed to a full red heat for three hours, in an *open* crucible. The results will be found in the columns marked in the following table:

	I.	II.	III.	IV.
Water	5.539	9.160	9.200	9.300
Organic matter and water of combination	3.621			
Insoluble matter (in hydrochloric acid)	84.100	80.260	81.845	85.309
Soluble matter, consisting of soluble silica	1.450	1.390	1.580	1.150
Oxide of iron and alumina	3.070	8.245	6.092	2.970
Carbonate of lime	0.740	0.480	0.560	0.188
Potash	0.269	0.941	0.512	0.644
Soda	0.230	0.336	0.314	0.104
Phosphoric acid	0.380	0.165	0.128	—

The reader will remark how materially, by burning, the proportion of soluble potash is increased in the clay; and to this increase the Professor seems to attribute a chief good result from clay burning. He says, "The agricultural value of clay chiefly depends on the proportion of potash and soda which it contains. Potash is an essential element in all ashes of plants, and acts as a most powerful manure. The high price of the salts of potash unfortunately prevents their more extensive application in agriculture, and plants are therefore dependent, in a great measure, on the natural sources. The chief source of potash in ordinary soils is the clay, which forms part of almost all soils, from which, in gradual decomposition, potash is set free, and made available to plants." Some valuable experiments were made upon the clays adapted for tiles, by Professor Johnson (*ibid.*, 1847, p. 81). He found various infusible or fire clays to be composed: 1, from Cool Island; 2, from Stourbridge; 3, from Stanington; 4, from Howth, as follows:

	1.	2.	3.	4.
Alumina	30.8	38.8	40.9	23.3
Silica	46.2	46.1	43.0	67.96
Perox. of iron and manganese	8.4	—	—	1.19
Lime	—	—	—	1.8
Magnesia	—	—	0.1	0.63
Potash	0.4	—	—	—
Water	14.3	15.1	14.7	3.79

Our tile and brick clays, adds Professor Johnston, are usually red naturally, or become so when burned. This shows the presence of oxide of iron, one of the ingredients which tend to make them fusible. Many also contain lime, some in very considerable proportion. Magnesia is by no means uncommon, while potash and soda are always present in quantities more or less appreciable. It is the presence of these ingredients which gives to our bricks and tiles the burned, glassy, swollen, and porous appearance they occasionally present, and which at times, in the hands of a careless or unskilful fireman, causes them to run together into one melted mass.

Not only the ammonia of manure but the soil absorbs also the ammonia and other matters deposited in rain-water, and from the vapour contained in atmospheric air. Hence, as the Professor remarks in another place, when reporting his experiments on the water flowing from our land (*ibid.*, vol. xvii, p. 188).

The advantages to the soil of removing the land-water, which prevents the free circulation of the atmosphere, is self-evident. "Every acre of ground," adds the Professor, "which allows water to percolate freely benefits equally by the nitric acid and ammonia of rain. But whence comes the additional luxuriance which vegetation puts on when the land is abundantly worked? whence the Lois Weedon crops? Obviously Mr. Smith cannot be satisfied with the ammonia of rain; he must have some from the air also; and he gets it from the air in a far greater quantity than the rain could furnish. In fact (adds Mr. Hoskyns), he habitually expresses his obligations to *the dew*, as a more steady benefactor than the rain, in much the same terms as might express the relation of 'daily bread' to an occasional feast. But still the soil can absorb more ammonia than it acquires from the rain and the atmosphere, for Liebig calculates (*ibid.*, p. 287) that the soil of an acre 12 inches deep can take up of ammonia, in addition to that contained in it from long exposure to the air—

Thin land of Dorsetshire	90.880lbs.
Light red soil, Berkshire	9.420 "
Stiff white clay	17.040 "

We have in this paper directed our attention to the action of clay upon decomposing or ammoniacal manures. But another important portion of our inquiry is as to the fertilizing matters which certain earthy substances, in their natural state, contain. In many cases, the earths obtained from pits, or the sea shore, or sides of rivers, are valuable manures, from the calcareous matters they contain; the mud of other rivers abound with organic matters to an extent of which the adjoining landholders are little aware. Thus, the mud of the River Thames has been very recently carefully examined in several places between Chiswick and Crossness. It was in giving evidence in last July, before the Commissioners appointed to investigate the Thames impurities, that Dr. W. A. Miller stated that in conjunction with Dr. Olding he had analysed samples of mud taken from various portions of the bed of the Thames, from that of Barking Creek, and from the bed of the Roding above Barking town. The mud taken at Barking Creek contained 16.2 parts of organic matter, and 100 parts of this organic matter contained 8.1 parts of nitrogen. The proportions in the mud in the Roding above Barking town were as follows: Organic matter 17.8; nitrogen, 8.17. The average character of six samples of mud taken from the Thames between Chiswick and Westminster was—organic matter, 15.8; nitrogen 8.05, insoluble and organic matter 84.2. Six samples were also taken from the London, St. Katharine's, East and West India, Commercial, and Victoria Docks, and these gave the following figures: Organic matter 15.8, nitrogen 8.07, insoluble and mineral matters 84.2.

Samples from the deposits in the reservoirs at Barking and Crossness gave results as follows: Barking: Organic matter 58, nitrogen 4.27. Crossness: Organic matter 37.1, nitrogen 4.51. From the Horse End a sample of mud showed less organic matter than any of the others, the figures being: Organic matter 7.2, nitrogen 2.51. From the bank near the works of the Chartered Gas Company the sample taken gave the following analysis: Organic matter 14.4, nitrogen 2.84. At Barking town quay a sample of mud was taken which contained 25.4 per cent. of organic matter.

Such a mud as this, when drained, would make a capital compost with farm-yard manure; and would, in fact, if applied by itself, be an enricher of many soils.

Then, again, we have to consider what are far more available, the earths which are so generally found on our own farms. It was in a valuable prize essay "on compost heaps" that Mr. J. L. Morton had occasion to remark (*Trans. High. Soc.*, vol. xiv., p. 435), (and what he remarks I need not even attempt to give in any other language,) that on every farm quantities of earth, road-scrappings, ditch-scurings, and similar substances are more or less available for earth composts, and may be profitably employed. By the action of the plough on good soils more or less earth is always being deposited on the turning ridges. If this soil is allowed to accumulate for many years a much greater loss is entailed upon the farmer than he may have any conception of. Take a head and foot ridge, each say 200 yards in length and 15 feet broad, with a depth of deposited soil of 15 inches, and we have 833½ square yards. Allowing that a field 200 yards broad has ridges 400 yards in length, it will contain 16 acres 2 roods 4 poles, and with the turning ridges at each end, covered with carried soil to the depth above mentioned, there will be sufficient earth to cover the whole surface of the field to the depth of nearly half an inch.

This is no extreme example, for very often turning ridges are covered with a greater depth of carried soil than 15 inches, though the ridges are less than 400 yards in length. A top-dressing of half an inch of good soil will often change the entire nature of a poor dry field, and in any instance will make a great difference in the quality of land.

In the winter of 1846, from the foot ridges of a field of rich black soil, having considerable inclination of surface, I removed 500 cart-loads of earth little inferior in quality to police manure. The field had laid in pasture for more than 80 years, having previously been regularly cultivated. The soil in the foot ridge being partly alluvial and partly plough-carried, had remained the whole time the field was in grass, and by long exclusion from atmospheric action had become quite brown in colour. Here then were 500 loads of valuable soil locked up in a foot ridge for more than 80 years without doing scarcely any good to the farmer. A large portion of the earth so obtained was applied at once to the surface of a cold thin clay soil, and the great improvement it made on the herbage clearly proved that the loss sustained by its long dormancy had been considerable.

"In the autumn of 1849," continues Mr. Morton, "I had a better opportunity of testing the advantages which may be derived from mixing soil with different kinds of manures. A sheet of policy ground extending to about 60 acres had been in pasture for many years, and for various reasons it was deemed expedient in 1849 to allow it to produce a crop of natural hay. To prevent the deterioration of the soil it was necessary after the removal of the hay crop to give a top-dressing of various kinds of composts. On thinking of the various substances which might be used with advantage, my attention was directed

to a flat alluvial spot of ground in the centre of a plantation adjoining the land about to be top-dressed. A small run of water had formerly passed through the centre of this flat, and having periodically left deposits of rich soil it had accumulated to a depth of about 4 feet. It was covered with half-grown hard-wood trees; but as they were tolerably far apart, a great quantity of earth could be removed without disturbing the roots. Several hundred cart-loads of this were removed, and laid on the pleasure ground in heaps of from 8 to 10 loads. This was mixed with short manure (partially mixed with byre and stable-dung), lime, and soot. In the manure compost a layer of soil was laid at the bottom 6 or 8 inches thick, and over this was spread quite loosely a 6-inch coating of dung. With alternate quantities of earth and dung, the former about 9 and the latter about 6 inches thick, the heaps were drawn to a ridge like a narrow potato pit. After being mixed with soot at the rate of 1 cwt. to every 5 cart-loads, and turned over once, it was applied at the rate of from 12 to 18 tons per acre, according to the state of the land. Taking 15 tons as the average, the cost per acre was as follows:

Digging and carting 10 loads of soil	£0	3	4
5 loads of police manure at 4s. 9d.	1	3	9
3 cwt. of soot at 1s. 6d.	0	4	6
Mixing, turning, and carting, &c.	0	8	6
	£2	0	1

For this sum per acre a top-dressing was applied, which, along with the lime composts, so much improved the pas-

ture, that the annual rental was subsequently raised 10 per cent. above its former letting price, and left 12 per cent. on the outlay.

A large quantity of soil so obtained was also used with caustic lime, the composts being prepared in the usual manner. The proportion of lime to earth was as one to four, and with the former mixed up in a hot state an excellent compost was prepared at an expense of—

12 tons of soot, digging, and cartage	£0	4	0
3 tons lime shells at 12s. 6d.	1	14	0
Preparing, turning, and carting	0	8	6
	£2	7	0

From careful observations of the appearance of the pasture for several years afterwards, the lime compost seemed to give the most satisfactory results.

Such are a few of the important questions which relate to the use of earth composts, and we must not fail to remember that there are few clays, or sands, or calcareous strata, which are not valuable as dressings for our land. The chemist finds that almost all of them contain small portions of organic or ammoniacal substances; that they can often add to our soils a needed supply of other saline matters which are essential constituents of our cultivated plants; and, moreover, that they have the great advantage over organic manures, that their beneficial influence is not confined to at most a single rotation of crops, but that they *permanently* increase the fertility of the soils to which they are applied.

A REMEDY FOR RABBITS.

"You, Mr. Editor, long before my name ever appeared in print, did good service to the cause by speaking and writing against the game-laws. Do for once give us your advice as to how we ought to act and for what we should ask. Sketch out the sort of legislative enactment that will preserve legitimate sport, and at the same time put an end to the 'unmitigated evil of the over-preservation of ground game,' and you will confer a debt of gratitude upon thousands of suffering tenants, and cause the never-ending obligations of your faithful servant,—CLARE SEWELL READ."—"I hope, Mr. Editor, that you will put us in a way to obtain a better state of things, and if your proposition has the approval of the majority of farmers, we must all give up our pet notions, and go with the majority, as we shall get nothing unless we are unanimous in what we ask for." So wrote Mr. George Smythies, of Shropshire, in our Paper of last week, as Mr. Sewell Read from Norfolk had written in our previous number. We the more readily accept this complimentary challenge, and return thus early to the subject from the way which the question is still making throughout the country. If the Land difficulty of Ireland should come on, as it must, for grave consideration during the next Session, so most assuredly should, as most probably will, the Game difficulty of England also command the attention of the legislature. Both the gentlemen whose letters we have quoted turn to the proceedings of the Scotch farmers in evidence of how little may be expected from the want of unanimity which has characterized their deliberations. As Mr. Read put it, "The Scottish Chamber, divided into two exactly equal parts, is to wait upon the Lord Advocate to help him in preparing his promised measure for amending the Scotch game laws." And on Wednesday last this deputation waited on the Lord Advocate accordingly, when strange as it may sound, nothing would appear to have been more unanimous

than the recommendations they offered. Mr. Wilson the President on the one part, and Mr. Scott Skirving, as leading the opposition, went dead against the hares and rabbits. Mr. Wilson said: "There was what he might call a taunt with which they were constantly met when they complained of the grievances under which they laboured and the evils that resulted from the operation of the game laws. The taunt was this—'But you go and sign leases in which you make yourselves to blame for that.' Well, that just led him to impress upon his Lordship that the case was one in which they required to get redress by public means. The farmers really could not defend themselves." And Mr. Scott Skirving followed this up by declaring "he was entirely in favour of more stringent powers being given to the farmers to kill hares and rabbits, and of making it illegal for two men to enter into a contract by which the occupants of the land were to give up that right."

Now here is something to go on, as something that should be agitated for alike by the English and Scotch farmers. Let us make it illegal to afford the rabbit, more especially, any protection whatever. Let it be made impossible for a landlord to "reserve" such vermin; and let any man be at liberty to destroy these pests in any way he can. A Norfolk farmer, says with reference to the privilege given by Lord Middleton to his tenants to kill rabbits, if they do not resort to unfair means, "perhaps Lord Middleton's agent would be good enough to inform us what are unfair means of destroying such vermin." Precisely so. That monstrous clause in the model agreement of the Royal Agricultural Society defines the unfair means as a *dog*, while in another agreement it is a *gun*—and so forth. Then, at Bradford-on-Avon, the other day, four or five labourers were taken up for trying to get a rabbit out of a hole with a hooked stick. According to the keeper, "Three of the Miseses worked for Mrs. Wiltshire, the tenant. The land

was Mr. R. P. Long's, but Mr. Forbes, had the shooting. Witness saw the defendants in the ditch for nearly half-an-hour. There were plenty of rabbits all along that hedge." Here we have all the evils of the system. The shooting is let to somebody else, and the farmer's men dare not kill a rabbit, although there were of course "plenty of rabbits all along." Whereas, had the Mizens been killing rats or mice, or weasels, nobody would, as nobody could, have interfered with them. Nevertheless, rabbits do a deal more damage to the farmer than rats or mice or weasels, and to the level of rats and mice must they be reduced. As Mr. Scott Skirving says, it shall be illegal for any two men to enter into a contract to the contrary. Surely Mr. Sewell Read and Mr. George Smythies will allow that we may be unanimous so far, or at any rate we may command a majority when settling upon something to "ask for."

But we must go further still, and still with something like unanimity. On the day previous to the deputation waiting on the Lord-Advocate in Edinburgh, the game laws had been discussed at Birmingham, where Mr. Kidger, a farmer, said: "He had a right to destroy the rabbits. He planted a field in Feb., 1867, and on one side of it there was a wood, into which he had no right to enter. The rabbits came from this wood and destroyed three acres of the field near the wood, and also destroyed bits all over it about the size of that room, and the consequence was that in the last week in August he had suffered a great injury." And, again: "they talked about catching rabbits. He could not catch them—he did not know how. No man had a right to go on to another man's land to fetch game, and very frequently the vermin which did the most mischief came from adjoining lands." This is all terribly true; while, as to compensation, we may say here, as the late John Grey, of Dilston, said before a committee of the House of Commons, "I have never yet, where valuation and arbitration were resorted to, seen the farmer get one-half of what I consider he was entitled to." The rabbit then must be regarded as a nuisance, for the destruction of which men should be rewarded rather than punished; as of course there must be some penalty provided for those who harbour or encourage such nuisances. In towns and cities if a man pursue a calling to the injury or annoyance of his neighbours, he lies himself open to an information,

upon which he can be convicted. And some similar means must be taken to put down the nuisances of a country life. The rabbit is a nuisance, an animal we will say in the outset that is beyond the pale of the law, and anyone breeding or preserving rabbits is doing an injury to his neighbours, and must be dealt with accordingly. Again, it is to be hoped that we may come to an unanimous opinion as to what we should ask for. Lord Leicester in the upper, and Mr. Sewell Read in the lower House have declared that there is no farming against rabbits, so that any such reformation as is here proposed should carry with it the best of introductions.

Mr. Read "quite agrees with us that much may be done by talking the matter over;" but we confess that we begin to tire of mere talking. The President of the Scottish Chamber declares, indeed, that "the evil is not diminishing, but is rapidly on the increase. The number of proprietors preserving game was gradually becoming greater." And to meet this growing abuse, we must not merely make new laws but repeal others now in force. The correspondent of a Suffolk paper, writing on Wednesday last of some grand doings in his district, says, "At one of the battues, and probably at all of them, three or four of the county police were stationed day by day at different places on the outside of the wood to take care that none of the slaughtered game was taken away." Here is something more to be unanimous about, as most assuredly a large majority of the farmers will be ready to go against that infamous Game-keeper-Police Act, the most unwarrantable burden in the way of unfair taxation which has been inflicted for many years.

The Vice-President of the Council has, before this, called the attention of the House to the game evil, although Mr. Forster did not then hold the position, nor was he so well known as he has since become. Mr. Sewell Read says "more important and immediate subjects will stop the way of legislation," but we know of no question more important so far as the agriculturist is concerned; while we think, further, that the present Government is by no means indisposed to deal with the difficulty. The Lord Advocate said in Edinburgh, on Wednesday, that he would not fail to bring the matter forward.—*Mark Lane Express.*

THE MEMBERS IN COUNCIL.—R.A.S.

The Manchester Meeting of the Royal Agricultural Society of England in July last closed on the Saturday, and on the Monday, after protesting against the unwarrantable length to which the stock show had been extended, we went on to speak thus: "Even beyond this the Council, not content with screwing every half-penny it could out of the visitors at the expense of the exhibitors, was good enough to let others take a part in the plunder. In fact, the conduct of the proceedings seemed to be mainly in the care of the Local Committee, which coolly broke through the rules of the Society, and started exhibitions within exhibitions, and overlaid the show itself with absurdities, only to get more crowns, half-crowns, and shillings out of the unfortunate public. The Council of the Society was careful to announce that it had nothing to do with these fooleries beyond the chief officers gracing the performances with their presence. These distinguished personages rode or marched in procession at the head of the lists like a goodly company of Trumpeters, and incessantly testified to the great kindness and invincible energy with which the Local Committee devised schemes for making capital out of the

Royal Agricultural Society. A bonus of a thousand pounds or two should thus be no such bad a speculation in the end, the more especially when dealing with men who appear so ready to sell their rights for a meas of potage as the executive of these rural interests." We further characterized the extra charge imposed for admission to the jumping-ground as "a pretty little swindle," and we stated that this job would have come prominently before the General Meeting as held there and then, had not the mob broken in and upset the proceedings. On the Thursday, however, in the recent Smithfield Show week there was another General Meeting when this matter did come in for some discussion. Mr. T. Willson (from Leicestershire) said several members had determined to withdraw from the Society if such a business were ever repeated. They considered it a disgrace to the Society that such a thing should be allowed in order to compensate or please a Local Committee. It was quite beneath the dignity of such a Society—and so forth. Mr. Jonathan Grey, a man of much experience in this way, said that if the horses that jumped competed for the prizes of the Society, it was beneath the dignity

of the Society to allow them to go out of the yard for that purpose; and Mr. Duckham thought that the members of the Society had a right to see everything that was entered in the catalogue during the hours the exhibition was open, instead of being caught, as it were, in a trap, and he hoped that the Council would not be dictated to again by a Local Committee. Of course, all this is so palpably true and self-evident that the interest at once centres over any answer or explanation that could be offered for so monstrous an abuse or delegation of power. This, though, was very easily arrived at. Mr. Torr said that Mr. T. Willson had fallen into an error; Mr. Jacob Wilson that Mr. Duckham was labouring under a mistake; and Mr. Thompson that the discussion should not be continued. For our own part, we can see no error nor mistake, save such as was committed by the Council of the Society, while we consider the discussion of any such mistake as coming peculiarly within the province of a General Meeting. Mr. Torr said the jumping business was the result of a *private* arrangement. Was there ever such an absurdity advanced! How could there be a private arrangement with a public body? A private arrangement that interfered with a public exhibition, and that went to establish another public exhibition! The feeling of the Council, said Mr. Torr, was decidedly against the jumping, and yet the Council countenanced such a business on its show-ground. But then, as Mr. Torr went on to explain, their Manchester "friends" made this a *sine quid non*, from which, of course, it must be inferred that a Local Committee is the superior power of the two. The Council may be decidedly against bull-baiting, but if a Local Committee make this a *sine quid non*, a bull must be taken out and baited accordingly. Then Mr. Jacob Wilson, with curious inconsequence, argued that a gentleman who paid his entrance saw everything in the yard that was entered in the catalogue, although in point of fact it was not so. On the great day there was a time when a man who paid his entrance could not see everything that was in the catalogue, if, more especially as a member of the Society, he had quite as much right to this privilege as even Mr. Jacob Wilson himself. It was, then, the rather Mr. Torr who was in error, and Mr. Jacob Wilson who was very much mistaken; while if Mr. Thompson would stop such a discussion as this, it must be only on the plain understanding that he and his fellows "will never do so any more."

In other ways the tone of the last General Meeting of the Royal Agricultural Society of England was very healthy and encouraging, as in strong contrast to the pitiful exhibition of last Christmas. It was there that a Mr. Sidney was suffered to attack the newly-elected Editor and Secretary after this fashion: "He (Mr. Sidney) now supposed that the motto of the Society or of the *Journal* was to be Science *without* Practice. He presumed that the Journal Committee had undertaken the duty of educating the new Editor. Many clergymen undertook the education of young men for a certain consideration. In the present case he presumed the Journal Committee were to educate the Editor; only, instead of his paying them for his education the Society was going to pay him £800 a year for learning. The Journal Committee would, he supposed, be seen going about like a hen with one chicken, instructing this gentleman in the elementary knowledge of agriculture." And over such impertinances as these there was of course "loud laughter" at the expense of the new man whose deficiencies and incapability were so smartly shown up. But within twelve months how great is the revulsion! If Mr. Sidney attended the General Meeting last week he must have heard that the best Editor that the *Journal* has had since

the days of Mr. Pusey is the gentleman whose qualifications Mr. Sidney, without of course knowing anything of them, thought proper to disparage. Surely never was there a contradiction so straightforward or so complete. As we said at the time, we believed that the Council or the Committee had selected the best man for the difficult post he was called upon to fill, if the election itself were scarcely so methodically conducted as it might have been. And we said this in the teeth of the Old Practical Farmers who were writing up their own sons for the place, and of the middle-aged book-worm farmers who were complacently quoting the names of themselves and their connexions as about the only pair of heaven-born Genii to whom such a duty could be entrusted. We did so immediately on its appearance, but we may here again take, as Mr. Sewell Read did, "the opportunity to express his sense of the marked improvement exhibited in the last number of the *Journal*, which he considered more practical and useful than any number that had been issued for a great many years." "Science *without* Practice," said Mr. Sidney of the new Editor in 1868, and "most practical and useful," says Mr. Sewell Read in 1869, of the new Editor's first number. Need we comment further, or need we venture on any comparison as to the practical authority of Mr. Sewell Read and of Mr. Samuel Sidney?

As regards the Oxford Meeting there is one other matter that requires looking to. Mr. Coleman, indeed, called attention to the want of arrangement in the implement trials. Judges are called on, they know what to do, and a day or two is often cut to waste before they can get to work. There would seem to be little or no order in keeping off the crowd, and there is generally some hazy ignorance observable amongst the officials as to whether catalogues can be supplied or not. Of course implement catalogues should be available to the public so soon as the implement trials begin, just as the stock catalogues are on sale when the judges go to work. Then the implement awards should be published through the Secretary or some responsible officer, and not left to anybody who chooses to volunteer for such a duty. Last year some very absurd mystery was maintained as long as possible, and it then transpired that the announcement of the implement awards rested very much with one of the judges, who is himself occasionally employed on a newspaper, and who communicated with such as he thought fit. All this is very wild work, but we have no doubt that as the new Editor gets into his collar he will see that a better system is adopted.

At the meeting of the Council on Wednesday Mr. Sanday, who acts perhaps more frequently as a judge than any other man in England, very becomingly moved a resolution to the effect that judges who are members of the Council should be paid their expenses when acting at the Royal Meetings. Mr. Milward, however, went more directly to the point when he moved that Mr. Sanday and Mr. Bowley be paid for their services at Manchester! The subject has been deferred, but if this retrospective measure of remuneration be carried, of course it cannot end here. Mr. Druce must be paid his expenses at Leicester, and so on, or rather back, until we get to Oxford once more. The rule, or bye-law, seems to us to work very well as it is. It must be something of an honour to be on the Council, and it must be something more of an honour to be a Royal judge; as even further, there are two or three members of the Council, who are continually during the show season acting about as judges, although, according to pretty general opinion, their qualifications in this way are not so extraordinary.

THE LATE MR. GEORGE SAVILLE FOLJAMBE.

There is scarcely a man in the Midlands, for whom the name of "George Foljambe" has not a familiar sound. The older ones remember "The Squire" of Osberton, in his scarlet-and-velvet cap, cheerily picking it out over the clays, with his Sparkler, Herald, and Harbinger, of the Ranter blood, to the fore, while the younger ones only knew him in his green coat and white hat, &c., his once-piercing dark eyes sightless and downcast, leaning on his son's or some old foxhunter's arm at Tattersall's, or "touching" the prize sheep at a show. Like two other great sportsmen of very different mould, the late Lord Derby and Earl Wilton, he was born with the century. His family tree had its tap-root in an old soil, as the deceased could trace his pedigree up to Sir Godfrey Foljambe, Knight of Walton, and Sheriff of Derbyshire in 16 and 20 Henry VIII. His grandfather's estate of Osberton became his own when he was only fourteen; and as soon as his majority was attained, he took to foxhounds. Bad-scenting country as the Grove may be, he did not care to roam elsewhere, and only twice for a short period he was beguiled away to Sir Tatton's and the Burton. The young master threw himself into his work with all his heart and soul. He entered his young hounds at Grove, Scofton, and Whitwell Woods, and he "finished the season's tuition" in the limestone country, on the Fitzwilliam side, when the clays were all baked.

At the time when he first carried the horn, Tom Sebright was still with Mr. Osbaldeston in Leicestershire; Charles Davis had not yet been gazetted as huntsman of the Royal Buckhounds, and received his King's orders to "breed them so fast that they can run away from everybody;" Mr. Ralph Lambton, with his boxwood horn, and his *Forard! Yi Haro!* and the Earl of Darlington on his grey Ralph were the Nimrods of the North; and John Scott was busy putting a polish on the Houldsworth lot in the quiet glades of Sherwood Forest. It was a day of mighty fox-hunters—of Tom Smith, John Warde, Musters, and Sir Richard Sutton; but the Young Squire of Notts soon made his mark, and as years went on, "Foljambe and Foxhunting" was a toast which always stirred the blood. The best kennels were glad to come to Grove for a change of blood; and many a quiet little parliament was held on its flags, and matches and sweepstakes for a roll of scarlet cloth decided, for which stakes had been made at Boodle's. If a master was forming a pack under difficulties, or had a loss in the middle of the season, Mr. Foljambe could generally help him out, as Mr. Tom Hodgson used to say, with "some waifs and strays." For a man who loved the sport so ardently, and cared only to watch the working of hounds, blindness was indeed "a sorrow's crown of sorrows," but marriage to his first love helped to lighten the blow, and break the double solitude of his life. He could still ride to cover, led by a servant, and listen when "so cheerily they found him, so gaily bustled round him," with something of his old rapture.

About racing he troubled himself very little; and although he always entertained Earl Zetland (who was his confederate during his three seasons on the turf), Mr. Williamson, and a large party at Osberton during the Doncaster week, he seldom cared to go with them, and spent the day with her ladyship, walking down to Scofton farm, or knitting garden-nets.

Later in life, Mr. Foljambe became more interested in his Scofton farm, and always kept well abreast of the times. With a difficult soil to till;

"He knew the auguries of coming change,
Of other ministrants in shrine and grange,"

and liked to have every machine about him of the best kind. No stacks were better thatched and trimmed; and in the driest season his agent, Mr. Woods, could invariably show a luxuriant green crop. Sheep were long his prime delight, and he loved to handle them as carefully as if they were a foxhound on his trial for the second draft. Nothing escaped him; and Mr. Jonas Webb was wont to say that he wished he could be made judge at the Royal and Smithfield Club for the term of his natural life. He had a flock of both Southdowns and Leicesters on his Park. The former were his favourites; but the latter for five years, in the teeth of very strong competition, took the gold medal or silver cup at the Smithfield Club. London and Birmingham were his Christmas fields, and this year he was not a little pleased when he heard that he had "split" Lord Walsingham

in the light-weight class of Southdowns and Lord Seades. Of late years, he had done a great deal with Shorthorns, and began his Booth blood by hiring bulls from Mr. Carr.

Robin opened the ball for him by beating, solely by his very superior handling, Mr. Fawkes's Friar Tuck, the first-prize Royal bull-calf, when they met at Doncaster; and Knights of the Bath and the Garter have made their names known since then in still wider fields. His white cow Cherry Blossom won a first prize at Smithfield last year, and proved to be in calf with a white heifer. About three months after calving she died very suddenly, and we believe that "The Squire's" last walk to his farm was to learn the particulars. This was about a month before his death, and he was soon afterwards seized with bronchitis, from which he could never wholly rally. Still, he retained his interest in all that was going on, and he saw both Mr. Woods and his herdsman shortly before his white ox and the Southdowns went to London, and inquired with much of his old zest if they seemed up to the mark. To those who had not seen him for some time he seemed to be gradually failing; but no great change took place until forty-two hours before his death, when he fell into a state of strange listlessness. Dr. Gull was consulted; but the strong man was bowed at last. He was buried at the church which he erected in his own park to the memory of his first wife, and on Thursday a large and sorrowful crowd—rich and poor commingled—from all the country round stood by "The Squire's" grave.

THE CIRENCESTER COLLEGE.—The College Club dinner was held at "The London," in the Show week, Mr. Holland in the chair. After dinner, a few remarks on one or two subjects connected with practical agriculture having been made by Dr. Voelcker, Mr. Kimber, and others, Mr. Coleman, who has held the only permanent appointment in connection with the club, that of Hon. Secretary, ever since the formation of the club at the Chester Meeting of the Royal Agricultural Society, intimated his desire to retire from his post and placed his resignation in the hands of the members. Although regretting his withdrawal, it was considered wise to accept Mr. Coleman's resignation, for there has been perhaps a too exclusive "old time" and "old student" character about the meetings, and to have appointed any one at present immediately connected with College, would have been working towards the other extreme. A most successful compromise, however, was made in obtaining the consent of Mr. Roberts to act as the future hon. secretary. This gentleman was at the College with the old staff and with the present; he holds the diploma of the College, and has only quite lately distinguished himself by obtaining the diploma of the Royal Agricultural Society. Mr. Holland being the chairman-elect for the Oxford meeting, it is to be hoped the club will now take a fresh start and go on and prosper.

The autumn session of the Royal Agricultural College closed on Friday, Dec. 17. The following awards were announced: Diploma to T. G. Lofthouse, York; W. W. Church, Circus, Bath; C. Wachter, Chislehurst Court, Canterbury; W. Searle, Chadlington, Oxon; J. Roberts, Boverly Tracey, Devon; H. G. H. Phelps, Ridley Wrotham, Kent. Scholarships were also awarded to Granados, Ashcroft, Willett, Smith, Ohrlay, and Woodgate. In a report, just issued by the surviving members of the Committee of Management, it is stated: "The college has not only become self-supporting (including payment of the interest of the £30,000), but there is a surplus available, after the payment of that interest, to provide a sinking fund for the gradual sinking of the debt. The Earl of Ducie, in furtherance of the views of his late father and of Mr. Langston, and to show his own appreciation of the advantages of the college, has kindly expressed his readiness to co-operate with us in the present attempt to place the institution on a permanent basis; we also confidently anticipate the co-operation of other noblemen and gentlemen who are interested in the extension of sound agricultural education. Our object is to bring to a close the provisional arrangements which were forced upon the college, when its affairs were in a very unsatisfactory state twenty years ago; and now, when its prosperity seems to be secured, to return to the proprietors the trust which they then committed to us, and to settle, with their concurrence, the future government of the institution."

ARTIFICIAL MANURES.

Of the several materials which vegetation requires for promoting successful growth, there is one class of bodies known as the silicates which have most important duties to discharge. These are all compounds in which silica enters into combination with other bodies. In general terms it may be said that as the phosphates give firmness and rigidity to the skeleton of the animals, so do the silicates give stability to the vegetable tissues, and thus contribute to the perfect development of the plant. In some cases we find that where exceptional strength is needed or special protection is necessary, there the silica is particularly abundant. The stalk of wheat is a special instance of this kind, for not only have the tissues of the plant received their ordinary supply, but a coating of silica surrounds and strengthens the straw and enables it to carry its heavy load.

An examination of the ashes of plants has shown the presence of silica in every cultivated plant, and that it constitutes a large proportion of the mineral matter taken up by growing crops. It is, therefore, an essential of successful growth. All our soils contain a large supply of silica, some in a condition readily available for vegetable growth, and much becomes so by the processes of cultivation and the action of manures. The question very naturally arises, is it necessary to make any special provision for the supply of a body which is so generally abundant? The inquiry is just, and shall be fairly met. To facilitate this explanation it should be stated that silica generally exists in our soils combined with alumina, in which form it is insoluble in water, and therefore so far valueless to vegetation. There are, however, various agencies by which it is made available.

Of these agencies the most influential is undoubtedly the carbonic acid which is carried into the soil in rain water. It is the most influential, because of its constancy rather than from any intensity of action which it exerts, but it must be regarded as the natural means for providing plants with silica. The silica being thus detached from its old association, now needs either potash or soda, with which to form a new alliance, and thus become prepared for entering into the plant. In fertile soils these bodies are present, and therefore the passage of rain-water, carrying a supply of carbonic acid into the land, changes the insoluble silicate of alumina into a soluble silicate of potash or soda, and thus gives the growing crop the supply that it needs. If, however, potash and soda are absent, this change does not take place, consequently the proportion of potash or soda in the soil indicates the proportion of silica which can thus become available. Thus, although silica is abundant in all soils, and these receive the carbonic acid which sets the silica free, still the necessity exists for the action of other bodies, which in many cases are very limited in their supply. The addition of potash or soda to such soils would in such cases not only supply potash or soda, but the silica would be carried into circulation at the same time. It is by no means probable that it will ever be necessary to add to the soil supplies of silica, but it is highly probable that provision may have to be made for rendering the silica which exists there available for vegetable growth.

Important as the silicates are to vegetation as food, there is another function which they discharge which is of the deepest importance for maintaining the fertility of the land. We recently laid before our readers an explanation of the important discovery made some few years

since by Professor Way, showing that there exists in some soils a class of salts which he named the double silicates. The action of these double silicates is peculiar, and their influence very important. It has been shown by his researches that these bodies really act as purveyors of ammonia. They have the power of absorbing from the atmosphere the ammonia which exists there, and retaining it until the crop requires it for the purposes of growth. The soil, therefore, becomes a net for arresting ammonia, and it is capable of doing so to an extent very much greater than we can ever equal by any addition of ammonia in the form of manure. If we consider that at the present prices ammonia cannot be purchased, from the cheapest sources, at less than £60 per ton, we must recognize it as a very costly ingredient in our supply of artificial manures. Is it possible that, whilst we are sending to Peru for guano chiefly because it contains an abundant and comparatively cheap supply of ammonia, that our soils can be made to gather large supplies from the atmosphere at a small cost? Of the fact there is no doubt. Let us hope that this discovery may no longer be allowed to slumber, but that it may be brought to bear in such a manner that it shall be of practical value to the farmer.

The action of these double silicates, although very remarkable, is easily explained. When silica is combined with alumina we get a silicate of alumina: when silica is combined with lime we get a silicate of lime. Under certain circumstances these two products combine with each other, and then we get a silicate of alumina and lime, which is one of the double silicates. There are several of these double silicates, for magnesia, soda, and potash can each take the same position as the lime, and form double silicates. The peculiar action of these double silicates is that when exposed to an atmosphere containing ammonia, or if rain-water carries a supply into the soil, the ammonia is immediately laid hold of. Whatever may be the second base which is in combination with the silicate of alumina, whether it be lime, potash, soda, or magnesia, it immediately vacates its position in favour of the ammonia, and thereby this very valuable fertiliser is held captive until the claims of vegetable life call for a supply, and then it is surrendered. It has well been described as the most valuable discovery in relation to manures which chemistry has given us. To be of practical value it must be carried one step further, and some means must be adopted whereby the farmer can at will increase his supply of double silicates; and in proportion as he does so he will be obtaining a supply of ammonia at a cost very far below what he has now to pay for it.

We look upon the presence of silica in artificial manures as valueless and undesirable, and this opinion is doubtless correct. We must not, however, forget that whilst it is impolitic to add to the soil a material which is already existing there in great abundance, it is one of the duties of an artificial manure to supply the agency for rendering the silica of the soil available whenever there is a necessity for it. In this way we shall supply silica by means of manure without adding it in the manure, and this is clearly the wisest policy. To complete the matter we must also adopt measures to increase the supply of the double silicates, then shall we have progressed satisfactorily in the use of artificial manures; but until this has been accomplished we must regard the work as very incomplete.

The employment of salt as a manure has been largely carried out in various parts; in some instances alone, and many more cases in admixture with other fertilizers. We have anything but clear or satisfactory evidence as to its mode of action, for the trials which have been made give us such variable results that at the present time they are conflicting and apparently contradictory. That the contradiction is only apparent cannot for a moment be doubted, for under similar conditions like results must arise. This regularity of action is confirmed by trials of other fertilizers, and there is no reason to believe that salt is any exception to this general rule. We shall briefly notice some of the circumstances which influence the action of salt, and in doing so it will be evident that all our difficulties may be traced to the varied functions which it performs rather than to any uncertainty as to its mode of action.

Salt is required by vegetation as a food, for the mineral matter of almost every cultivated plant which has been examined contains a supply. This may be taken as a proof that salt is necessary for their healthy growth. The chemical examinations which have been made upon the mineral constituents of plants, not only give us proof of its presence, but they also prove that some crops require more abundant supplies than others. The root crops, especially mangold wurzel, and the leguminous crops, beans and peas especially, all require a large supply. The grasses and the corn crops make smaller demands. We have, therefore, a great variation in the quantity of salt which is necessary, according to the kind of crop cultivated.

The variation is still further increased by the district in which land is situated. It has been stated, and with much truth, that the most successful instances of the use of salt as a manure are to be found in inland districts, whilst those applications which have been most unsuccessful have been observed in the neighbourhood of the sea-shore. The explanation of this is self-evident. In the former cases it is clear that in inland situations there is no natural supply of salt, and repeated cultivation consequently exhausts the land of this saline matter. As a natural consequence those crops which need an abundant supply fail to luxuriate, even whilst other plants, content with smaller supplies, for a time continue to yield a satisfactory produce. Ultimately these also fail to get all they require, and then they also decrease in their productiveness. When land has thus lost its productive powers from the exhaustion of the salt, an application of the needful article restores it again. If added moderately it may be enough for those crops which need small supplies, without being enough for other crops needing larger supplies, and thus another variation in the result is observable.

Land which is situated near the sea coast gets such a large natural supply from the sea breezes that the addition of salt as a manure becomes unnecessary, and if applied, little or no good results from its use. It is probable that it gets in this way such an abundant supply that it needs the addition of some other manure of stimulating character to utilize the supply. This we shall see more clearly subsequently, when speaking of the action of salt mixed with other fertilizers. It is, however, a fact that the beneficial results arising from the use of salt depend to a great extent upon the district in which it is used.

Apart from its value as food, salt has other duties to discharge in the soil. Of these the purification or sweetening of the land is probably the function with which all are most familiar. In some cases in which it has been used on grass land much of its influence is exerted upon the herbage, for by adhering mechanically to the leaves cattle and sheep eat it with greater avidity. Thus grass which has been neglected, and would not

otherwise be eaten, is trimmed down close to the ground, and is succeeded by a better herbage. This, however, is due to the relish imparted by the salt, which leads the stock to eat it, and is quite distinct from that sweetening of the land which arises when the salt gets into the soil. This action in the soil arises from the active manner in which salt decomposes decaying organic matter and renders the acids of the soil not only harmless to vegetation, but contributors to its fertility. This is especially observable when salt is used upon old and inferior pasturage which has been broken up. To attain the same result some farmers make a rule of using salt once every four or five years, before the land goes in for the root crops, and there is no doubt it has a very healthy influence upon the soil in addition to its being very welcome to the root crop.

Thus far we have noticed salt as a promoter of fertility, but it has another influence in many instances, and becomes a powerful check to vegetable growth. No satisfactory explanation has as yet been given to account for this result. It is, however, worthy of consideration, because in many instances this action becomes very desirable. We cannot give a better example than is frequently seen in the combined use of salt with nitrate of soda. Upon certain soils the action of nitrate of soda when sown upon a corn crop is too powerful. The growth is as it were over-pressed. If the straw be taken notice of it will be found longer and weaker than usual, and an examination of the ear shows the grains of corn wider apart than usual, as if some one had stretched the ear. Often we also find some grains deficient, as if the sap had over-run them altogether. When this arises it is found that a mixture of salt with nitrate of soda checks this over-growth—stops the excessive growth of straw—strengthens the straw, and secures a more compact and better ear of corn. It is in consequence of this action that nitrate of soda which has been adulterated with common salt gives a better result than a purer nitrate, and the discredit is thrown upon the wrong individual. As a rule, however, farmers prefer making their own additions of salt when such is found necessary.

In the case of land near the sea-coast which becomes freely charged with salt there is frequently observed a great sluggishness of growth. In such an instance the nitrate of soda, or some similar stimulant comes advantageously into play, and gives that impetus to growth which such lands require. Thus, whilst in the former instance the salt became a wholesome corrective of the impetuous growth induced by the nitrate of soda, in the present case the nitrate gives that vigour of growth which the soil freely charged with salt so much needed.

There are other duties which salt has to discharge in the soil which we cannot here notice, but enough has probably been said to explain much of the uncertainty which is supposed to attend its employment as a manure. Under judicious use it is a valuable fertilizer, and it is probable that if its price were ten times as great as it now is we should deem it worthy of more thorough attention than it now receives. The farmer, we know, needs no such stimulus as this. Show him how it is most economically used, and he will gladly adopt it, but so long as he is in comparative ignorance of what he is dealing with in the manures he is using upon his land, so long is it simply impossible for him to come to any correct conclusions as to their relative value.

In a series of articles we have drawn attention to the principles necessarily involved in the composition of artificial manures, and whilst avoiding on the one hand any interference with private interests, we have shown on the other hand that much has to be done before the production of these manures arrives at a

satisfactory position. There is no doubt that most important interests are involved in this manufacture. As a trade, the production of artificial manures has attained a magnitude of which few can form any adequate conception. It is also increasing year by year, and will doubtless assume even greater importance as time rolls on. No stronger reason could possibly be advanced to show the necessity for a fuller consideration of the laws which regulate the economical increase of the fertility of soils, and the removal of those causes of barrenness which are so much on the increase.

In this improvement we are satisfied that the manufacturers of artificial manures will gladly co-operate with their customers. As men guided by sound commercial views, they must feel that the more perfectly they promote the interests of those who deal with them, the better will be the support they will continue to receive. It never pays any one in the long run to sell an unprofitable article, and so generally is this feeling entertained in the trade, that we are satisfied that in the much desired improvement of artificial manures, the hearty co-operation of the trade may be relied upon.

The interests of the farmer are such that he is certain to be a warm supporter of any improvement which will enable him to promote the fertility of the soil at less expense, and with more satisfactory results. The outlay which is made every year for purchased manure is a very heavy charge upon the occupier. It is, however, an unavoidable outlay, unless we fall back into a slower system of farming, but with the present charges upon the land this cannot be done. What is really wanted is such assistance as without increasing the present outlay shall give better results, and allow a wider margin for what is known in commercial circles as profit. Amongst the agricultural classes profits are more frequently talked about than realized, and therefore any improvement calculated to act in this direction will be welcomed.

It appears that neither the makers nor the consumers are in a position to carry out this work alone, but much may be done by a cordial co-operation. As we have previously remarked, one of the first steps towards obtaining anything like sound experience, is to give farmers the opportunity of dealing with manures of a known composition. It may at first appear as if this involved an exposure of trade secrets, but this is by no means a necessary consequence, and even if it were so, we question if it would be a sound policy thus to impede progressive improvements.

One manufacturer may arrive at a certain result by a more economical process than another, but when the result has been arrived at there can be no objection to state what is the strength of the product offered for sale. It would intrude upon the secrets of his trade to inquire how he has arrived at this result, but this is not suggested. The manure sold should be of known composition—say so much ammonia, nitrate, soluble phosphate, insoluble phosphate in an available form, alkaline matter, and salt: then the buyer will be dealing with something tangible and definite, and he will soon appreciate the advantages of this knowledge.

The next step will follow with great ease, for he will soon require facilities for increasing those constituents he needs most, and economising his outlay by not purchasing what he does not require. The consumer will form his own opinion upon the relative influences of the materials he is using, and it will be for the manufacturer to meet that variable demand as it arises. It is as inconsistent to believe that one kind of manure or one definite mixture of manures is to be an economical mode for restoring the fertility of various classes of soil, as to consider that one kind of medicine is to cure all kinds of diseases. We may with great safety predict that when the farmer knows

what materials he is using he will soon detect his friends, and lay out his money in this direction.

The improvements which would thus be introduced into the manufacture of manures would be great, but it cannot be disguised that this progress would be very much expedited if the farmer received the assistance of scientific research to guide him in his field experiments. It has been shown repeatedly in our remarks upon this subject, that there are many intricate and important details yet to be elucidated. It is not too much to say that these will only be brought to yield the greatest practical benefit by the combination of labour which we have pointed out. There ought to be no difficulty in arranging for such a work; let us hope that those who have the opportunity of promoting this important work will do so with energy, perseverance, and skill.

It would have extended these articles to too great a length if we had treated of all the subjects connected with the composition of artificial manures in the manner which they merit. Already we feel that they have extended to an unusual length, but we are fully sensible of the importance of the subject, and of the improvements which are necessary. One point appears to become very evident by this inquiry, and that is, the great importance which will be attached in future improvements to many fertilisers which at the present time are looked upon with comparative indifference. We have got hold of a great truth, "ammonia for corn and phosphate for roots," and we are running it to such an extent that we quite overlook the fact that there are other fertilising elements which may be equally important. We know that a dozen or more ingredients are required for successful growth, and we also know that the limit of fertility is determined by that essential of growth which is least abundant. Surely this is a sufficient reason for extending our observation more thoroughly into details, and for looking upon the entire question in all its magnitude. If we say that in the purchase of artificial manures between five and six millions are expended annually, we are quite within the bounds of fact. This money is paid by a class of men who have no option but to make the outlay, and who carry on their business with a margin of profit upon their capital smaller than is realized in any other industrial occupation. Add to this the further fact that by far the greater portion of this outlay is made for the purchase of materials respecting which we have but a very imperfect knowledge, and it must be evident that the improvement of our artificial manures is a matter of the most vital importance to agriculture, and that is worthy of far greater attention than it has hitherto received.

THE BIRMINGHAM SHORTHORN SHOW.—A second "Exhibition" in Bingley Hall has been arranged for next Spring, under the same impolitic conditions of every animal entered being put up at 20 gu. as the only reserve price, "one of the main objects of this exhibition being to afford an opportunity to intending purchasers to improve their stock at a time when they are best enabled to form a correct opinion of the value of the respective strains of blood exhibited. If at any time during the year 1870 any animal disposed of at the auction shall be known to be upon the premises of the original owner, or shall be exhibited at any show in his name, the Council shall have the power if they think fit to exclude the stock of such person from competition at any future Shorthorn show." And "the Council rely on the honour of Shorthorn breeders to carry out these regulations in their entirety." No doubt the regulations will be carried out as "entirely" as they were last year, when the chief winners were all bought in at figures long above the 20 gu. limit.

ON THE CLAY FORMATIONS OF ENGLAND.

At the last meeting of the Hungerford Farmers' Club, Mr. J. A. Williams in the chair, Mr. H. TAUMPER read the following paper: Following out a similar arrangement to that adopted in my previous paper on the "Limestone Formations," I shall first give you a slight sketch of the principal beds of clay that occur in the fossiliferous strata, of which the crust of our globe is principally composed, together with their geographical distribution in this country; and, secondly, I shall endeavour to point out their importance to agriculturists. In my former paper, I told you that these fossiliferous strata were divided into three great classes—viz., primary, secondary, and tertiary; and of these three, the primary was the most ancient, and the tertiary the most modern. Commencing therefore with the tertiary or most modern, the first clay formation of any extent that we meet with is the London clay. This clay is found immediately beneath the gravel, which generally constitutes the subsoil of the metropolis; it is of great extent, and varies from 300 to 600 feet in thickness. It produces a dark, tough soil, with occasional intermixtures of sands and variegated clays. It contains numerous layers of nodules of hard argillaceous or clayey limestone, traversed by veins of calcareous spar, that radiate from the centre to the circumference, and these nodules are used in large quantities for cement. These concretions or nodules are called septaria, from the appearance of septa or partitions which this character confers, and these septaria generally lie in horizontal lines at unequal distances from each other. It is largely developed in the counties of Essex, Middlesex, and Hants; and also occurs in parts of Herts, Bucks, and Berks; at Bognor and Bracklesham in Sussex, and at the Isle of Sheppey in Kent. At the last named locality especially, large quantities of fossil fruits of the palm tribe, such as are now found in the Molucca and Philippine islands, together with the bones of crocodiles, turtles, and other animals of a tropical character, occur. These fossil fruits might have been drifted into the London basin by currents such as the Gulf stream, which at the present time deposits similar fruits on the west coast of Ireland, which are doubtless brought from the West Indies; but the bones of crocodiles, turtles, &c., seem to imply a very warm, if not a tropical climate, in these parts, at the time the London clay was deposited; and the marine shells found in it, confirm the inference derivable from the plants and reptiles of a high temperature. Beneath the London clay, and immediately above the chalk, we meet with beds of sand, mottled clays, and rolled flint pebbles derived from the chalk, and this formation is called the plastic clay, because its clay is used in some parts, as near Poole in Dorsetshire, for pottery; in fact, the great Staffordshire potteries are supplied with plastic clay from this locality. The principal places where it is developed are Newhaven, in Sussex; Reading, in Berks; and Woolwich, in Kent; but it is largely developed in this neighbourhood, and must therefore be familiar to you all. We next come to the secondary or middle class, and the first clay formation that we meet with is the Weald clay. This clay forms the uppermost bed of the Wealden formation of Surrey, Sussex, and Kent, which occurs immediately beneath the cretaceous or chalk formation. It is of freshwater or fluviatile origin, for in it there is an entire absence of marine fossils, so characteristic of the cretaceous rocks above, as well as of the oolitic strata below; while it contains large numbers of fluviatile shells, together with the bones of terrestrial reptiles, and the trunks and leaves of land plants. It was evidently deposited at the mouth of a great river, like the deltas of the Nile, Ganges, Mississippi, &c. This formation contains the fossil remains of a large herbivorous reptile, called the Iguanodon, because it somewhat resembles the iguanas which now frequent the tropical woods of America and the West Indies; and from these fossil remains the probable length of these saurians is estimated at between 30 and 40 feet. The fossils of the Weald, like those of the London clay, seem to imply a much warmer climate than that now enjoyed in England. Beneath the Wealden we come to the oolitic group, in the upper division of which, below the Portland oolite and sand, we come to the Kimmeridge clay.

This argillaceous deposit consists of a dark bluish and grey clay, which in some places passes into a bituminous shale. It is 300 feet in thickness in some parts, but thins out to a very inconsiderable layer in others, while in the northern counties of England it is altogether wanting. Its name is derived from Kimmeridge, in Dorsetshire, where some of the layers are sufficiently combustible to be used as fuel. It is largely developed in the Isle of Portland, around Hartwell in the vale of Aylesbury (where it abounds in organic remains of great beauty), near Oxford, and in some parts of Wiltshire, where it resembles peat. This clay forms the valley in which the Swindon station and the new town are situated. The middle oolite consists of the limestone called "coral rag" (which was described in my last paper), and the Oxford clay, so called because it is largely developed in the county of that name. It also occurs in some parts of Wiltshire, in the neighbourhood of Chippenham, and occupies the whole of the wide valley around Cricklade. Some very beautiful fossils are found in it in some places, as at Christian Melford, &c., and it is sometimes not less than 500 feet in thickness. The lower division of the oolitic group contains clays and sandstones, called the "cornbrash," passing downwards into an argillaceous limestone called "forest marble." In some places, as at Bradford in Wilts, this limestone is replaced by a mass of clay 60 feet thick, which is called the Bradford clay. There are also beds of fuller's earth near Bath. This lower oolite extends from Yorkshire in the north-east to Dorsetshire in the south-west, and it is largely developed in the counties of Gloucester, Oxford, and Northampton; but it consists principally of limestone formations, which I described in my last paper, and it is only here and there that it contains any clays which are of any extent. Beneath the oolite we have a formation of argillaceous limestone, marl, and clay, called the lias, which some geologists class as part of the oolitic group. In some places, as near Bath, they pass indeed into each other; but the lias can be traced throughout a great part of Europe as a separate and independent group, varying from 500 to 1,000 feet in thickness. It is largely developed in the counties of Dorset, Somerset, Gloucester, Northampton, Warwick, and York; in fact, it extends along the western escarpment of the oolite, from Whithy in Yorkshire to Lyme Regis in Dorsetshire. This formation, like that of the London clay, contains septaria, which are largely used for cement; it also contains the fossil remains of large marine reptiles, for which it is celebrated. These have been termed ichthyosauri and plesiosaurs, and their remains have been found principally in the cliffs at Lyme, Watchett, Westbury, and Whithy. Next to the lias we have beds of sandstones, clays, and shales, containing gypsum and immense beds of rock-salt. This formation is called the "trias": it extends nearly parallel with the western boundary of the lias from the river Tees on the Yorkshire coast, to the Dorsetshire and Devonshire coasts near Lyme Regis, Sidmouth, and Torbay. But the district of which the trias forms the subsoil, is variable in breadth, from the great extension of its western limits. It is largely developed in Worcestershire, Warwickshire, Cheshire, Lancashire, &c. It is the grand repository of rock-salt, produces some of the most fertile pasture lands in the kingdom, and terminates the secondary class of fossiliferous strata. The primary, or most ancient class consists principally of limestones, sandstones, and shales; and as it contains no clay formations, will not come under my notice in the present paper. Having briefly pointed out the geographical distribution of the clay formations of England, I shall now endeavour to treat of their importance to agriculturists; but before doing so, I think it would be advisable to say a few words on the composition and general properties of clay. Clay is a plastic earth consisting of about one-third of alumina to two-thirds of silica, or sand; that is to say, it is really a silicate of alumina. It is derived for the most part from the decomposition of felspathic rocks, which are generally rendered impure by the admixture of oxide of iron, lime, magnesia, &c. It owes its plasticity to the alumina, and ceases to be called clay when the proportion of silica or sand is too great for plasticity.

When iron is present the clay burns red. Tolerably pure clays, though infusible in the furnace, become readily so by the admixture of lime, iron, manganese, &c.: they are very absorbent of water in their dry state, and adhere strongly to the tongue. Ochrey, impure clays, emit a disagreeable earthy smell when breathed upon, and when they contain a sufficient proportion of carbonate of lime to effervesce with acids, they are termed "marls." Potters' clay and pipe clay are pure plastic clays, free from iron, and consequently burning white. Porcelain clay is derived from the decomposition of felspar: it occurs in Cornwall. The London clay I have before said produces a dark tough soil, and where it is properly drained and cultivated, is very good pasture land; it is also good wheat and bean land; and in those districts where it contains an additional admixture of sand, so as to give it loamy character, as in some parts of Middlesex, Essex, &c., it will grow almost anything. The plastic clay is not generally so tractable as the London clay; in many districts it is of a cold, sour nature; but this might be materially altered by means of efficient drainage and chalking or liming. The weald clay, like the plastic, is naturally a very unkind, cold soil, but where it is properly drained and limed, it produces some very good land. A great proportion of the hop plantations of Sussex and Kent belong to this formation; and there are thousands of acres of it in those counties which at the present time are comparatively useless, but which might be rendered very productive if the above-named means were only made available. I have often thought how disappointed foreigners must be who—having heard so much of British agriculture—on coming to England travel by the South Eastern Railway from Folkestone to London; for, on a great part of their journey, they pass through some of the worst-cultivated land in this country, although there are some very highly-cultivated districts in the vicinity. On the Kimmeridge and Oxford clays we have some of the most fertile vales in the kingdom, both as pasture and corn-growing lands. The celebrated vales of Bucks, Berks, Oxford, and Wilts, derive their fertility principally from these clays; but many of these tracts might be very materially improved by efficient draining. It is a painful fact, however, that in many instances, where "God does most, man does least." I have before mentioned that the sandstones, marls, and clays of the triassic group produce some of the most fertile pasture lands in the kingdom. I hope a discussion will ensue from these brief remarks as to the best means of cultivating our clay lands; but it seems to me that the first thing to be done is to get rid of the superfluous water. The second thing, in most instances, is to add chalk or lime; because, as I before told you in my paper on the limestones, it corrects sourness and augments the decomposition of vegetable matter; but without the land is previously drained lime cannot percolate through the soil and perform its proper functions. I also think that it on these clay lands that we shall more particularly find the benefits derivable from steam cultivation. All soils have the power, more or less, of absorbing ammonia from the atmosphere, but clay and peat soils possess this property in a much greater degree than any others; and, therefore, the more porous you can render them—so as to let the air get thoroughly into them—the better; and in proof of this I have seen wonderful effects produced on some of the clay lands of Essex merely by burning a portion of the soil in heaps, spreading it over the fields, and then ploughing it in. This sort of rubble can only act mechanically by rendering the soil more porous and consequently more accessible to the fertilizing effects of the atmosphere. In conclusion, I will only add, that if the large landed proprietors of this kingdom were only to grant their tenants good long leases, and share with them the expense of draining the wet clays, thousands of acres of land might be reclaimed, which at the present time are almost useless; and they would thus not only improve their estates, as well as their own and their tenant's pockets, but they would confer a great and lasting benefit on the country at large.

(Mr. Trumper exhibited a series of fossils from the clay as illustrative of his paper.)

Mr. LANE said the clays of England formed an important tract of land, and in an agricultural point of view possessed more value than was derived from them, containing more potash than any other formation, and potash as was well known was a highly valuable ingredient. The great thing was to get rid of the superfluous water, by draining or chalking, and to allow the air to permeate the soil. One advantage clay pos-

sessed was that it was more difficult to exhaust than any other soil when well cultivated. They might crop and crop as long as they pleased, if it was done in good weather; but it was a very different thing in light porous soils, in which the soluble matter was very likely to be washed out. In some districts a great deal was done by mixing soils, which he (Mr. Lane) strongly advocated.

Mr. KIMBER agreed with the system of "lifting" the land, but did not approve of steam cultivation. He would "lift" it with horses, 5 or 6 inches deep. He thought, if he had a farm for five years only, it would pay him to chalk it the first year. He did not agree with Mr. Trumper if he approved of burning couch and ploughing it in.

Mr. LAWRENCE thought chalking a great benefit to stiff clays, but clays with a chalk subsoil did not require draining. Chalking, however, had wonderfully benefited his crops, and destroyed injurious weeds. A great deal of clay land in that neighbourhood should be drained; some of his land had been drained by a Government loan, and he paid a certain interest on it, the amount being chargeable on the land. His landlord had effected former drainage.

Mr. KIMBER said in the Woodlands they had nowhere to drain it to. (A voice: Drain it into Lamborne.)

The CHAIRMAN said the cultivation of clay land some years ago was a very expensive process, and was therefore greatly shunned. The land by the constant treading of three horses at length in the furrow, when ploughed, was completely puddled. Clays could be drained in a hilly country, as he could prove by an example on his own farm. He had a field called Middle Pond, he supposed because there was a pond in the middle, being the lowest part of the field. He dug a pit for chalk, and before it fell in put a fire pole down, and cut a drain from the pond into the pit. The pond disappeared, and there had been no water there since. He greatly advocated steam cultivation, because it remedied the effect of centuries of treading, and loosened the ground, thus admitting the sunshine and the air. The chairman concluded by mixing common vinegar and chalk, as an experiment proving the effect of carbonate of lime on acid.

Mr. TRUMPER much agreed with Mr. Lane as to the desirability of mixing soils, and the expense would be, he thought, comparatively nothing, for they had men and horses standing about many frosty days when they might be employed carting chalk on to clay or clay on to chalk. But the tenant farmer had very little encouragement to improve his land under the present system of yearly tenancies with six months' notice to quit. If he improved his land, more rent was put upon it. The arguments which were brought forward for the improvement of the land system in Ireland applied equally as forcible in England. He approved of steam cultivation because it did not turn up the rank soil at the bottom which it would take years of exposure to fertilize, but loosened the ground 10 or 12 inches deep, and exposed it to the action of the atmosphere. Mr. Kimber had misunderstood him as to burning couch; he did not approve of it, but thought there was no greater mistake than to burn couch for the ashes; they might let it rot, but many valuable properties were lost by burning. He advocated that the rough clods of a clay field should be stubbed up and burnt into a sort of brick rubble, and carted on the land. It rendered the land more porous and more accessible to the atmosphere. Chalk was better for clay than caustic lime, as lime had to be re-converted into carbonate of lime by exposure before it was of any use, the only advantage was that lime was doubly as portable. Hard limestone rock would never act at all till it was burnt, and then, when re-converted into carbonate of lime by the atmosphere, it became friable and fit to act readily on the soil. Having argued in favour of Government loans, Mr. Trumper said, though the Chairman's experiment was perfectly correct, when they described clay as sour land, it was not because it actually contained acid, but protoxide of iron, a substance poisonous to vegetable life, which decomposition converted into peroxide of iron.

The meeting concluded with votes of thanks to the Chairman and Mr. Trumper.

THE ROYAL AGRICULTURAL SOCIETY OF IRELAND.—At a Meeting of the Council it was resolved to hold the Show in 1870 at Ballinasloe, and not in Dublin, as previously agreed to.

ON SEEDS AND GRASS LANDS.

At a meeting of the Kendal Farmers' Club, Mr. KEY, of Casterton, read the following paper on Grass Seeds and Permanent Pasture: In introducing the subject I shall merely give you an outline of my own practice, based upon thirty-three years' experience. However people might differ in the last generation as to the most remunerative modes of farming, a great majority of the practical farmers of the present day will agree with me when I say that were one-half of the arable land in this county properly laid down for permanent pasture it would yield a more profitable return to the occupier. When I say this I wish it to be perfectly understood that I do not include moss land, knowing that it is more suitable for ploughing than for grazing. But how often do we hear farmers say, "I am obliged to plough my land, it won't graze!" Whenever I hear of land that won't graze I attribute the failing to the management of it more than to any inherent disqualification in the soil itself. I go every three months into a part of Yorkshire where nothing but the plough is believed in, and where they would plough up every acre of grass land upon their farms if allowed to do so, and even there I have still found some isolated verdant pastures standing out, as it were, in bold relief, each like an oasis in the desert, and these solitary instances are generally good specimens of rich permanent pasture. Yet the people still persist in telling you that their land won't graze, in spite of the ocular demonstration they have to the contrary in the samples before them, which are subject to the same atmospheric and geological laws as their ploughed land. One common cause of failure in sowing down land to pasture is an improper selection of seeds. Many farmers never think of sowing more than two or three different varieties. A bushel of rye-grass and from 7 lbs. to 10 lbs. of clover used to be, and perhaps still is with many, the general allowance per acre; yet if you will go into an old pasture and take out a sod twelve inches in diameter, you may probably find from eight to sixteen different plants in that small area. Hence, if we take the trouble to sow the seeds of all these different varieties at once, we may naturally expect an earlier formation of thickly-matted park-like sward than if we left that operation for time and the elements to accomplish. Before sowing our seeds it would be as well to examine some old pasture in the neighbourhood, and endeavour to select those grass seeds which seem indigenous to the soil. I will give you a collection which I have used for the last thirty years and upwards with great success generally, and which I hereby denominate the "Quantity of seeds per statute acre for permanent grass:" 6lb. of Italian rye-grass, 6lbs. perennial rye-grass, 3lbs. cocksfoot, 2lbs. timothy, 3lbs. meadow fescue, 1lb. varied-leaved fescue, 1lb. hard fescue, 2lbs. rough-stalked meadow grass, 2lbs. meadow foxtail, 1lb. of crested dog-tail, 1lb. sweet-scented vernal, 3lbs. alsike clover, 2lbs. white clover, 6lbs. cow grass; total, 88½lbs. Some of you may take exception to the small proportion of perennial rye-grass allowed in the mixture, it being a grass so universally sown in large quantities. I grant that it is a most useful plant for a hay crop; but pastures abounding with it are never eaten level, and cattle will not take it so long as there is any other to bite at, and, were it not essential for a thick sward, I would leave it out of the mixture entirely. Italian rye-grass is not permanently useful, inasmuch as it is only a biennial plant; but, as it is a quick grower and a heavy cropper for the first year, it affords shelter to the tender grasses, and fills up the ground until the more tardy growers come to maturity. In the above-named collection you will observe that there are fourteen different varieties, and the cost per acre will be about 24s., more or less. Those who consider this too expensive a dose, I would recommend to ponder the trite axiom, "whatever is worth doing at all is worth doing well." In addition to the two aforesaid reasons for not using Italian or perennial rye-grass to any great extent, I have also another great reason which I shall hereafter explain. Most of you are aware that when a farmer has to go into the market to buy seed-wheat, he is very careful to purchase a sample which is free from darnel, smut, and all other weeds to which a wheat crop is

liable, or in like manner in the selection of any other seed-grain. But when you or I go to purchase our Italian or perennial rye-grass seeds, we cannot detect the difference betwixt what is generally called twitch-grass and either of the aforesaid varieties, and I am sorry to say in too many cases twitch-seed often accompanies those varieties. I say this with the greatest deference to all seed-growers and seed-sellers; I am making no personal observations, neither could I attempt to do so, but I know it from painful experience to be a fact, and to illustrate the aforesaid fact, I once laid down a field of 9a. 2r. 2p. with nearly the aforesaid mixture of seeds for permanent pasture, the only difference being that I used 9lbs. of Italian, and 9lbs. of perennial, being 18lbs. more of each sort to an acre than in the aforesaid mixture. The seeds were sown along with oats after a turnip crop, one-half of the turnips having been consumed on the land by sheep; the land was perfectly clean, and the seeds well tilled with farmyard manure during the following winter after the reaping of the corn crop, and mown once the following summer. After this treatment and great outlay, I very naturally anticipated having a good permanent pasture for years to come; but I regret to say that, after laying two years, twitch-grass made its appearance to a great extent, and was evidently supplanting all other grasses; the consequence was, I was obliged to plough it up again, and a field fuller of twitch-grass I never yet saw; and, after going through a course of thorough cleaning, I ventured to sow it down again with the aforesaid mixture of seeds along with rape, after a corn crop, for permanent pasture, and it is now in pasture, after lying five years, and doing well. It has been twice top-dressed during those five years, once with farmyard manure, and once with 2 cwt. of guano and 2 cwt. of salt to each acre. I could give other instances, if necessary, of a similar kind, on land under the four or five course system of husbandry, which, to my knowledge, was perfectly clean when laid down, but is at present something similar to what mine was after being so unfortunate with the seeds in my first attempt to lay it down. The case, in addition to my own, which I refer to, is about 4 miles from this town, on the high road side leading to Kirby Lonsdale. Most of you here present know how expensive the cultivation of a turnip crop is when land is in such a state as this is in which I have last alluded to; consequently it is most important for us all to know where the Italian or perennial rye-grass seeds were grown which we purchase, being sure to get them off land which is clean and free from twitch-grass, and that they are the seeds from the second crop of hay, which is not so liable to have twitch or other noxious weeds among them as those from the first crop. Some of you may probably say that we may as easily get adulterated small seeds mentioned in the aforesaid mixture as well as the aforesaid grasses: to this I would say that we can detect adulteration in small seeds by merely damping the end of one of our fingers and placing it in the seed bag, in this manner you then can perceive every seed in its own body, and can then judge by the naked eye all the deficiencies amongst those seeds, and we may further pretty nearly ascertain whether they are old or new seeds by bruising them; you will then see whether they are full of juice or not—if not full of juice, you may then suspect that they are old seeds and not so likely to germinate as quickly as those which are full of juice. Another common cause of failure is the want of top dressing after the young grasses have in some measure exhausted themselves. If a field is well seeded, clean, and full of heart, it will graze well for a few years, and then it begins to fall off for want of stimulant. At this stage the general cry is, "Oh, it is done! I knew it would not graze more than three or four years!" And then it is again ploughed up. Now, suppose we had been ploughing this field for corn crops, we would have applied a dressing of manure to every alternate crop at the very least; yet, we imagine it ought to graze from year to year without any top-dressing whatever, forgetful that the milk, beef, mutton, wool, and other produce which has been sold off that field must have

exhausted the soil, and rendered it poor in consequence. The question of sowing-down with or without a white crop, should, in a great measure, be regulated by the domestic economy of the farm. When properly managed, I have no objection to sow-down with a white crop; we can then better afford to give the seeds a top-dressing after the corn crop comes off. The kind of white crop to sow for this purpose has hitherto been a moot question with practical men. Some advocate oats, others barley; but I should prefer the latter, not sowing the barley too rank with seed—say 75 qts. to an acre. By doing this the barley is not so apt to break down and smother the young seeds. I should harrow the barley well in, and make the surface as even as possible for the sowing of the grass seeds, which I would harrow-in with a light harrow and then roll, thus retaining the moisture and getting the seed embedded safely in a fine fresh soil, secure from the dangers incident to this variable climate—taking great care to have all these things done when the land is dry and in good order. If sown with a white crop, great care should be taken in cutting the grain not to cut it too low, so as to injure the young grasses. It has been a common custom of late years in some localities, to sow down with rape and seeds without a corn crop for permanent pasture, and consume the rape on the land by sheep. If intended for permanent pasture, I should prefer sowing a little rye along with the aforesaid mixture of seeds in preference to rape, inasmuch as the roots of the rape plant are so long and fibrous that they take great hold of the land, and a little rye will afford sufficient shelter for the young plants and enable them to develop themselves more evenly and form a better surface, which is indispensable. If this course was pursued, I should prefer not sowing the seed and rye until the latter end of July, thus evading all annual weeds as much as possible, to which the land is liable, which are apt to take the lead and choke the young seeds. Neither would I have them too much eaten by sheep, or any other kind of stock, the first winter. I would also roll the land two or three times at different intervals during the winter and spring, when the land

is in order, with a heavy roller, so as to compress the land and keep the seeds as much as possible from being thrown out by frosty nights and sunny days, which are very apt to do so. Great care should be taken in sowing the seeds evenly so that not an inch of ground be missed, otherwise the unsowed portion will disfigure the pasture for years to come, notwithstanding any after-seeding we may apply. I would then let the seeds remain unmolested until they flower and seed, but not until they ripen. I have an idea that grasses, like many other plants, feed as much from the atmosphere as from the earth; and if we take away the leaf before it arrives at a certain stage of development, we deprive the plant of one of the chief sources from which it derives its nourishment, and a weakened and stunted growth is the result. Hence, I should prefer mowing the first year in preference to grazing with sheep, as they eat so close that they are apt to injure the roots of the plants before they get perfectly established; then, I should give the land a good top-dressing with farmyard manure, and, after that, I would give it a hand tillage, consisting of two cwt. of Peruvian guano and two cwt. of salt, mixed together, to each statute acre, every three years—the salt acts as a deodorizer, and fixes the ammonia of the guano. This course pursued, I feel confident that it would soon repay the farmer, and enable him to have a good park-like sward on his pasture for many years. I have hitherto spoken of seeds for permanent pasture only; but were I sowing down for alternate husbandry under the five-course system, for that purpose I would use a somewhat different and less expensive mixture, the following list will form an ample seeding for one statute acre, namely, 6 lbs. of Italian rye-grass, 6 lbs. perennial rye-grass, 2 lbs. of cocks-foot, 2 lbs. timothy, 3 lbs. alsike clover, 2 lbs. red clover, 2 lbs. white clover, 2 lbs. cow-grass, 1 lb. sheeps-paralely; total, 26 lbs. I may also state, that any land sown down for permanent pasture or alternate husbandry should be in rich condition and full of tillage before the seeds are sown; this is also indispensable to procure a good permanent pasture or even a pasture for alternate husbandry

ABINGDON FAT CATTLE SHOW.

The annual show was held on November 22. Owing to the foot-and-mouth disease and other circumstances, the entries were not numerous. Mr. H. Betteridge exhibited a Hereford Ox, and Col. Loyd-Lindsay a Shorthorn cow, both of which gained first prizes and silver cups. In the sheep-classes, Mr. S. Drace, Mr. G. Wallis, and Col. Loyd-Lindsay were successful exhibitors; while Mr. R. Aldworth carried off Col. Loyd-Lindsay's cup for the best pig in the yard; and Mr. J. Beezley gained a prize for a hunter. In the root department there was more competition than in the other classes; but Col. Loyd-Lindsay took the lion's share of the prizes.

JUDGES:

Cattle.—Franklin, Ascott, Wallingford; A. Edmunds, Longworth; and B. Castle, Charlton, Wantage.
Horses.—T. Theobald, C. P. Duffield, and J. S. Bowles.
Roots.—J. Litchfield, Kingston; T. N. Dewe, Drayton; and R. Pyke, Lyford.
Carn.—J. Weaving, Oxford; and C. Cox, Abingdon.

CATTLE.

First prize of £5 for the best fat ox, H. Betteridge, Haney; second, Col. Loyd-Lindsay, Lockinge Park.

First prize of £5 for the best steer under 8 years and 3 months old, H. Betteridge; second, Col. Loyd-Lindsay.

Prize of £5 for the best fat cow, Col. Loyd-Lindsay.

First prize of £5 for the best two heifers in calf, under 3 years of age, W. Curtis, Fernham; second, W. Curtis.

Prize of £5 5s. for the best beast shown in Class 1 or 2, H. Betteridge.

Prize of £5 5s. for the best beast shown in Class 3 or 4, Col. Loyd-Lindsay.

Prize of £5 5s. for the best two heifers in Class 5, W. Curtis.

SHEEP.

First prize of £3 for the best pen of three fat half-bred wether sheep under 23 months old, S. Drace, Eynaham; second, Col. Loyd-Lindsay.

First prize of £3 for the best pen of three fat short-woolled wether sheep under 23 months old, Sir W. Throckmorton, Buckland; second, Col. Loyd-Lindsay.

First prize of £3 for the best pen of three fat ewes, G. Wallis, Shifford; second, G. Wallis.

Prize of £5 5s. for the best pen of sheep in any class, Sir W. Throckmorton.

PIGS.

First prize of £3 for the best pen of three fat pigs of one litter under nine months old, W. Graham, Wootton; second, G. B. Morland, Abingdon.

First prize of £3 for the best fat pig under 14 months old, R. Aldworth, Hagburn; second, Col. Loyd-Lindsay.

A silver cup for the best pig in the show, R. Aldworth.

HORSES.

Prize of £10 10s. for the best four years old hunter, J. Beezley.

Prize of £5 5s. for the best cart colt under three years old, J. Phillips, Ardington.

ROOTS.

First prize of £3 for the best 25 untrimmed roots of Swedish turnips, grown on a piece not less than five acres, Col. Loyd-Lindsay; second, W. Graham.

First prize of £3 for the best 25 untrimmed root of mangold wurzel, grown on a piece of not less than two acres, Col. Loyd-Lindsay; second, W. M. Tagg, Goosey.

First prize of £3 for the best collection of roots, not less than 10 each, field culture, not less than four sorts, Col. Loyd-Lindsay; second, R. Aldworth.

CORN.

First prize of £3, for the best five quarters of wheat, one bushel in unmarked bag to be pitched, T. Latham, Little Wittenham; second, Col. Loyd-Lindsay.

First prize of £3, for the best five quarters of barley, one bushel to be pitched, R. Aldworth; second, W. Graham.

Best 19 roots of mangold wurzel, R. Aldworth.

Best 19 roots of long ditto, W. M. Tagg.

Best 12 roots of swedes, R. H. Betteridge.

Best 12 roots of turnips, R. Aldworth.

A dinner followed, over which Colonel Loyd-Lindsay, M.P., presided, Mr. W. Aldworth being vice-chairman.

THE BIRMINGHAM AND MIDLAND COUNTIES CATTLE SHOW.

At the first blush, the foot-and-mouth disease should have much to answer for, as its effects may be tested by so short a show in the Midlands. The entries, however, were not only numerically small, but individually moderate. Many of our most famous exhibitors made no sign, as Mr. M'Combie, for one, did not sent a beast; while something like accident prevented any appearance from other well-known homesteads, either here or further on. Mr. Lynn's prize heifer, Aurora, was ill at home with a surfeit; Mr. Foljambe's Cherry Blossom, who was getting as ripe as a cherry, died very suddenly a few days since; and a Devon steer, of Mr. Smith's, was set fire to in his box on the way up from Exeter, and never came before the judges. Then, Mr. Stratton kept anything he might have in this way at home at Chippenham, or back for London; and hence it happened that nothing so very extraordinary was to be encountered even in the Shorthorn classes. Taking them right through, the Herefords have seldom offered so poor a front; nor were the Scotch cattle by any means equal to their pristine form. Of Devons, on the contrary, there was by comparison a large and good show, backed by one or two clever Crosses; but we doubt much if there were really a GOLD-MEDAL animal in Bingley Hall. In fact, the beasts were so evenly indifferent, that another set of judges might reasonably enough reverse many of the decisions; and we certainly do not expect to see the Birmingham lead very strictly followed in London.

Beginning at the beginning, Mr. Heath again had the best of all the Herefords in a four-year-old ox, but this is only half a good one; being very handsome forward, with a fine head and kindly look, as well as a great broad back. But he is spoiled by his terribly mean drooping quarter, and is a very ungainly animal when brought out. The second best Hereford ox is as plain a beast as ever was exhibited, with little but his size and touch in his favour; and we altogether prefer the third prize, the best of all on Monday at Abingdon, where he was shown by Mr. Bettridge, although bred by Mr. Evans, of Swanstone. This is a pretty straight stylish ox, of fine quality, if rather out-sized, the more especially when standing side by side with Mr. Ridgley's six-year-old monster, who fairly towered over everything in the class. This included a very middling specimen from Chadnor Court, and although in it and the younger class there were such names as those of Mr. Pike, Mr. Price, and Mr. Pitt to be seen there was not a really crack Hereford steer in the whole line of them. The two cows sent were so bad that the judges, and even then on something like compulsion, would only award the second and third prizes, utterly refusing to honour anything with a first. On the other hand, Mr. Garrett's best heifer was a very taking one, and to our thinking the best of all the Herefords; being neat, round, and deep, with a nice head and good character, as a long way the first of her class, which was otherwise moderate enough. The Hampton Violet is a podgy creature, with no very visible shoulder, at least where it should be, and standing very in behind; while her Majesty could only have taken the third prize as the best of a very bad remainder. In four classes there were twenty-three entries of Herefords; one prize was altogether withheld, and not a single commendation was appended to those actually awarded. This is sufficiently significant of the strength to be found in this section of the show.

The Shorthorns were in every way better; but here, again, there were no commendations, as the merit, more particularly amongst the oxen and steers, was mainly confined to the first and second of the classes. Amongst the older beasts there was nothing very particular, as not much to choose between Colonel Lindsay's steer and Mr. Rowland Wood's ox. Indeed, they have now beaten each other in turn, Mr. Sanday, at Northampton, in the summer, giving the Clapton beast a prize, and merely commending the Colonel's entry; whereas at Birmingham Mr. Sanday must have been mainly instrumental in placing the Berkshire above the Northamptonshire specimen. In the interim Mr. Wood's animal certainly seems to have gone on the better of the two, and Colonel Lindsay's was beaten at Abingdon by Mr. Bettridge's ox, the third of his class here. This makes the form very moderate; and certainly the first prize Shorthorn is anything but a good beast. He is high, plain, and patchy, with a head showing little or no Shorthorn breed about it, and as, with the exception of Mr. Wood's entry, the others were no doubt worse, this was a very poor class.

The first and second of a small entry of steers did much more for the credit of the breed, and these are, no question, both superior, if not quite first-class animals. Mr. Rowland Wood's steer we first met at Northampton in July, where we spoke of him as "a capital red beast, which his owner had picked up at Oakham last Christmas, and that for handsome looks and level feeding was surely the best of all the fat animals." Little Wonder, for he has a name of his own, went again to Oakham last week, where he not only took the first prize of his class against a very smart steer of Mr. Pulver's that will be kept on for another year, but also the Uppingham School medal and extra premium of 25 sovereigns, as the best of all the fat beasts. But the judges stood alone here, that is as to "the best of all," public opinion at Oakham going for Mr. Willis' Rose of Lucknow, the gold medal cow at Birmingham last year; now, at seven years old, said to be as level as ever, and five inches more in the girth than she was last season. Having already made her appearance in both Bingley and the Islington Halls, the old Rose will next show at York. Still, however well she may have looked at Oakham, there is no doubt but that her conqueror, Little Wonder, has gone on equally well. He is so true and straight in his outline, that the editors of *Herd Books* might point to him in some proof of the fidelity of their very amusing illustrations. He is just a trifle high in the setting on of his tail, but otherwise he is as level a beast as ever was seen; while he has plenty of style, is very deep, and for his age, at under three years, certainly a wonder in his way, if perhaps only a little one. Nevertheless, the Birmingham judges declared that they found his superior in an older steer of Lord Aylesford's; and a very showy beast this is, with more grandeur than the red, a fine quality coat, a beautiful broad back, and so on. But he is not so thoroughly true as the other; his head is badly set on, and he is not so well covered about his shoulders. However, all the Judges held to the light roan very determinedly, for they made him the best of his class, the best Shorthorn bred and fed by an exhibitor, the best of all the Shorthorns, the best of all the oxen and steers, and the best animal in the yard. At the utmost he is the best of a bad year, not that we believe he can be the 100 guineas

winner in London, even if Little Wonder should not beat him when they meet again. A white son of the white Costa was third, but in point of fact, nowhere, in comparison with the other two, and the only class ran up to four or five.

There travelled up from Newcastle-upon-Tyne a certain Princess of Yetholm, bringing with her a very high repute, which she has quite maintained in the Midlands. She is a very neat, not large cow, nicely fed, fashionable in her appearance, and kindly in her touch, so that she looked to place herself readily enough as the best Shorthorn cow. Some, indeed, went further, and, as "bred and fed" by Sir Walter Trevelyan, would have made her the best on this condition also, and so of course the best of all the Shorthorns, while this would have led on to her being not merely the best of all the females, but the best in the yard. Not but that some of her company kept her in countenance, for the Messrs. Mitchell's Blue Belle is a very sweet almost dainty creature, and what with her pretty lady-like head, her nice long low frame and light bone, would seem yet more an ornament for the herd than a victim to the shambles. She has, of course, been a frequent winner in Scotland; and with the honours still all going North, Mr. Whyte's Windsor's Lilac Flower is more like beef, being very heavy-fleshed, but lacking the style of the other two. Colonel Lindsay's Lady Elgin, the best cow at Abingdon, for the want of competition, claimed no notice here; and, although they kept a cow, as we think, of Mr. Sheldon's, out for some time, nothing came of it. In an entry of half-a-dozen the three prize heifers had all some merit. Col. Townley's Thistledown looked rather unwillingly and overdone, but she is grand either to meet or follow, with a beautiful bosom and broad back; while she has flesh put on wherever it can be, but is somewhat disfigured by a big knee. Two years since Thistledown was a first prize heifer at Aberdeen, where she was purchased for 100 gs., but Culshaw could never get her to breed. Cherry Princess 3rd, from Speke, is a prettier heifer if not so valuable as a butcher's beast; as, if we remember aright, she has been to Birmingham before, where she was bought in at the spring sale; while the Aberdeen sample well sustains the fame they enjoy in these parts for growing Christmas fare.

Well as the Devons show in London, they have for some years made no great stand in Birmingham; but there were this season two really good classes of oxen, that walked up from their stalls with something of the air of race-horses; as assuredly there is no beast shows so much blood as a Devon. Of the first and second in the old class and the first and second in the young class it was anything for choice, so evenly were they matched, and so close was the competition. The best *bred and fed* was assuredly Mr. Hambro's Delcome, a very blood-like three-year-old, all good meat to the hand, and an admirable animal when out; while Mr. Nixey's next best in this lot was very neat and taking, but not so ripe. The judges, however, pronounced the best of all the Devons to be Mr. Farthing's older steer, the second in his class at the Plymouth show last Christmas, and a beast of more breed and quality than the Somerset-Devons always reach to. Then he was firm in his flesh if not so forward as he might be, and Mr. Burton's long, straight, stylish second was almost his equal, if Mr. Hambro's were not the best of the three. But the special Devon judge appeared to have lost his head, for he hung to a great coarse animal, of little or no true Devon character, fed at Hooper's, and this he insisted on being placed third, while the two Shorthorn men were quite willing to take the responsibility of those placed higher in the list. The Stowey herd was altogether in force, for Mr. Farthing claimed the best cow in

Lady, who has fed very nicely, and the best heifer in Miss Laura, a Royal Leicester heifer, that is going all in pieces, and getting so gaudy as to be almost unsightly. Mr. Hitchcock's second prize cow, Pretty, from Mr. Tapp's herd, is a nice lengthy one, quite worthy of her place, but taken as a lot the cow classes would not compare with the oxen, and this is of course just as it should be at a fat cattle show.

There were half-a-dozen Long-horns, amongst which, noticeably enough, Mr. Chapman, of Nuneaton, made no entry; there were two or three Welsh runts; three black polled beasts; and some half-dozen moderate Highlanders. From all these the judges found nothing to dwell over, when they fined down their duties to picking out the best ox. Then the best Hereford was one of the first sent away; even the Devon man never seemed to take a second glance at Mr. Farthing's beast; and the only really formidable opponent to Lord Aylesford's steer turned up in Messrs. Martin's Aberdeen cross. This was a great square upstanding animal of more size rather than majestic appearance; far better forward than the Shorthorn, and at his age a much more valuable beast for the butcher. He was not perfect, nor on an average a gold medal ox; but he would most probably have been in such a show, had not two out of the three Judges been Shorthorn men. In 1868, the Bench was made up of one Shorthorn, one Hereford, and one Devon breeder—a much more wholesome arrangement—and we never remember to have watched awards that proved better. The two-to-one plan did not look to work near so well, the more particularly as the unit did not carry such weight even at his own special business.

With the sheep they held to a better division of duty, making up a Quorum from the Longwool, Shropshire, and Southdown fanciers. But then amongst the sheep there was very little to do. In obedience to the call for early maturity, the old classes of wethers have been removed from the list, and the entries cut down to one-half; as, indeed, we never remember this section of the show to have commanded so little interest. The Leicesters were much as they have been here, and Lord Berners was first again with his sheep, such as they are, but there was not an animal of really fine Leicester type in the entry. There were three pens of Lincolns with three prizes awarded, the first and second lots being very excellent sheep. Sir John Rolt's best Cotswolds were of good character, with the second and third prize pens anything but prize sheep; and there were four entries in all of Cotswolds. The first prize, Oxford Downs, were really good, and the other prizes should have been withheld. There were two pens of Hampshires, both apparently reverting to that hang-dog, ugly expression, for which this sort was once so famous, or infamous, and two prizes were duly awarded. Mr. Overman did not enter any cross-breeds, and so Mr. Nathaniel Stilgoe took the first prize with a Cotswold and Oxfordshire Down mixture—or a mixture of mixtures—while Mr. Zachariah Stilgoe was second, with a long and short wool cross, a much more simple way of putting it. The Oxford mixtures were very cleverly got up, but when you came to examine them, no doubt Mr. Zachariah's sheep were a deal better than Mr. Nathaniel's; although, so far as the value of the experiment went, there was not a pen of these Crosses worth any particular encouragement. The judges commended a whole class of Shropshires, and highly commended one particular pen, which was making the most of it; but then Birmingham is something of a capital for Shropshire flock masters. Lord Chesham's neat "Downy" sheep had again, however, all the best of it, though his second-prize lot were not very "sorty;" while nothing could be greater than the contrast between his Lordship's first and Mr. Nock's

third-best, placed as they were side by side. Mrs. Beach continues to preserve a sheep of very nice useful stamp; and, if people could be content to feed at Christmas time on wool rather than mutton, Lord Wenlock's Yorkshire-Shropshires might soon come into fashion. How is it that they have managed to muddle away all the promise, or something more, my Lord once enjoyed, for sheep and pigs? It may be treason to say so, but, as times go, Colonel Kingscote's Southdowns look a vast deal more like Shropshires; whereas Lord Walsingham never showed sheep of purer Southdown type than he has done this year at Birmingham. The first-prize pen were very pictures of what they should be; so admirably matched, with such nicely-shaded shapely faces, such neat symmetrical frames, and all over of such high breeding and quality. They were not large, certainly; and we were almost sorry to hear that they will go for more size in London. During the last twenty or thirty years, some alloy no doubt has been tried with the Southdown, but this is a mistake; for what we gain in weight we lose in almost every other way. The second-prize Merton pen were not equal to the first, but if there had been a cup for the best entry of any animals in the Hall, the Southdowns would have won it.

The entry of pigs barely reached to that of last year, when there was one of the smallest shows ever seen in Birmingham. Nevertheless, some of the pens were very commendable; and, in the opening class, three capital Berkshires, from Upper Winchendon, fairly beat all the whites—a not very common occurrence when they come together. Her Majesty's had more size, but were neither so neat in appearance, nor so firm in their flesh as Mr. Cartwright's pretty pigs; but, in the next lot, the Royal Windsor did better, not only being the best of their own but class, also the Cup pen as the best of all the young fat pigs. They looked, however, at first to be very closely run by another lot of Berkshires, bred by Mr. Clark at Maidenhead, and very long and handsome, but hardly made up enough for exhibition or well matched, for otherwise they would at least have been second. As it was, the judges took their time in deciding between these and the Stroxton whites which, with good ends, were very light and slack in their middles. Mr. Eden's best old pig was of superlative merit in a very good class, with Mrs. Beech showing a very pretty Dorset, and Mr. Sadler getting third with a deep but coarsish Berkshire; while Mr. Clark was again and deservedly commended for a Berkshire sow bred by Captain Stewart of Gloucester, and Mr. Bantock might have done more had his entry been better finished off. Nearly all these fat pigs were quite up to the average of excellence, and there was another good class of breeding Berkshire where the point of preference rested between the high quality of Mr. Spencer and the true useful character of Mr. Fowler. The Aylesbury are no question the most useful farmer's pigs, but they always go for a finely-bred Berkshire in Bingley Hall—a Warwickshire-Berkshire, so to speak—and although the judges were from other parts, they did not rule against the line laid down for them. The class of large breeding pigs was so generally bad, that it was only after considerable hesitation the prizes were awarded. The Messrs. Howard's pen, with their plain heads and big flap ears, were just passable, and that was all; but how a pig-fancier like Mr. Fisher could show and win with such a wretched pen as he did was a very marvel of generosity on the part of the management, and the judges were ready enough to decry their own handiwork. Of course any further prize in this class was withheld, there being a point at which a line must be drawn. The small breeding pigs, on the contrary, were, so far as the prize pens went, all very good, and from Mr. Lynn's lot downwards honestly deserving of the distinction they gained.

All things considered, the display of roots is quite as good, if not better, than might have been expected. Although the early part of the past season was extremely unfavourable to the crops generally, the copious rains of the late summer, and the open weather of the autumn, seemed to have done much to promote the growth of this description of farm produce. The result is that, notwithstanding the show of roots here is less than usual in extent, it is a full average in respect to the size and quality of the various specimens. There were half-a-dozen competitors for the Cup offered for the best collection. As will be seen on reference to the subjoined list, it was won by Sir William Heathcote, the aggregate weight of whose entry was 303 lbs., the six long mangolds weighing 101 lbs., six globe mangolds 134 lbs., and the swedes 86 lbs. The collection which came nearest to this was that of Mr. Dickinson, from the New Forest, whose long mangolds weighed 121 lbs., his globes 95 lbs., and swedes 60 lbs., making a total of 276 lbs. The swedes were remarkably uniform and symmetrical. The kohlrabi was especially good; the specimens were all of the green globe variety; the first-prize collection being very large and handsome bulbs, weighing 102 lbs. The weight of Col. North's six was 74 lbs. The prize stands of long mangolds weighed 192 lbs. and 169 lbs. respectively; globe and intermediate mangolds 119 lbs. and 98 lbs. The first-prize swedes of Mr. Moore (Bangholm) weighed 102 lbs., and those of the Duke of Portland 102 lbs. The class as a whole is very good as respects both size and weight. Of the common turnips the yellow-fleshed kinds were decidedly the best. The carrots were not plentiful, but smooth and handsome examples. The ox cabbage are meritorious, being large and good in quality. The first prize stand weighed 69 lbs., 67 lbs., and 60 lbs. respectively—total 196 lbs. The three which received second honours weighed 58 lbs., 60 lbs., and 58 lbs.—total 176 lbs. The show of potatoes is not large, which may be accounted for by the fact that several other exhibitions are being held about this time. Many good dishes, however, have been brought together, there being no vegetable which has received greater attention or in which greater improvement is manifested than the potato; the red Regents and Paterson's Victoria being well represented.

There is only a very limited display of corn, but there is not an indifferent specimen to be found. The white wheat is remarkably good. Of red there are only three lots entered, but they were considered good enough to deserve the award of both the prizes offered, which were given to good samples of the Nursery kind. The barley, oats, beans, and peas are uniformly excellent.

The Birmingham Meeting is still pre-eminent for its poultry. All the varieties are as usual very fully represented. The following are the weights of the principal prize pens of ducks, geese, and turkeys: White Aylesbury drake and one duck, first prize, 17 lbs. 12 oz.; second, 17 lbs. 7 oz.; third, 17 lbs. 2 oz.; fourth, 17 lbs. Brown drake and one duck, first prize, 16 lbs. 18 oz.; second, 17 lbs. 12 oz.; third, 17 lbs. 12 oz.; fourth, 17 lbs. 13 oz.; fifth, 16 lbs. 6 oz.; sixth, 16 lbs. 6 oz. Geese, grey and mottled, birds above a year-old, first prize, 57 lbs. 14 oz.; second, 53 lbs. 8 oz.; ditto, birds of 1869, first prize, 48 lbs. 12 oz.; second, 46 lbs. 4 oz.; Turkeys, cocks exceeding a year old, first prize, 34 lbs. 12 oz.; second, 32 lbs. 2 oz.; and a very highly commended pen, 29 lbs. 12 oz.; ditto hatched in 1869, first prize, 33 lbs. 12 oz.; second, 23 lbs. 8 oz.; highly commended, 23 lbs. 2 oz. Two turkey hens over a year old, first prize, 37 lbs. 4 oz.; second, 32 lbs. 4 oz.; highly commended, 23 lbs. 12 oz. Two turkey hens hatched in 1869, first prize, 23 lbs. 2 oz.; second, 27 lbs. 12 oz.

PRIZE LIST.

CATTLE.

JUDGES.—H. W. Keary, Bridgnorth.

William Sanday, Kettlewell-on-Trent, Nottingham.
John Thompson, Badminton, Chippingham.

HEREFORDS.

OXEN OR STEERS.—First prize, £15, and extra prize of £20, for the best Hereford, William Heath, Ludham Hall, Norwich; second, £10, Thomas Dew, Almley, Herefordshire; third, £5, Henry Bettridge, East Hanney, Wantage, Berks; reserved, Aaron Pike, Mitton, near Tewkesbury.

STEERS.—First prize, £15, John Price, Court House, Pembridge; second, £10, Henry Bettridge, East Hanney, Wantage, Berks; third, £5, John Williams, Saint Mary's Farm, Kingsland, Herefordshire.

Cows.—First prize withheld; second, £10, William George Senty, Old Saffron Court, near Hereford; third, £5, Joseph Craddock, Easington, Northleach, Gloucestershire.

HEIFERS.—First prize, £15, and silver medal as breeder, Thomas Garrett, Compton Scorpion; second, £10, John Hungerford Arkwright, Hampton Court, Leominster, Herefordshire; third, £5, her Majesty the Queen, Windsor Castle.

SHORTHORNS.

OXEN OR STEERS.—First prize, £15, Colonel Lloyd-Lindsay, M.P. Lockinge Park, Wantage, Berks; second, £10, Rowland Wood, Clapton, near Thrapston, Northamptonshire; third, £5, Marquis of Anglesey, Beauchamp, Rutland.

STEERS.—First prize, £15, and silver medal as breeder; extra prize of £20 for best Shorthorn, and extra of £15 for best Shorthorn bred and fed by exhibitor; President's Cup, value £25, for best ox or steer of any breed or age, bred and fed by the exhibitor; extra of 25 guineas as best animal in the cattle classes, and £20 as the best ox or steer of any breed or age, selected from all the classes.—The Earl of Aylesford, Packington Hall, Coventry; second, £10, Rowland Wood, Clapton, near Thrapston, Northamptonshire; third, £5, John Chyden, Littlebury, near Saffron Walden, Essex.

Cows.—First prize £15, and silver medal as breeder, extra £20 for the best cow or heifer of any breed or age, selected from all classes, Sir Walter Calverly Trevelyan, Wallington, Newcastle-upon-Tyne; second £10, Messrs. A. and A. Mitchell, Alton, Chackmannan; third £5, James Whyte, Clinterty, Aberdeen.

HEIFERS.—First prize £15, Col. Chas. Towneley, Towneley, near Burnley; second £10, Thos. Atherton, Chapel House, Spate; third £5, James Reid, Graystone, Alford, Aberdeenshire. Reserved: William Tidy, Middleton, Tamworth.

DEVONS.

OXEN OR STEERS.—First prize £15, and extra £20 for best Devon, Walter Farthing, Stowey Court, Bridgwater, Somerset; second £10, Richard Burton, Place Barton, Broadclyst, Devon; third £5, Wm. Smith, Hoopers, Exeter. Commended: Chas. Gibbs, Bishops Lydeard; William George Nixey, Upton Court Farm, Slough, Bucks.

STEERS.—First prize £15, and silver medal as breeder, and extra £10 as best Devon, bred and fed by the exhibitor, C. Hambro, Milton Abbey, Blandford, Dorset; second £10, W. Geo. Nixey, Upton Court Farm, Sough, Bucks; third £5, Chas. Gibbs, Bishops Lydeard.

Cows.—First prize £15, Walter Farthing, Stowey Court, Bridgwater, Somerset; second £10, John Hitchcock, Broomhouse, South Molton, Devon; third £5, William Smith, Hoopers, Exeter.

HEIFERS.—First prize £15, and silver medal as breeder, Walter Farthing, Stowey Court; second £10, W. Geo. Nixey, Upton Court Farm; third, William Smith, Hoopers.

LONGHORNS.

OXEN OR STEERS.—First prize £10, and silver medal as breeder, Joseph Holland Barbary, The Chase, Kenilworth; second £5, Sir John Harpur Crewe, Calke Abbey, Derbyshire.

Cows or Heifers.—First £10, and silver medal as breeder, W. T. Cox, Spondon Hall, Derby; second £5, John Godfrey, Wigston Parva, Hinckley.

SCOTCH BREEDS.

POLLED OXEN OR STEERS.—First prize £15, and silver medal as breeder, and extra 10 guineas for best Scot bred by the exhibitor, and £20 for the best Scot, James Stephen, Conglass, Inverurie, Aberdeenshire; second £10, Andrew Longmore, Linkfield, Rattie, Banffshire.

WEST HIGHLAND OXEN OR STEERS.—First prize £15, Capt. Gunter, The Grange, Wetherby, Yorkshire; second £10, Messrs. J. & W. Martin, Aberdeen; third £5 Geo. Lawson, Clynelish, Broma, Sutherlandshire, N. B.

SCOTCH Cows or HEIFERS.—First prize £15, Sir Walter Calverly Trevelyan, Wallington, Newcastle-upon-Tyne, Northumberland; second £5, James Reid, Graystone, Alford, Aberdeenshire.

WELSH BREEDS.

OXEN OR STEERS.—First prize £15, Capt. Henry Platt, Gorrindog; second, £5, Capt. Henry Platt.

OTHER PURE BREEDS AND CROSS-BRED ANIMALS.

FAT OXEN OR STEERS.—First prize £15, Messrs. J. & W. Martin, Aberdeen; second £10, John P. M'Pherson, Muirtown, Kinloss, Forres, Elgin; third £5, Aaron Pike, Milton, near Tewkesbury, Gloucestershire.

FAT Cows or HEIFERS.—First prize 15, and silver medal as breeder, Harry L. L. Morrison, Blair Guise, Whitehouse, Aberdeenshire; second £10, Aaron Pike, Milton, Tewkesbury; third £5, Gilbert Mitchell, Meikel Haddo, Newburgh by Aberdeen. Commended: Alexander Cowie, Crombley Bank, Ellen, Aberdeenshire.

EXTRA CLASSES.

For animals not qualified to compete in any of the preceding classes.

OXEN OR STEERS.—[No entry].

Cows or HEIFERS.—Prize, £5, and silver medal as breeder, John Walker, Westfield, Holmer, Hereford [only entry].

SHEEP.

JUDGES.—C. Clarke, Scoopwick, Lincoln.

H. Luger, Ingham, Bury St. Edmunds.

Thomas Mansell, Ercall Park, Wellington, Salop.

LEICESTERS.

Three fat wethers, not exceeding 22 months old.—First prize, £15, and silver medal as breeder, an extra prize of £10, Lord Berners, Keythorpe Hall, Leicester; second, £10, William Browne, Higigate, Holme-on-Spalding-Moor, Yorkshire; third, £5, William Browne, Higigate. Commended: Executors of Francis Jordan, Eastburne, Driffield, Yorkshire.

LINCOLNS.

Three fat wethers not exceeding 22 months old.—First prize, £15, silver medal as breeder, and extra prize of £10, John Byron, Kirby Green, Sleaford, Lincolnshire; second, £10, T. R. Casswell, Quadring, Spalding; third, £5, Richard Newcomb Morley, Leadnam, Grantham.

COTSWOLDS.

Three fat wethers not exceeding 22 months old.—First prize, £15, silver medal as breeder, and extra prize of £10, Sir John Rolfe, Osleworth Park, Wotton-under-Edge; second, £10, Richard Hall, Great Barford, Deddington, Oxon; third, £5, John Baldwin, Luddington, Stratford-on-Avon.

SOUTHDOWNS.

Three fat wethers not exceeding 22 months old.—First prize, £15, silver medal as breeder, and extra prize of 10 gu., Lord Walsingham, Merton Hall, Thetford, Norfolk; second, £10, Lord Walsingham; third, £5, Lord Sondes, Elmham Hall, Thetford, Norfolk. Commended, Lord Walsingham.

SHROPSHIRE.

Three fat wethers not exceeding 22 months old.—First prize, £15, silver medal as breeder, and extra of 10 gu. for best pen of 3 Shropshires, Lord Cheaham, Latimer, Chesham, Bucks; second, £10, Lord Cheaham; third, £5, Thos. Nook, Sutton Maddock, Shifnal. Highly commended: William Yates, Brindle House, Shifnal, Salop. Commended: Henry Matthews, Montford, near Shrewsbury. The class commended.

Three fat wethers, exceeding 22 but not exceeding 34 months old.—Prize of 10 gu., as best pen of 3 two-shear Shropshire wethers, and silver medal as breeder, Mrs. Beach, The Hattons, Brewood, Penkridge, Staffordshire.

OXFORDSHIRES.

Three fat wethers, not exceeding 22 months old.—First prize, £15, and silver medal as breeder, and extra of £10 for best pen of Oxfordshires, Alfred Rogers, Bromham, near Bedford; second, £10, Zachariah W. Stilgoe, Adderbury Grounds, Oxon; third, £5, Nathaniel Stilgoe, the Manor Farm, Adderbury, Oxon.

SHEEP NOT QUALIFIED TO COMPETE IN ANY OTHER CLASS.

Three fat wethers, not exceeding 22 months old.—First prize, £15, and silver medal as breeder, Col. Loyd-Lindsay, Lockinge Park, Wantage, Berks; second, £5, John Walker, Bearwood, Wokingham, Berks. [both hens Hampshire].

CROSS BREEDS.

Three fat wethers, not exceeding 22 months old.—First prize, £15, and silver medal as breeder, Nathaniel Stilgoe, the Manor Farm, Adderbury, Banbury; second, £5, Zachariah W. Stilgoe, Adderbury Grounds, Oxon.

FAT PIGS.

JUDGES.—A. F. M. Druce, Burghfield, Reading.
E. Little, Lanhill, Chippenharn.

Three fat pigs of one litter, not exceeding 10 months old.—First prize, £10, and silver medal as breeder, John Treadwell, Upper Winchendon, Aylesbury; second, £5, Thomas Lealie Melville Cartwright, Melville, Ladybank, and Newbottle, orthamptonshire; third, £3, the Queen, Windsor Castle.

Three fat pigs of one litter, not exceeding 15 months old.—First prize, £10, and silver medal as breeder, and extra of 5 guineas, as best pen of three fat pigs, the Queen, Windsor Castle; second, £5, John Lynn, Church Farm, Stroxtan, Grantham; third, £3, Joseph H. Clark, Altwood, Maidenhead, Berks.

Fat pig exceeding 15 months old.—First prize, £6, and silver medal as breeder, Peter Eden, Cross-lane, Salford, Manchester; second, £4, Mrs. Beach, The Hattons, Brewood, Penkridge, Staffordshire; third, £2, W. J. Sadler, Bentharn, Calcutt, Cricklade. Highly commended: Thomas Bantock, Merridale House, Wolverhampton; Joseph H. Clark, Altwood, Maidenhead.

BREEDING PIGS.

BERKSHIRES.

Five pigs of one litter, exceeding 3 and not exceeding 6 months old.—First prize, £10, and silver medal as breeder, and extra of 5 guineas, for best pen of Berkshires, John Spencer, Villiers Hill, Kemilworth; second, £5, Richard Fowler, Broughton Farm, Aylesbury; third, £3, Captain Stewart, Saint Bridge House, Gloucester.

PIGS OF OTHER LARGE BREEDS.

Five pigs of one litter, exceeding 3 and not exceeding 6 months old.—First prize £10, and silver medal as breeder, James and Frederick Howard, Britannia Farm, Bedford; second, £5, John Fisher, Woodhouse, near Cross Hills, Yorkshire.

PIGS OF A SMALL BREED.

Five pigs of one litter, exceeding 3 and not exceeding 6 months old.—First prize, £10, and silver medal as breeder, and extra of 5 guineas, for the best pen of pigs of a small breed, John Lynn, Church Farm, Stroxtan, Grantham; second, £5 Peter Eden, Cross Lane, Salford, Manchester; third, £3, The Queen, Windsor Castle.

REFERENCE FOR THE AGES OF STOCK.—Professor Gamgee, Queen's-road, Baywater, London.

VETERINARY INSPECTOR.—E. Stanley, 35, Ialington, Birmingham.

CORN.

JUDGES.—Edward Davenport, Erdington.

J. Matthews, Edgbaston, Birmingham.

White wheal, sample of one bushel each.—First prize, £2, Col. Lloyd-Lindsay, Stocking Park, Wantage, Berks (Talavera); second, £1, Joseph H. Clark, Altwood, Maidenhead (Chidham); Highly commended: Joseph Greatorex, Stretton, near Burton-on-Trent. Commended: Henry Frampton, Watership, Sidmonton, Newbury, Berks (Chidham).

Wheat, red, samples of one bushel each.—First prize, £2, Thos. Horley, jun., The Fosse, Leamington (Nursery); second, £1, Richard Hall, Great Barford, Deddington, Oxon.

Barley, samples of one bushel each.—First prize, £2, Edward Parrott, Shirburn Farm, Tetworth, Oxon (Hallett's Pedigree); second, £1, Henry Frampton, Watership, Sidmonton, Newbury, Berks (Hallett's Pedigree Chevalier).

Oats, white, samples of one bushel each.—First prize, £2, Joseph Greatorex, Stretton, near Burton-on-Trent; second, £1, Frederick Lythall, The Spittal Farm, Banbury (Australian). Commended: E. Morley, Sapcote, Hinckley, Leicestershire.

Oats, black, samples of one bushel each.—First prize, £2, Frederick Lythall, Spittal Farm, Banbury; second £1, Richard Hall, Great Barford, Deddington, Oxon.

Beans, samples of one bushel each.—First prize, £2, Joseph H. Clark, Altwood, Maidenhead (White Eyes); second, £1, Frederick Lythall, Spittal Farm, Banbury (French Eyes).

Peas, white, samples of one bushel each.—First prize, £2, Joseph H. Clark, Altwood, Maidenhead (Ringwood Marrow); second, £1, Frederick Lythall, Spittal Farm, Banbury (Banbury Prize-taker).

Peas, blue, samples of one bushel each.—First prize, £2, Frederick Lythall, Spittal Farm.

Peas, grey, samples of one bushel each.—First prize, £2, Frederick Lythall (Partridge).

ROOTS.

JUDGES.—Edward Davenport, Erdington.

J. Matthews, Edgbaston, Birmingham.

A silver cup of five guineas, for best collection of Long Mangold Wurzel, Globe Mangold Wurzel, and Swedes, six roots of each to be shown for this prize only.—Sir William Heathcote, Hursley Park, Winchester (Hall's Mangold, and Hall's Imperial Westbury Swede).

Kohl-rabi (six specimens).—First prize, £2, Geo. Fleming, Groundsall Fields, Stone, Staffordshire; second, £1, Colonel North, Wroxton Abbey, near Banbury.

LONG MANGOLD WURZEL, (six specimens).—First prize, £2, and extra of £2 2s. Geo. Baylis, Gayton Farm, near Rose, Herefordshire (Sutton's Mammoth); second, £1, William Dickinson, New Park, New Forest, Lymington, Hants. Highly commended, John Moore, Warwick; commended, Sir Frederick Smythe, Acton Burnell, near Shrewsbury.

GLOBE AND INTERMEDIATE VARIETIES OF MANGOLD WURZEL (six specimens).—First prize, £2, and extra of £2 2s., Sir Frederick Smythe Bart., Acton Burnell; second, £1, William Dickinson, New Park, New Forest, Lymington, Hants. Commended: Col. North, Wroxton Abbey, near Banbury; John Hicken, Dunchurch, near Bagby.

SWEDES OF ANY VARIETY (six specimens).—First prize, £2, and extra of £2 2s., John Moore, Warwick (Bangholm); second, £1, Duke of Portland, Cliptone Park Farm, Mansfield, Notts. Commended, Alfred Hall, Westbury Farm, Westbury, Wilts (Hall's Westbury, two specimens); James Simson, Cloona Castle, Hollymount, county Mayo (two specimens); Zachariah W. Shilgoe, Adderbury Grounds, Oxon (Purple Top).

COMMON TURNIPS, White-flesh (Six specimens).—First prize, £2, Duke of Portland, Cliptone Park Farm, Mansfield, Notts; second, £1, Joseph H. Clark, Altwood, Maidenhead (Green Globe). Highly commended: Duke of Portland. Commended: Wm. Geo. Nixey, Upton Court Farm, Slough, Bucks (Greystone).

COMMON TURNIPS, Yellow-flesh (Six specimens).—First prize, £2, James Stephen, Conglass, Inverury, Aberdeen (Green-topped Aberdeen yellow); second £1, Thos. Leslie Melville Cartwright, Melville, Ladybank, and Newbottle, Northamptonshire (Aberdeen yellow-bullock). Commended: James Simson, Cloona Castle, Hollymount, Co. Mayo; Thos. Leslie Melville Cartwright (Wilson's Nonesuch).

CABBOTS, of any Variety (Six specimens).—First prize, £2, Duke of Portland, Cliptone Park Farm, Mansfield, Notts (Altringham); second, £1, Duke of Portland (Altringham). Commended: Richard Dickinson, New Park, New Forest, Lymington, Hants (White Belgian); Duke of Portland (Altringham).

Ox Cabbage (three specimens).—First prize, £2, Saml. Robinson, Shaw House, Melbourne, Derby (Robinson's Champion); second, £1, Saml. Robinson (Robinson's Champion). Commended: John Hicken, Dunchurch, near Bagby (Robinson's Drumhead).

POTATOES.

Ashleaf Kidneys (twelve specimens).—First prize, 15s., Fredk. Lythall, Spittal Farm, Banbury; second, 10s., John Choyce, Pinwall Grange, Atherstone.

Rivers' Royal Ashleaf Kidneys (12 specimens).—First prize, 15s., Fred. Lythall, Spittal Farm; second, 10s., John Choyce, Pinwall Grange.

Gloucestershire Kidneys (twelve specimens).—First prize, 15s., John Choyce; second, 10s., John Choyce.

Daintree's First Early (twelve specimens).—First prize, 15s., John Choyce.

King of Potatoes (twelve specimens).—First prize, 15s., John K. Fowler, Prebendal Farms, Aylesbury; second, 10s., John Choyce.

Wheeler's Milky White (12 specimens).—Prize, 15s., John Choyce.

Flukes (12 specimens).—First prize, 15s., Richard Hall, Great Barford, Oxon; second, 10s., John Choyce.

Dalmahoy (12 specimens).—First prize, 15s., T. B. Wright, Quarry House, Great Barr, Staffordshire; second, 10s., John Lynn, Church Farm, Stroxtan, Grantham.

Red Regents (12 specimens).—First prize, 15s., John K. Fowler, Prebendal Farms, Aylesbury; second, 10s., F. Gottwalt, Birmingham. Highly commended: John Choyce. Commended: Duke of Portland, John Choyce, Fred. Lythall.

Paterson's Victorias (12 specimens).—First prize, 15s., W. W.

Pearce, Mesaham, Atherstone; second, 10s., Fredk. Birch, Perry Barr, near Birmingham. Highly commended: W. W. Pearce.

Sherry Blues (13 specimens).—Prize, 15s., John Choyce. Any other named variety (13 specimens).—Prize, 15s., John K. Fowler (Shackel's Conqueror). First prize, 15s., Sir Fredk. Smythe, Acton Burnell, near Shrewsbury (Lapstone Kidney); 10s., Richard Hall; 10s., Duke of Portland (Dunbar Regents). Highly commended: John K. Fowler (Fowler's Seedling); John Shackel, Blenheim House, Small Heath, near Birmingham (Lapstone Kidney). Commended: John Choyce (Berkshire Hero), John Choyce (Wedington); J. H. Brakenridge, Chew Magna, near Bristol (Aldridge Kidney).

Winners of the cups for the poultry: Dorking (coloured, except silver grey) cocks of 1869.—Mrs. Arkwright, Scarsdale, Chesterfield.

Dorking pullets (coloured, except silver grey).—Henry Crowley, Broomfield, Halifax.

Cochin China (cinnamon and buff) cocks exceeding a year old.—W. A. Taylor, Turner-street, Manchester.

Ditto cocks hatched in 1869.—William Sanday, the Cliffe, Batcliffe, Notts.

Ditto hens exceeding a year old.—W. A. Taylor.

Ditto pullet.—James Cattell, Lime Villa, Bristol Road, Birmingham.

Brahma pootra (dark), cocks over a year old.—Mrs. Hurt, Alderwoaley, Derby.

Brahma pootra (dark), pullets.—Mrs. Hurt.

Polish fowl (silver), cocks of any age.—George C. Adkins, The Lightwoods, near Birmingham.

Any variety, cock and one hen of any age.—Charles F. Montresor, Stoke House, Slough, Bucks (Indian game "Bajra," bred in England).

Game (black-breasted reds), cocks hatched 1869.—Charles Chaloner, Steetley Farm, Whitwell, Chesterfield.

Game pullets (black-breasted reds).—Edmund C. Gilbert, Penkridge.

Game (duckwings and other greys and blues), cocks exceeding a year old.—Samuel Matthew, Stowmarket, Suffolk.

Game bantams (black-breasted reds), cock and two hens.—John Croaland, jun., Thorne's Lane, Wakefield.

Ducks (white Aylesbury), drake and one duck.—Mrs. Burrell, Stoke Park, Ipswich.

Ducks (Rouen), Thomas Statter, Stand Hall, Whitefield, Manchester.

Ducks (black East Indian), drake and one duck.—Mrs. Hayne, Fordington, Dorchester.

BUTLAND AGRICULTURAL SOCIETY.

MEETING AT OAKHAM.

The show on the whole was the largest yet held by this Society, all the available space in the Riding School being occupied by animals of one kind or another. The entry of cattle, however, was considered to be rather a poor one, being inferior both in number and quality to previous years; nevertheless there were some very fair animals entered for competition, particularly a roan ox, belonging to the Marquis of Exeter; a red steer, the property of Mr. R. Wood, Clapton, and a roan cow, shown by Mr. T. Willis, Caperby, Yorkshire. The falling of in beasts was in a great measure compensated for by the extra number of sheep, horses, and pigs. The show of sheep was good, as many as 93 animals being penned, and the awarding of the prizes in the several classes occupied the judges a long time. The number of pigs was double that of any former year, and for size and weight were never surpassed at this show. The entries in the horse classes were very numerous compared with former years, animals adapted for hunting purposes and three and four-year-olds being exceedingly well represented. There were 68 horses in all, and 7 ponies, out of which number 58 were entered as fit for hunting. The dinner, in the Exchange Hall, was presided over by Lord Aveland.

JUDGES.

Stock.—R. Doig, Lillingstone Hall, Bucks.

G. Drewry, Holker House, Lancashire.

R. Fisher, Leconfield, Yorkshire.

Horses.—The Hon. Col. Lowther, Barleythorpe Hall.

The Hon. G. J. Noel, M.P., Catmose.

R. Lucas, Edithweston.

CATTLE.

Ox or steer, of any breed or weight, exceeding three year and three months old (open to all England).—First prize, £15, Marquis of Exeter, Burghley Park; second of £7, Sir W. de Capell Brooke, Geddington Grange.

Ox or steer, of any breed or weight, not exceeding three years and three months old (open to all England).—First prize, £10, R. Wood, Clapton; second of £5, T. Pulver, Broughton.

Cow, of any breed, age, or weight (open to all England).—Prize, £10, T. Willis, Caperby, Yorkshire.

Steer, under two years and six months old, fed within the district.—First prize, £10, R. Searson, Cranmore Lodge; second of £5, C. J. Bradshaw, Barley-on-the-Hill.

For the best beast shown in the Open Cattle Classes.—Prize, Coppingham school medal and extra premium of £25, R. Wood.

Tenant farmers for the best cow above three years old.—First prize, £10, W. Fowler, Manton; second of £8, R. Searson.

Tenant-farmers for the best heifer above two and under three years old, bred within the district.—First prize, £7, R. Searson; second of £5, C. Chapman, Exton.

Tenant-farmers for the best heifer under two years old, bred within the district.—First prize, £7, R. Searson; second of £4, C. Chapman.

Young bull above twelve and not exceeding twenty months old.—First prize, £10, Marquis of Exeter; second of £5, T. Swinger, Langham.

Cow in milk.—First prize, £5, J. Harris, Langham; second of £2, T. Clarke, Edithweston.

Heifer under three years old.—First prize, £4, W. Rudkin, Oakham; second of £2, G. Chester, Waltham.

Heifer calf above six and under twelve months old.—First prize, £2, Mrs. M. Hammond, Egleton; second of £1, W. Hubbard, Langham.

Breeding beast shown as extra stock.—Prize of £5 5s., R. Searson.

Best beast shown in Classes 6, 7, 8, 10, 11, 12, or 13.—Prize of £10, R. Searson.

Fat beast above two years and six months old, shown as extra stock.—Prize of £5, T. Pulver, Broughton.

SHEEP.

Three long-woolled fat wether sheep, one year old (open to all England).—First prize, a silver cup or £10, B. Painter, Burley-on-the-Hill; second of £5, Lord Berners, Keythorpe Hall.

Tenant-farmers for the best three long-woolled fat wether sheep, one year old, bred and fed within the district.—First prize, £10, B. Painter, Burley-on-the-Hill; second of £5, W. Shipman, Eaton Lodge.

Four long-woolled breeding ewes, bred within the district.—First prize, £5, Colonel Lowther, Barleythorpe Hall; second of £3, W. Shipman.

Four long-woolled ewes, bred and fed within the district.—First prize, £5, Colonel Lowther; second of £3, W. Shipman.

Four long-woolled wether lambs, bred and fed within the district (ram lambs excepted).—First prize, £4, Colonel Lowther; second of £3, W. Shipman.

Four long-woolled ewe lambs, bred and fed within the district.—First prize, £4, Colonel Lowther; second of £2, W. Shipman.

Best Sheep shown as extra stock (open to all England).—Prize of silver medal value 5 guineas, T. W. D. Harris, Wootton.

PIGS.

Best fat pig under 18 months old (open to all England).—First prize, £5, R. Pawlew, Manton; second of £3, Carver and Sons.

Fat pig, under 10 months old, not to exceed 30 stone live weight (open to all England).—First prize, £5, R. Pawley second of £3, W. Carver and Sons, Ingarsby.

Fat pig of any weight.—First prize, £3, T. Munday, Langham; second of £1, G. Smith, Ashwell.

HORSES.

Mare for agricultural purposes.—First prize, £5, J. Silverwood, of Thistleton; second of £3, T. Woods, Wychley Warren.

Cart horse under seven years old.—First prize, £5, T. Woods; second of £3, C. J. Bradshaw, Burley.

Hunting mare or gelding above five years old (open to all England).—First prize, £20, J. Drage, Moulton Lodge; second of £10, B. F. Drage, Hannington.

The best four-year-old hunting mare or gelding, bred within the district.—First prize, £20, B. Prior, Leighton; second of £10, R. L. Healey, Hambleton.

Farmers or tradesmen for the best three-year-old hunting mare or gelding, bred within the district.—First prize, £10, T. Cross, Guadalupe; second of £5, R. Stokes, Allerton.

Tenant farmers or tradesmen for the best mare for breeding hunters.—First prize, £5, J. Hornsby, Grantham.

Hackney mare or gelding under seven years old, not exceeding 15 hands.—First prize, £10, R. H. Hack, Stapleford; second of £5, E. Gimson, Southorpe.

Ponies under seven years old, not exceeding 13 hands.—First prize, £3, C. J. Bradshaw, Burley; second, a hunting whip, N. Whitechurch, Melton.

THE DORCHESTER FARMERS' CLUB.

At the dinner following the show, Mr. FORESTER, the chairman, said: Regarding the proceedings of the year some very interesting subjects had come on for discussion; the meetings had been very well attended. He was happy to say that the same fault could not be found regarding the meetings was found at Dorchester. At the last meeting 34 members were present, which was not a large number for the Blandford Farmers' Club. He hoped that as time went on the members would rally round the chairman. A most gratifying fact in connection with his presidency was the accession of 19 members to the club—intelligent young farmers of that neighbourhood, and also including two or three professional gentlemen of the town. This filled him with great hope as to the future success of the club. He sincerely trusted that as time went on the club would continue to prosper. He had really little doubt of it himself. He was sure that a considerable amount of good had been derived from the expression of feeling and interchange of ideas at their meetings. He must confess that at one time—when the Chamber of Agriculture at Dorchester was formed—he was rather afraid that the little club of Blandford would fall into the shade. Dorchester, however, was not conveniently situated, and the existence of these local Farmers' Clubs was, therefore, highly essential to the success of agriculture.

Mr. ALLEN, of Tisbury, one of the judges, said: This year there had not been a very large show; consequently the duties of the judges were not arduous. He was pleased to observe that the prizes did not take the form of plate, but were in the current coin of the realm, thus enabling the winners to do whatever they liked with the money.

Mr. HARDING also replied. In his opinion the show, as far as numbers of animals on the ground went, might be set down as a failure; still it must be admitted that some very superior animals were shown. He perfectly agreed with Mr. Keynes that it was the duty of members of the club to bring their stock out. These shows were very beneficial to young farmers, who were afforded the opportunity of marking the difference between good animals and bad ones, and therefore were materially assisted in their judgment in the selection of stock. He was indeed pleased that the show was now so well established, for he claimed the credit of having assisted to originate it.

Mr. FORD said that it had been remarked that he kept his animals too well; but on this point he was of a different opinion. He had been taught by his father to pay particular care of the young stock, not to give them inferior food. He had made it a rule to keep the young stock as well as possible. He had been pleased that day to hear the Southdowns commended. He knew it had been stated that the day had gone by for Southdown—that they would go out and make way for a better class of sheep. But he entertained a different opinion. He did not think, however, that there were any sheep which suited the Dorset hills better than the Southdowns, with their strong good constitutions. Another thing, if they wanted good mutton they must have it from the Southdowns. They knew very well that there were different opinions respecting stock, and he dare say that some of the grocer and bigger animals were suited for some of the lowlands. "The improved" Hampshires were very justly called so, because they were very much improved compared to what they were 20 years ago.

Mr. R. FOWLER had observed that a blue-book had been published, containing some "startling revelations" as to the life of the Dorsetshire labourer and his family. The evidence of a shepherd's wife near Blandford, as taken by Mr. Stanhope, the assistant-commissioner for the district, under the Women and Children's Employment Commission, was recorded in this blue-book. He (Mr. Fowler) intended to get the whole report, which should, he thought, be taken into consideration by all the clubs of the county. And he hoped the doors would not be shut to the reporters of the public press. It appeared that the Dorchester Farmers' Club had determined to try the experiment of excluding reporters from their meetings; but he for one believed that no society could possibly succeed to any great extent without the aid of the public press.

PRIZE LIST.

JUDGES.—Messrs. G. Harding, Newbury; Allen, Tisbury; and E. Sims, Pitcombe.

HORSES.

Cart mare or gelding, worked regularly on the farm.—First prize, £3, J. Coate, Hammoor; second, £1, G. Keynes, Speabury.

Cart mare or gelding.—First prize, £3, J. Coate; second, £1, G. Keynes.

Hackney gelding or filly, under four years old.—First prize, £3, J. Rooster; second, £1, R. Dornay, Pimpers.

Cob, under 14 hands 3 inches high.—First prize, £3, G. Keynes, jun.; second, £1, W. Warren, Chettle.

SHEEP.

Pen of six six-tooth Hampshire Down ewes in lamb.—Prize, £2, R. Rogers, Chettle.

Pair of Hampshire Down ram lambs.—First prize, £2, R. Rogers; second, £1, J. Friend, Gussage.

Six Hampshire Down ewe lambs.—First prize, £2, R. Rogers; second, £1, H. Ford, Gussage.

Pen of six six-tooth Southdown ewes in lamb.—First prize, £2, H. Fookes, Whitechurch; second, £1, G. Keynes.

Southdown ram.—Prize, £1, H. Fookes.

Pair of Southdown ram lambs.—Prize, £2, H. Fookes.

Pen of six Southdown ewe lambs.—First prize, £2, and second, £1, J. Ford, Raston.

CATTLE.

Dairy cow.—First prize, £3, R. Eyers; second, £1, C. C. Bartlett, Durweston.

Heifer under three years old, in calf or in milk.—First prize, £3, and second, £1, J. Ford.

Heifer under two years old.—First prize, £3, C. Flower, France Farm; second, £1, C. C. Bartlett.

Pair of working oxen.—First prize, £2, C. Flower; second, £1, J. Ford.

Pair of steers under three years old.—First prize, £3, and second, £1, J. Ford. Highly commended, J. Coate.

PIGS.

Breeding sow, in farrow or with her litter.—First prize, £3, J. Coate; second, £1, H. Senior, Hinton St. Mary.

Boar.—First prize, £3, J. Coate; second, £1, T. Fry, Iwerne Minster.

CORN AND ROOTS.

Sack of barley.—Price, £1, J. Ford. Highly commended,
C. Flower.
Sack of oats.—Price, £1, T. Fry.
Twelve mangold wurtzels.—Price, £1, S. Davis, Blandford.

Twelve swedes.—Price, £1, J. Friend, jun. Highly com-
mended, W. Arnold, Blandford.
Twelve turnips.—Price, £1, G. Groves, Milborne St.
Andrew. Highly commended, G. Hill.

THE NEW MARKETS IN LONDON.

The necessity of open markets in the centres of consump-
tion, is so obvious, that on the large scale their existence
within reasonable distance is the one circumstance that re-
gulates not only the question of profit and loss in favour of
the producer, but that also of production itself. Without a
market within a reasonable distance, affording a demand at
a remunerating return, production must be confined to the
local consumption. This is one of the laws of social
economy. Markets are equally needful between the re-
tailer who comes between the wholesale dealer and the
final consumer; and these must be placed or held in situa-
tions the most convenient for the buyers, so that they may
supply themselves at the least expense of time and labour,
both of which, to an industrious man or woman, are of
considerable importance.

The eastern districts of London are badly supplied
in this way. We know of none of any importance
beyond Whitechapel in the east, and north and north-
west of Aldergate Street; and the want of such
centres of domestic commerce is so palpable, that two
very costly efforts have been made to supply the deficiency.
The demolition of whole streets at Somers-town and the
Pancras-road, to make room for the terminus of the
Midland Railway, left a considerable unoccupied space,
which suggested to some enterprising individuals the idea
of erecting upon it a large market for general purposes.
A company was formed, and the idea carried into effect in
the most complete manner. The shops were most of
them let to respectable tradesmen, some of whom had
taken shares. But the result was a failure. The
people in the neighbourhood, most of whom are of
the working classes, would never go to the new market,
nor would the costermongers, by whom those classes are
chiefly supplied, take their stand in it. The conse-
quence was that after a short struggle the shops were
abandoned, and King's-cross Market shut up.

A similar attempt has been made in the neighbourhood
of Shoreditch, one of our largest centres of consumption.
This effort was made by the benevolent Miss Burdett Coutts,
who, having erected a large square for the benefit of the
working classes, conceived the idea that a market would be a
great accommodation to that populous neighbourhood.
No expense was spared in the erection, and every inducement
of accommodation for both buyers and sellers was
provided in the arrangements. The institution was in-
augurated with a religious service, at which the bishop of
the diocese officiated. The shops were most of them let,
and everything looked promising. But, like its prototype
at King's-cross, it does not succeed. Many of the shops
have been given up, and *Columbia Market*, instead of
being self-supporting, is nearly ignored by the dense
population for whose benefit it was erected. It is said
that, if even the numerous tenants of Columbia-square,
who enjoy the benefits of Miss Coutts' outlay in its
erection, would patronise in their turn this second effort
of hers, it would alone turn the scale in favour of its sup-
port; but they will not do so.

It is painful to see the efforts of either public bodies or
private individuals, calculated to promote the comfort of
whole neighbourhoods, rendered abortive by the neglect
and indifference of those on whose co-operation the pro-

jectors depended for their success. It is true, in this latter
case, there were some errors committed in the first instance
by the undesigned exclusion of one class of dealers from the
market. The men referred to and the costermongers, who, in
the absence of regular markets, have grown into a formidable
body, by whom the working classes are chiefly supplied with
every kind of provisions. These irregular tradesmen, as
they may be termed, were invited to take stands in the
open area of the new market, paying at the rate of 1s. 6d.
per week, or £3 18s. per annum. Now, these men had
never been accustomed to pay anything for standing-room
on the edge of the pavement, or for driving the trucks or
donkey-carts about the streets, and besides, eighteen-pence
per week was no small tax upon their slender means; and
they at once declined the contract. The charge was next
reduced to a shilling a week, with no better effect.
Finally they were admitted free of all charge; but the
mischief was done, and they have pertinaciously declined
to accept even the free standing. The reasons for this
refusal to attend the new market are not solely the charges
levied. The tradesmen of the *passé* and of the open
street are the men who, by pitching their stalls in the
positions most convenient to their customers, and by
driving their donkey-carts or hand-trucks through
the streets literally serve goods at the very doors,
and at a cheaper rate than the regular tradesman, for a
very obvious reason. They are the men who clear off the
surplusage of vegetables, fruit, meats, and even in some
cases fowls and game, from the wholesale dealers, which
otherwise would not keep good another day, and which,
on that account, especially towards the end of the week,
must be sold at some price, or entirely lost. The coster-
mongers, therefore, are a most useful body of tradesmen,
however their noisy invitations to purchase may annoy the
quiet of a respectable street; while, on the other hand, the
wives of the working men supply themselves readily, and
at a cheap rate, with the articles they want for the same
or the next day, without leaving their families to go to
the regular shops. Whether the offer in the first instance
of a gratuitous stand in the area of the new market would
have induced them to attend it, is a question it is too late
to determine; but assuredly their refusal to do so under
the circumstances, has kept away those also of whom they
depend for their support—the working people, who, cling-
ing to old associations and old habits, resolve still to
patronise the men who bring the goods they require to
their doors at a cheaper rate than they can purchase at of
the regular tradesmen. In an economic point of view the
costermongers are a most useful body. They are the
scavengers of the wholesale dealers, clearing off the surplus
of supply. We know of no way of winning these
peripatetic and noisy dealers to the support of the new
market but an Act of Parliament prohibiting their irregu-
lar way of conducting their business; and we are very
sure that no Government would make such a law.

Of the more respectable tradesmen who, in the
first instance, took shops in the new market for two years,
many have already abandoned these, being quite hopeless
of inducing the neighbouring families to purchase there,
or of establishing a trade that will afford them a profit.
It is not at all improbable that by the time the two years are

expired the whole of the shops will be relinquished. This is much to be regretted; for it is probable that, by perseverance and by a liberal mode of dealing, the surrounding population might be induced to frequent the market. If we do not mistake, Farringdon Market was under a similar cloud in the first instance. It was a so much finer place than the old ram-shackle congeries of wooden booths, tents, and stalls that previously occupied the middle of Farringdon-street from Snow-hill to Bridge-street, that people fought shy of the new square. This, however, by degrees, became frequented, and it is now one of the best markets of the metropolis. Whether Columbia Market will ever become thus attended depends

in a great measure on the conduct and character for perseverance of the tradesmen at present attached to it, and of the views of the benevolent friendness of the institution. If the former would still hold to it, we are sure that Miss Coutts would not shrink from the task of supporting this for a few years' until the public have learned its value to themselves. But if those tradesmen forsake it, there will be no alternative for her but to give it up and appropriate the site to some other purpose. In such case the neighbouring population will find out in time that, through their neglect and indifference, they have lost an invaluable opportunity of establishing an excellent market on a spot where it is much wanted.

ENGLISH TENANT RIGHT.

At the last meeting of the Shropshire Chamber of Agriculture, at Much Wenlock, there was a very large attendance of members, Mr. Jasper More in the chair. The subject for discussion, "A System of Compensation for Unexhausted Improvements," stood in the name of Mr. EVAN DAVIES, who said: Having received a communication from your committee that I should take the lead at a meeting held in a town in which a large amount of my public labours have centred, I at once complied with the request, and I take this decision of the committee as a high compliment paid through me to the Much Wenlock Farmers' Club, which has laboured so earnestly, and, I hope, not unsuccessfully, in upholding the rights and furthering the interests of the tenant farmers of England. It is, therefore, not by choice, but in compliance with the behests of the committee, that I now appear before you, and if I fail in the task assigned to me, let them, not me, bear the blame. In entering upon our subject, it may be asked why it is necessary to discuss the merits of a question, the principle of which is now admitted by all except a few interested ones. Why, the fact is that the Legislature refuses to take action upon any matter until a large amount of agitation has taken place upon it. All the great measures passed of late years, which the country has now cause to be proud of, have been the result of pressure from without, rather than any initiative quality from within. Indeed, we see that the result of agitation on this question in Ireland has been to obtain the recognition of this right, not because in its abstract principle it is more required there than here—not that in its bearing it is more necessary now than it was a quarter of a century ago, but that it would not be safe to delay it any longer; and if we are to believe one of the Ministers, this agitation with violence is to be rewarded, not only to the amount of all that the tenants require, but is to be accompanied with a measure of interference with the vested interests of the country little short, if any, of confiscation. As a passing remark, I will here say that, however long this just measure may be denied to us—however much we may realise the sentiment that "hope deferred maketh the heart sick," sure am I that no tenant farmer in England or Scotland would for one moment encourage or countenance those violent measures to obtain our desires which have so disgraced the movement in Ireland; nor in seeking a measure of compensation for unexhausted improvements for the tenant, do we desire, or ever shall desire, that the rights of others should be assailed or interfered with. I have said that the tenant farmer will have recourse to none but legitimate means to obtain this security for his outlay, but I cannot answer for others. If the present high price of beef and mutton continue; if the labouring population are deprived of the enjoyment of this food by its high price, and if they become cognizant of the fact that the price is caused by a want of greater supply, and that this greater supply cannot be forthcoming unless the tenant farmer gets security for his capital, or, in other words, until there is a free trade in the cultivation of the soil, be assured that such an agitation will take place on this question that it will not be safe for any Government to ignore. I have said there are a few interested men adverse to this movement, who pooh-pooh this question, asserting that "tenant right is nothing more than landlord's wrong." I at once acquit the principals at both ends of the

chain from entertaining any such feeling, but it is the middle-men who so industriously propagate such a libel on the intelligence and respectability of the tenant farmers of England. I am willing to admit that the accomplishment of our desires will militate against the powers of these men to do evil—militate against the opportunity of these men to hold in durance vile those whom circumstances have placed in their power. These men further say, "Why is this measure necessary now—farming has gone on from time immemorial without it? Why does the tenant farmer require this protection now?" "Why, in one word, he has progressed: the very cry for this protection is the surest sign of a spirit of improvement and advancement in the pursuits of agriculture."—[Corbett's Prize Essay.] Had we been content to farm as our forefathers did before us; had we been satisfied with the least possible amount of produce raised at the least possible expense; had we been satisfied to leave our fences, as Colonel Corbett said at our club dinner, seven yards wide; had we been content to have our farms undrained, to see our cattle unhoused, and our cottages uncared for—then, perhaps, the want of compensation for unexhausted improvements would have been unnecessary and would have been unasked for. But, gentlemen, what is it we require? Nothing more than what others have obtained. The landlord asked for it: why may not we? The landlords required, the landlords petitioned, and the landlords obtained from the Legislation an Act of Parliament to enable them to claim from their successors compensation for unexhausted improvements. If a measure of this description was found necessary for a life tenant, how much more necessary for a tenant at will? If a landlord, although sure of his holding for life, considered it impolitic to effect any improvement on his estate without the power to charge such improvement on his successor, how much more a tenant subject to six months' notice to quit, and such notice often the result of the caprice of an agent or the evil suggestions of a gamekeeper. If the landlord refused to trust to the generosity of his own son to recoup him for improvements effected on the estate, without an Act of Parliament to compel him to do so, is it unreasonable of us if we say we cannot trust those who are no kindred in blood and often unknown in person, unless we have an Act of Parliament to compel them to do that which is just and right? In arguing this question, let us take the case of a tenant taking a farm out of condition, as under the present system they always will be taken out of condition, since no man in his senses, if he can foresee the termination of his tenancy, will not take all out of the farm he can, if unprovided with the means to obtain compensation for unexhausted improvements. Well, this tenant, an enterprising young man, at once lays out his capital freely—drains, manures, renews fences, and brings the farm into a creditable state of cultivation. Having done so, as a tenant at will, he at once becomes a slave to the caprice of others; a wrong vote at an election, a frown from the agent, or a quarrel with the keeper may at once rob him of the chance of obtaining the benefit of his improvements, and make him feel that a drawn sword is suspended over his head by the merest thread. But this question must now be taken out of the category of landlord and tenant. With our fast increasing population, it becomes a national question, and

affecting the feeding of our teeming millions. The time is gone by for the owner of land in England to say, "I have a right to do what I like with my own." A declaration of that kind now would have the effect it once had on one high in the peerage, who was obliged to flee from the halls of his ancestors and seek refuge among the rocks and mountains of Wales. Perhaps when the great landowners maintained at their own cost a sufficient number of armed retainers to secure to them the peaceable possession of their property, and when in all probability they fed their quantum of the population, under those circumstances they might, and I have no doubt did, say, "I have a right to do what I like with my own;" but now that they have been relieved from the expense of those armed retainers—now when the country has taxed itself to keep a standing army, to maintain local forces, and a large body of police to secure the landowner in the peaceable possession of his property, the country has a right to expect that the land shall be made available in the highest possible degree to produce food for the people. Talk of our seeking landlords wrong! What do we seek? Nothing more or less than a measure that will induce us to lay out our money freely in the improvement of the landlords' property. Gentlemen, I have been often told, and I have no doubt other farmers likewise, to send my sons into Norfolk or Lincolnshire, to learn farming there; I am told they will not only see farming in the very highest state of perfection, but that they will meet with men of the greatest intelligence, men of wealth in their calling, and men of independence in action and thought. And how have these two counties so signalized themselves? Why, simply that no Norfolk man would take a farm of any land lord without a lease, and no Lincolnshire man without a clause in his agreement securing to him compensation for unexhausted improvements on the termination of his tenancy. The high position of these two counties is the very strongest argument that can be adduced in favour of the measure I have now so imperfectly laid before you; and I cannot resist calling your attention to a short extract from Caird on Lincolnshire Farming. He says that in the parish of Limbirk, sixty years ago, four tenants occupied 4,000 acres of land, at 2s. 6d. per acre, and became bankrupt (laughter). The rent is now 20s., and the tenants are prosperous. And in Blankney several thousand acres were let as rabbit warrens at 2s. per acre, which now let at 20s., and in both cases with the increasing wealth of the tenants. Mr. Caird thus sums up:—"It was very fortunate, when the time of this transaction arrived, that the leading landlords were liberal and enlightened men. They saw the advantage of encouraging tenants to embark their capital freely, and as leases were not the fashion of the country they gave them that security for their invested capital which is termed tenant right, or compensation for unexhausted improvements." So you see, gentlemen, the granting of that measure which we now desire was the means of raising the tenant from bankruptcy to a state of affluence, and the landlords' rent from 2s. 6d. to 20s. Can I say more than this? But before I sit down you must permit me to read the last paragraph from one of the Prize Essays of the Wenlock Farmers' Club. The essayist, Mr. Henry Corbett, speaking of the general advantages that would accrue from the adoption of tenant right, says: "The paramount duty of the Government, the basis of the national prosperity, is the well-doing of the people; and people at this very moment are suffering more or less from the two great evils of over-population and want of employment, and want of food. In direct antithesis to this, the producible land of the kingdom is cultivated as if there were actually a scarcity of labour. The natural question that arises here is, how comes it that one evil is not made to destroy the other by the application of the labour to the land? Simply because there is a hesitation as to embarking capital to bring them together; and yet in the face of this hesitation it is generally allowed that nothing will pay a better interest than money laid out in the improvement of the soil. The people want employment; the land wants more cultivation! The use of capital refused, and yet no use of capital known to pay better! Paradoxes explained and removed by one simple remedy and right—security. Give but that, and you make the island, as it should be, mainly dependent on its own resources for food, and its people for support" I will now move, "That it is necessary for the encouragement of a better system in the cultivation of the soil that a legislative enactment should be obtained, giving to the tenant compensation for his unexhausted improvements."

Colonel CORBETT, M.P., had attended more in the hope of listening and learning than of making any remarks of his own; but after the very able and eloquent manner in which Mr. Davies had brought the subject before them, it was only properly respectful to him that the matter should meet with proper consideration. He agreed entirely with Mr. Davies that no prudent man in his senses would think of investing a large capital in a farm without a reasonable probability of compensation for unexhausted improvements; but few landlords would be so far wanting in all that was honest, upright, and proper as to eject a tenant because of his vote or of the captiousness of an agent or an ill-conditioned keeper. Every man who embarked his capital should feel himself safe from any interference of that sort. There was, however, a great deal of difficulty in the way of legislative action, and the subject required consideration. Certain improvements nobody would doubt being improvements: still there must be considerable power left in the hands of landlords to say what were really improvements, and how far they should take place on the property. A landlord might be so situated, pecuniarily, as to be unable to undertake considerable improvements, or, in justice to the younger branches of his family, to pay at once a large sum of money. Under a lease a man would know exactly how many years he could depend upon to recoup his expenditure. Drainage was an improvement, no doubt; on wet land they would never get their money if they did not drain it; and the landlord, if left to himself, would lay out money every year, as he could afford to do it; whereas if a tenant laid out £500 or £600, and went to another farm, he might throw the whole cost at once upon the landlord and leave him in an exceedingly unpleasant position. The answer to this was, that the landlord had only to fall back upon the Government loan, and he was safe. But his experience on the subject was, that the Government loan would only admit of one cut and dried system of 4ft. draining on all land; that it did not answer upon all lands so well as shallower draining, say 3ft.; that it was the last foot which cost, as 3ft. could be done at 8d. a rood, while it would take at least 13d. to go the fourth foot; and that the landlord could not, therefore, fall back altogether upon the Government loan to repay him for unexhausted improvements. Straightening and taking up fences were of course very great improvements; but the tenant might throw the cost of all these unexhausted improvements on the landlord, and the landlord be unable to meet them. If they were to have compensation for unexhausted improvements, they should have a well-defined scale laid down, under which the tenant might recoup himself in a certain number of years, or the landlord have a little time to pay. Since he had been in possession, and also in his father's time, he had had a scheme embodied in the agreement by which a tenant had twelve years to recoup himself; if he went at the end of one year, he had 11-12ths of what he had laid out; if at the end of eleven years, 1-12th only; and so on to nothing. It was a very excellent system, and worked well. But the system that would give most satisfaction to all, if properly understood, and did give most satisfaction in all agricultural districts, was the lease; as landlord and tenant became thoroughly used to the idea they would agree that that was the best and most satisfactory solution of the difficulty. He could not get a man to take a lease. The highest rents in all England were where the land was held on lease. There was a feeling that at the end of a lease the land was always re-valued and there was a rise. Leases, however, were the best for all parties, if a man had capital enough to warrant him in taking one, varying in years according to what he undertook to do, and whether the farm was in good or bad order. A lease of fourteen years would generally satisfy people if a farm were in good order; if it were in bad order, twenty-one years; and if it were in such a condition that it was like reclaiming waste land, thirty years would be none too much. Whatever the decision of the Chamber, this discussion could lead to nothing but good to both landlord and tenant.

Mr. J. BRIDGES, who seconded the resolution, fully concurred in all that had fallen from Colonel Corbett. The late Duke of Richmond offered to give every one of his tenants a lease if they would go and ask for it, and they said that they were perfectly satisfied. His grace told them that, although he should not take any advantage of them, his life could not last for ever. Depend upon it "that which cannot speak cannot lie;" and when the tenants had leases in black and white, they were safe, whatever took place. Some eleven

years ago he offered a nice little farm, in the Southern division of the county, either on lease or on a well-considered plan of compensation for permanent improvements. There were 200 applicants, but none would take it on lease, and only five or six seemed to entertain the notion of a system of compensation. At last he let it on a mere verbal agreement for a lease; but the estate being left him by will, it was found that he had not power given to him to lease. Consequently he was thrown upon his back, and the tenant was very ready to take advantage of it. This he believed to be the case in many instances. How primogeniture would be dealt with he did not know; but they should have to go to Parliament for a new law as a foundation for a system of dealing with the land. A succeeding tenant might not agree with his predecessor as to what should be considered permanent improvements. The subject required to be looked into; there was a very great deal to be said on each side of the question, both as to landlord and tenant. The other day he advertised for a farm, or a friend, and found that there was one to be let in Worcestershire. He wrote that he wanted the refusal of a farm fairly free from the curse of game. The parties wrote: "We believe the farm you refer to in Worcestershire is still open, although we are not authorised to offer the refusal of that or any other farm. As the owner may be in treaty with some one else, we cannot, of course say that by applying to him you can have it. In his letter to us he omits all mention about game; so that we cannot tell you, for certain, whether the tenant will have the game or not. He states, however, upon other matters, that, 'desiring to be upon the best of terms with all my tenantry, and of being united in religious and political views—namely, all of the Church of England and heartily Conservative—I would not willingly receive into the parish any person having decidedly different views or principles.' We understand that the landlord bears the reputation of being a 'good sort' of proprietor; but we were not advised in what respect he is entitled to that somewhat vague characteristic." These words showed that something required to be done on the question of landlord and tenant. There was justice and right on each side; and it only required consideration to enable the great majority of Englishmen to come to a right decision on the subject.

Mr. STANLEY LEIGHTON recognised in the fact of this discussion a desire for more careful conditions and more business-like agreements as to the cultivation of the land, the very means of promoting good relations between those interested in the soil. It was worthy of consideration how far those particular conditions which we found in taking houses could be applied to farming operations. In taking houses a careful inventory was made, and a clause that at the end of the tenancy there might be a claim for dilapidations; but when changes of farm tenancy occurred, it would be generally found that a great many of the repairs covered by such a clause fell upon the owner of the land. It would be a hardship if the owner should also have a claim against him for unexhausted improvements. It was true that the improver did not always receive the benefit of his improvements; and also that a man very often went away from a farm without paying for the damage he had done. There were differences of tenure and practice in different parts of England—it would be difficult to apply an absolute rule. The permanent improvements fell entirely on the landlords. To call upon a landlord to pay for things which he had not authorised, and would rather not see executed, was an unwise policy. He would rather see pressure put upon a landowner to sink his capital in making improvements than give authority to an occupier to sink money to any large amount in the hope of being recouped. No doubt some landowners had virtually placed themselves in the position of rent-receivers merely—those who were non-resident, absentees. A much larger responsibility rested upon them, and a much larger dominion over the soil ought to be accorded to the tenant. A real improvement ought to be paid for; but there were improvements, the outlay on which had been borne by the tenant, which, upon a change of tenancy, neither the incoming tenant nor the landlord might wish to have had executed. A claim for an improvement should be coupled with three conditions—first, the consent of the landlord; second, the fact that the improvements were unexhausted when the tenant left, the incoming tenant being willing to pay for those improvements and increased rent; and, third, that the outlay should have been altogether incurred

by the tenant. With such conditions, it appeared perfectly reasonable that there should be a compensation for unexhausted improvements. He disagreed with Mr. Evan Davies upon one point. They ought not to go to the Government or to the Legislature for what they could do themselves. He had little sympathy with those who, having matters in their own control, should ask the Government to interfere and overrule contracts which they independently made themselves. On the contrary, in a Chamber comprising the *élite* of Shropshire agriculturists, he felt that he should not offend them, men who were an acquisition to any neighbourhood, if he said that, having the command of all the best farms in the country, they might also command their own terms, as they were in such a majority that they held the monopoly of the market (applause).

Mr. EDWARD RAINFORTH, who had originally suggested the discussion of the subject, differed from Mr. Stanley Leighton on a few points. When land was drained it required to go through a course of high farming and high manuring, and the tenant could not do this unless he had compensation or a lease. There were plenty of soils in Shropshire and other counties which took as much as the fee-simple of the land to bring into cultivation. When a tenant drained and the landlord had the advantage of the Government loan, the agreement was one-sided; the men without large capital got into arrears of rent, and the landlords knocked them about which way they liked. The large farmers ought to press this question upon the Legislature; for it was the poor tenants, with large families, who could not take care of themselves. Unless there were a better understanding between landlords and tenants, and the tenants' property better protected than it ever had been, we should never have good farming in England. If a man expended £500 a year on manure and cake, he should have some compensation for that large expenditure, requisite to bring a farm into a high state of cultivation. In many places a tenant could not get even a piece of wood given him to repair the farm buildings, yet he might have a claim against him for dilapidations. It was the duty of the owner or his agent to ride over the farm and see that the buildings were properly surveyed and repaired every year.

Mr. JOHN BATHER had expected to hear a discussion on a system of compensation for unexhausted improvements; but he could not say that he had heard anything at all yet that would come up to his notion of such a system, nor, in fact, what were unexhausted improvements. There was an assumption that unexhausted improvements belonged to the tenant; and that, so belonging, they were a subject for compensation. He should like to have heard it proved, for it was the foundation; and if the foundation were shaky, any superstructure erected on it would fall to the ground. Errors bred by being suppressed and kept in the dark, like vermin in a corn-stack. The sooner they thrashed out the question the better; and they should all aid, taking sheaf by sheaf, dislodging the vermin, and seeing whether they could save any grain. In Shropshire they ought to consider the question of how the land was let, and not infringe the liberty of either landlord or tenant. Land in the county was let, too seldom, yet sometimes, by lease, also from year to year by written agreement; the tenant and landlord were contracting parties; and anything to fetter their liberty, either by the Legislature or anything else, they would do unwisely to bring about. A man should do the best he could. There were a number of bare tenancies from year to year without any written agreement. It was a maxim that no prudent man would invest his capital in any undertaking unless he had a reasonable security that he would receive back his capital, together with interest for his money and the care and pains he had had in employing it. Consider the pitiable case of a bare tenant from year to year without any written agreement: If he farmed well, he could not farm prudently; he must act upon probabilities, upon the temper and good feelings of his landlord—perhaps also upon the temper of the gamekeeper—and upon himself, for not being fixed to the place; notwithstanding all the improvements, if he could better himself he would go, so that in laying out the capital he had to consider not only the insecurity of the tenure from his landlord, but also his insecurity from his own feelings. A large portion of the county was farmed upon this miserable system. As to compensation, he had expected to have heard that if a tenant expended so much money on manure, or lime, or drainage, he should be repaid one-third or two-thirds—in fact, that they

would create a new system of property which would be a continual struggle between landlord and tenant, out-going and in-coming, for the in-coming tenant might be called upon to pay for ploughing that he called scratching, manure that he called dust and ashes, oilcake that he considered bran, and improvements that were very far from judicious. If they made compensation for unexhausted improvements they would only put the burden on their own shoulders. There was more readiness on the part of landlords to give leases than of tenants to take them. He would much rather have a tenancy from year to year under a landlord whom he could trust; it was better than a tenancy for a term of years, at the end of which the value might be readjusted and the rent raised. The question was: Had a tenant any claim to anything more than the return of his capital and reasonable interest? and if he got a return for his capital, what compensation ought he to receive for improvements in the land? This had not been shown yet, and he hoped to hear it before he left the room.

Mr. M. G. BENSON, as a landlord, had offered leases over and over again, and they had never been accepted. The moment they established a lease they had done with their landlords, and everything became a question between the lawyers, so that pleasurable meetings between landlords and tenants were done away with. He had spent £20,000 of his own money and the Government loan in drainage, yet did not get a halfpenny more rent than before; and although they might call him foolish, with one trifling exception he had not charged interest.

Mr. WELLINGS, a former tenant of Mr. Benson's, asserted that after certain improvements, and after he had paid Mr. Benson five per cent., he was turned out and called a bad farmer, although he "licked" every other farmer with turnips.

Mr. J. BOWEN JONES believed that fair agreements were the best, rather than leases; was strongly in favour of some system of compensation for unexhausted improvements, though he did not entirely approve Mr. Evan Davies's suggestion; and read a resolution in these terms: "That in order to promote a better system of agriculture in this country it is, in the opinion of this Chamber, necessary that the tenant farmers' capital used in the cultivation of the soil should be legally secured, with power to recover for all unexhausted improvements which shall not have been objected to by the landlord."

Mr. COOPER directed attention, at considerable length, to the leases of the Settled Estates Act, and to the Agricultural Fictitious Act (14th and 15th Victoria), giving a tenant power to remove fixtures.

The CHAIRMAN said in some counties a tenant had a complete right to compensation for unexhausted improvements. It was a question here how far the tenants ought to have a right enjoyed in other counties; and the further question was, whether he should have that right by custom or by Act of Parliament. Whether by custom or by Act of Parliament, discussion would pave the way for it. In the last 100 years custom in Shropshire had altered. Mr. More exhibited leases one hundred years old, of farms and cottages under his family, showing that leases were then the custom in Corvedale. Fifty years later the Rev. J. Plymley, grandfather of Colonel Corbett, the member for South Shropshire, drew up an agricultural survey of Shropshire, in which he said that leases were exploded by gentlemen of property, who, having previously granted them for very long terms, had been induced by injury sustained to abandon them. Mr. Plymley states that the tenant was, by the custom of the county, indemnified for the improvements in quitting his farm. This custom had changed fifty years later, as was shown by the evidence of Mr. W. P. Pinches, of Ticklerton, who, when president of the Wenlock Farmers' Club, gave important and highly interesting evidence on the state of agricultural customs in Shropshire, before a committee of the House of Commons, in 1845. Mr. Pinches then stated that no compensation was given in Shropshire to the outgoing tenant. He strongly advocated a system of tenant-right. This evidence was to the effect that agriculture had progressed in the county under the large proprietors, in whom tenants felt the fullest confidence, except sometimes in the matter of game; that two-fifths of the county was in a backward and unprogressive state, owing to the tenants having no leases, and not sufficient confidence in their landlords to justify them in expending capital. The result of the committee was,

that the views of the chairman "to render the principle of tenant-right for improvement general throughout England by giving it prospectively the validity of custom" were negatived, and resolutions of Mr. Bouverie were instead adopted. The first of these stated that the tenant-right denied did exist in several counties; that it extended to the crops the tenant sowed and left in the ground; to remuneration for the preparation of the soil for crops by tillage; for the straw, hay, and dung left on the farm, and for growing underwood; that this wider system of compensation was beneficial to agriculture, the landlord and the farmer; that it was desirable that no difficulties should stand in the way of the extension of such tenant-right; but that the committee did not recommend its being made compulsory. The question, the chairman said, before them now was whether they should try to spread the custom, or with Mr. Davies seek legislation to make what was recommended compulsory. The labours of this committee had borne fruit in two Bills, one alluded to by Mr. Cooper, by which a person with a limited interest in property could bind his successor with respect to agricultural improvements. Mr. Davies spoke strongly against views which were held with respect to tenant-right in Ireland, he yet advocated very liberal views of tenant-right in England. Mr. Bright's view of the Government advancing money to enable farmers to purchase land from landlords willing to sell, which Mr. Davies stigmatised as confiscation, was endorsed by Mr. Caird, the greatest agricultural authority, as peculiarly adapted for the state of Ireland; so that whether the idea deserved the ridicule it had received or not Mr. Davies and Mr. Caird were at issue as to its policy. With respect to absentee proprietors, if a man was a bad landlord, it is better that he should be an absentee; and if he was a good one, and only non-resident because he had property in too many counties to be able to reside in all, an occupancy under such a landlord was highly advantageous, as he could afford to spend more money on improvements than a poorer resident; and besides non-residence of a landlord may bring palpable advantages to tenants, as in the matter of game and shooting, the right which the Duke of Cleveland gave to his tenants. As to Mr. Bath's supposing that tenants put a halter round their necks if they paid an outgoing tenant for unexhausted improvements; this would answer far better than to take a farm which required three years to bring it into a good state of cultivation; and with respect to his saying that the tenants would be taken in by each other with regard to the work done, and bones and manure left, he thought the farmers entirely misrepresented by such a view being taken of their dealings with each other. Assuming them to be unanimous in favour of the claims of the tenant for compensation for unexhausted improvements, the question was, could this be obtained by the extension of the custom referred to as the Committee of the House of Commons proposed, or by legislation as Mr. Davies proposed.

The following resolution was agreed to:—"That in the opinion of this meeting it is necessary for the encouragement of a better system in the cultivation of the land that some legislative enactment should be obtained, giving to the tenant compensation for unexhausted improvements, in the case of buildings and drainage, the landlord's permission having been obtained."

BEFORE IN THE TOAST LIST.—At the dinner after the Broadwindsor Ploughing Match, last month, the first toast was "The Queen and the Royal family," the next "The Army and Navy," the third "The Bishop and Clergy," and the fourth "The Press." In giving this Captain Edwards, the Chairman, "anticipated that they would be rather surprised at the next toast. He hoped, however, that that surprise would be equalled by the satisfaction with which they would receive it. He had the pleasure of presiding over a meeting two or three days since, and then, as he had done for many years, lamented that the toast should be left almost to the end of the meeting. Ever since he had been enabled to make use of the little sense God had given him he had felt the influence of that great power which was worthy of their admiration and respect, and which, in his opinion, ought to take rank with the permanent institutions of the country—he referred to the Press. If there was one body of men more than any other indebted to the Press it was the agricultural body.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

MONTHLY COUNCIL, Wednesday, December 8.—Present: the Duke of Devonshire, K.G., in the chair; the Earl of Powis, Viscount Bridport, Lord Chesham, Lord Kesteven, Lord Tredegar, Lord Vernon, Lord Walsingham, Sir Massey Lopes, Bart., M.P., Mr. Acland, M.P., Mr. Baldwin, Mr. Barnett, Mr. Barthropp, Mr. Booth, Mr. Bowly, Mr. Cantrell, Colonel Challoner, Mr. Druce, Mr. Brandreth Gibbs, Mr. Hassall, Mr. Holland, Mr. Hornsby, Mr. Hoskyns, M.P., Colonel Kingscote, M.P., Mr. Leeds, Mr. Milward, Mr. Pain, Mr. Randell, Mr. Ransome, Mr. Ridgen, Mr. Sanday, Mr. Thompson, Mr. Torr, Mr. Turner, Mr. Webb, Mr. Wells, M.P., Mr. Jacob Wilson, Professor Simonds, and Dr. Voelcker.

The Earl of Sefton, Croxteth, Liverpool; Arthur Allison, Filgate Forest Lodge, Crawley; and Charles F. Allison, Crawley, were elected Governors of the Society.

The following Members were elected:

Dutton, John, Curbridge, Farringdon, Berks
Fenton, Kirkby, Caldecote Hall, Nuneaton
Frankish, William, Limber Magna, Uleobey
Franklin, Joseph, Little Milton, Tetworth, Oxon
Mackinder, Harwood, Langton Grange, Spilaby
Wilson, John, Kettleby Thorpe, near Brigg
Spurr, Anthony, Dowlands, Lyme Regis, Dorset
Tinley, Edward, Southwell, Nottingham
Westhorp, Rev. Richard A., Berners Roding, Ongar, Essex
Whitworth, Henry, 96, King-street, Manchester.

FINANCES.—Major-General Viscount Bridport (chairman) presented the report, from which it appeared that the Secretary's receipts during the past month had been duly examined by the committee, and by Messrs. Quilter, Ball, and Co., the Society's accountants, and found correct. The balance in the hands of the bankers on Nov. 30 was £3,067 18s. 6d. The committee recommended that Mr. J. Gale's salary be increased £20 per annum, in consideration of his long and efficient services to the Society; that a list of members in arrear with their subscriptions be sent to each member of the Council, with a request that individually he will assist in obtaining payment of such arrears; and that a sum of £3,000 be placed on deposit with the Society's bankers.—This report was adopted.

JOURNAL.—Mr. Thompson (chairman) reported the decision of the judges of the essays competing for the prize of £25, offered for an essay on any agricultural subject, awarding it to one on the Potato in Jersey, bearing the motto, "Practical." The motto-paper having been opened by the President, the essay was declared to have been written by Mr. C. P. Le Cornu, of Trinity Manor, Jersey. With reference to the prize of a piece of plate, of the value of 100 gs., offered by Mr. Mason to the occupier of the best managed farm within a certain area round Oxford, the committee made the following recommendations:—(1). That an entrance-fee of £2 be required from candidates who are members of the Royal Agricultural Society, and of £3 from all other competitors; (2). That the competition be confined to tenant-farmers; (3). That no farm be allowed to compete which does not contain at least 200 acres; (4). That a second prize of £50 be awarded to the 2nd best farm; (5). That no entry be received later than Saturday, February 26; and (6) that the certificate of entry shall contain the name and address of the candidate and of the proprietor of the farm, the kind of soil (light or heavy), the acreage of the farm, and

its distance and bearing from the nearest town.—This report was adopted.

CHEMICAL.—Mr. Wells (chairman) presented the report of the committee, which contained the annual report of the consulting chemist. This report was referred back to the committee for the purpose of enabling them to select certain portions of it for publication in the agricultural newspapers.

VETERINARY.—Lord Bridport (Chairman) having presented the usual annual report, Mr. Jacob Wilson drew the attention of the Council to the question of the equivalent which the Society obtained for the annual grant of £200 to the Royal Veterinary College. After a conversation, it was resolved (with two dissentients) that the Veterinary Committee, after conferring with the governing body of the Royal Veterinary College, be requested to make a special report to the Council, on the suggestion made by Mr. Jacob Wilson, that a portion of the grant of £200 be in future placed at the disposal of the Veterinary Committee, to obtain reports on special subjects of interest connected with veterinary science—the committee to report to the Council at their meeting in March.

SHOWYARD CONTRACTS.—Mr. Randell (Chairman) reported that the plan of the showyard for 1870 had been placed in the hands of the Local Committee at Oxford, to enable them to proceed with the levelling required, which is now in progress; and that the arrangements for the railway siding, and for the supply of water to the ground, had been satisfactorily determined. This report was adopted.

SELECTION.—Mr. Thompson (Chairman) reported that the Committee had completed the revision of the bye-laws, but desired to take the instructions of the Council as to certain points. They also recommended that a copy of the new edition of the charter, bye-laws, and resolutions of Council be sent to each member of the Council, and to all future members of the Society on their election; and that the same be printed in the next number of the *Journal*, and circulated amongst the present members of the Society. It was also recommended that the annual report of each standing committee shall contain a list of its members, omitting those who have absented themselves during the whole year, and that it shall contain the names of those proposed to be added to the list for the ensuing year. The questions relating to the bye-laws having been disposed of, and the other recommendations of the Committee adopted, the Chairman stated that the Committee had agreed to recommend Mr. Charles Whitehead, of Barming House, Maidstone, to fill the vacancy in the Council caused by the election of his Grace the Duke of Devonshire, K.G., as a Vice-President. Mr. Wells, M.P., having proposed, and Mr. Randell seconded the nomination of Mr. Whitehead, an amendment, substituting the name of Mr. R. Russell, of Farningham, was moved by Mr. Cantrell, and seconded by Mr. Ridgen. On a show of hands, the amendment was lost by one vote, the numbers being for Mr. Russell 11, and for Mr. Whitehead 12.

The Secretary was instructed to communicate with the local authorities at Chester, Shrewsbury, Stafford, and Wolverhampton, informing them that the Society's country meeting in the year 1871 will be held in the district including Cheshire, Shropshire, Staffordshire, and North Wales.

Mr. Sanday, having given notice that he would move

"that the rule for the non-payment of judges who are members of the Council be rescinded," stated that as no such rule could be found, his resolution was unnecessary. It was therefore moved by Mr. Milward, and seconded by Mr. Thompson, "that Mr. Sanday and Mr. Bowly be paid for their services at Manchester;" whereupon, under clause 36 of the bye-laws, Lord Bridport requested that the consideration of the question be deferred until the next monthly Council. On a show of hands the question being deferred, Lord Vernon gave notice that at the next monthly Council he should move "That judges who are members of Council may be paid for services rendered to the Society."

The Earl of Lichfield gave notice that at the next monthly Council he will call the attention of the Council to the inconvenience arising out of the conditions of the charter fixing the date and place of holding the general meeting, and excluding from the Society's meetings the discussion of all subjects having reference to measures pending, or to be brought forward in either House of Parliament.

The standing committees for the year 1870 were appointed.

The report of the Council to the half-yearly general meeting was prepared.

A letter from Mr. W. A. Gibbs on the harvesting of hay and corn in wet seasons was referred to the Implement Committee.

The Council having given the usual leave of absence to the secretary and clerks, adjourned over the Christmas vacation.

At a special Council, which met, by order of the President, at the rising of the monthly Council, the stock and implement prize-sheets for the Oxford meeting were arranged, certain prizes for Dorset sheep having been added to the draft of the former, on the motion of Lord Bridport.

The annual meeting of this Society was held at noon, on the Thursday, in Hanover-square; the President, His Grace the Duke of Devonshire, in the chair. The attendance was somewhat above the average.

The SECRETARY (Mr. H. M. Jenkins) read the following

REPORT OF THE COUNCIL.

Since the last General Meeting in May, 2 Governors and 32 Members have died, and 4 Governors and 182 Members have been elected, so that the Society now consists of

75 Life Governors,
75 Annual Governors,
1,469 Life Members,
3,962 Annual Members,
16 Honorary Members,

making a total of 5,597, and showing an increase of 86 for the year 1869.

The half-yearly statement of accounts to the 30th of June, 1869, has been examined and approved by the auditors and accountants of the Society, and has been furnished to all members in the last number of the *Journal*. Owing to the great financial success of the Manchester meeting, the funded capital of the Society has been raised to the sum of £20,000 Stock in the New Three per Cents., while an additional sum of £4,612 7s. 8d. New Three per Cents. has been invested as a Reserve Show Fund. The Council regret that owing to the continued difficulty experienced in collecting arrears of subscription, they have been compelled to take legal proceedings against some members of the Society; but they have obtained the only satisfaction possible under such circumstances; the arrears have been paid, and the legality of the Society's claims has been most clearly established.

Under the Presidency of H.R.H. the Prince of Wales, the Manchester meeting attained an unusual degree of success. Their Royal Highnesses the Prince and Princess of Wales honoured the Exhibition with their presence on two occasions. The expectations of the Council as to the magnitude of the meeting

were even surpassed by the result. The entries of implement largely exceeded those at any previous meeting of the Society, and the exhibition of stock was on a still more extended scale. The crowd of members and visitors more than doubled in number those who were admitted to the Show-yard at Leicester, and the amount received for admission was proportionately large. The interest created by the magnificent exhibition of live stock and implements may be estimated by the fact that more than a thousand pounds was realized by the sale of catalogues.

The Local Committee carried out the various arrangements which had been entrusted to them with remarkable zeal and liberality; and their secretary (Mr. Whitworth) in particular was untiring in his exertions to promote the success of the meeting. Considering that during the six days of the show it was visited by more than two hundred thousand people, the Council believe that no slight praise is due to the arrangements by which so large a number of persons could obtain excellent refreshments without inconvenience, and at a moderate price—the more so as these arrangements were made by Mr. Whitworth with the advantage of a considerable profit to the Society. Mr. Whitworth's indefatigable efforts on behalf of the Society induced the Council to request his acceptance of the sum of one hundred and fifty guineas as an acknowledgment of his services.

The great agricultural feature of the meeting was, no doubt, the careful and prolonged trials of reaping and mowing machines; and, whether tested by the interest exhibited in them each day by crowds of intelligent spectators, or by the great increase in the extent to which reapers were reported to have been used during the following harvest, there can remain no question that the Society's trials of implements at Manchester have already yielded good results.

On the two Sundays during which the stock was in the yard, Divine Service was performed by the Vicar of Stretford, before large and attentive congregations, chiefly composed of the servants in attendance on the animals.

The Council have fixed the commencement of the Oxford meeting for Monday, the 18th of July. They have decided that the live stock shall all be in the yard by four o'clock in the afternoon of Saturday, the 18th day of July, which will allow of the animals recovering from the fatigue of the journey to the show (and thus place those which have travelled from distant counties more on an equality with others which have come only a short distance), before the judges commence their inspection on the Monday morning following. The show will close on Friday, the 22nd of July, at four o'clock, thus enabling most of the stock to commence their homeward journey the same evening, and to arrive at their destination before the following Sunday morning.

In addition to the usual classes contained in the stock prize-sheet, the Council have offered for competition at Oxford prizes for Norfolk and Suffolk polled cattle, for Dorset sheep, and for Lincoln as distinguished from other long-woolled sheep. The Oxfordshire Agricultural Society has offered special prizes for pairs of dairy cows, for Oxfordshire Down sheep, and for hackneys; and the Local Committee have offered prizes for a class of four-year-old, and for another of older hunters.

The High-Sheriff for Oxfordshire (James Mason, Esq.) has offered a piece of plate of the value of 100 guineas, as a prize for the best-managed farm in the district included within a line drawn through the towns of Reading, Great Marlow, Aylesbury, Buckingham, Banbury, Stow-on-the-Wold, Lechlade, Wantage, and back to Reading. The Council have agreed to fix the conditions of competition; to appoint, and to defray the expenses of the Judges and a reporter; and to arrange all other details. They have determined that an entrance-fee of £2 be required from competitors who are members of the Society, and £3 from all others; that the competition be confined to tenant-farmers; that no farm shall be entered which does not contain 200 acres; that a second prize of £50 be given to the occupier of the second-best farm; that no entry be received later than Saturday, the 26th February; and that every certificate of entry shall contain the name and address of the candidate, and of the proprietor of the farm, the kind of soil (light or heavy), the acreage of the farm, and its distance and bearing from the nearest town.

The schedule of prizes for implements and machinery to be awarded at Oxford contains classes for fixed steam-engines, horse-gears, mills, crushers, chaff-cutters, oilcake-breakers,

tarnip-cutters, steaming-apparatus, dairy implements, bone mills, guano breakers, coprolite mills, flax-breaking machines, tile machinery, and draining tools.

The continually increasing number of implements exhibited at the country meetings of the Society has compelled the Council to consider by what method a sufficient number of Judges in each department could be appointed beforehand, and also by what means a large portion of the time of the Judges, hitherto devoted to a preliminary examination, and a selection of implements for trial, could be advantageously economized. The Council have therefore resolved that every implement intended by the exhibitor for competition shall be entered in its respective section and class *for trial*, at the time when the specification is sent in to the Secretary; but, notwithstanding such entry, the discretion of trial will rest with the Judges; also, that no exhibitor may enter more than one implement of the same construction for competition in any one class. Further, in order to protect the interests of purchasers, it has been resolved that, although certain implements belonging to the classes for which prizes are offered are not entered for trial, the Stewards may, on the recommendation of the Judges, order any of them to be tried, and their capabilities made public.

The attention of the Council having been drawn to the increasing adulteration of manures and feeding cakes, especially guano, nitrate of soda, ground bones, and linseed cakes, Dr. Voelcker has been requested to submit to the Monthly Council in March, June, and December, a report of the various samples forwarded to him by Members of the Society, so that such report, together with the names of the dealers who supplied the substances analysed, shall, if the Council think fit, be published in the *Agricultural Journals*.

The Society's Educational examinations in April last were conducted on the same plan as those of the previous year, and the results were so satisfactory that the Council have renewed the grant (£200) for the year 1870, with this alteration, however, viz., that whereas, hitherto, it has been considered advisable not to fix any limit to the ages of candidates, in order that *all* comers might be admitted during the earlier stages of our proceedings, it has now been thought advisable to fix a maximum of age for candidates; no one who has passed his 21st birthday before March 31st, can in 1870 be admitted as a candidate for the Society's honours and prizes.

By order of the Council,

H. M. JENKINS, Secretary.

Lord DENMAN, in moving the adoption of the Report, said he considered it highly satisfactory. The Exhibition at Manchester was, as they all knew, a very successful one, and every effort should be made to render the Meeting at Oxford in July next equally successful. In his own neighbourhood a disease had prevailed among cattle which seemed to be quite incurable—he meant black-foot, or speed; and he thought that if a prize were offered for the best essay on that subject, it would produce good results. Great exertions would be required to make the Meeting next year anything like equal to that which was held in a populous and enterprising town like Manchester, and presided over by the illustrious Prince who was heir to the throne.

Mr. CALDWELL in seconding the resolution said: As regarded the prize of 100 guineas offered for the best managed farm in the Oxfordshire district, he said he thought it would not be enough to state the acreage of the farm, distinguishing between light and heavy, but it should also be stated what number of acres was in grass and what number in arable (Hear, hear). They all knew that a good dairy farmer might not be a good arable farmer, or a good arable farmer a good dairy farmer (Hear, hear). With respect to the miscellaneous articles exhibited, it would, in his opinion, be an advantage to the society, besides tending to lighten the labours of the judges, of whom he had for some time been one, if those who exhibited were required to send in a good description of their articles, and if some attempt were made by the Council to define what miscellaneous articles could be considered useful to agriculturists.

Mr. C. S. READ, M.P., said he wished very much that the report just presented had contained some reference to the Society's *Journal*. He would take that opportunity to express his sense of the marked improvement exhibited in the last number of the *Journal*, which he considered more practical and useful than any number that had been issued for a great

many years (cheers). He hoped that the inspection of the farms of leading agriculturists would be continued, and that they would have many reviews of such farms in future numbers of the *Journal*. He could not help remarking how singularly opportune was the account of the Castle-acre Farm, which appeared in the last number of the *Journal*, when Mr. Hudson, who was so long a member of that society, had just passed away before it was printed. He considered that review most important, because it showed what could be done by the application of capital to bad or inferior land. If it were a permanent duty on the part of the British farmer to supply meat and corn and wool for the nation, no man had carried out that duty so successfully as Mr. Hudson (Hear, hear). Whether such expenditure upon high farming paid was a question which had yet to be determined, and he must say that he considered "unprofitable" and "impossible" synonymous terms in the agricultural dictionary (Hear, hear). If he might offer one criticism upon what comprised so much that was valuable, he might observe that when a gentleman was preparing, in the dull season of spring, to write a review, and to mention the wages of agricultural labourers, he should inquire what were the average wages of the labourers, instead of what were the wages paid at that particular period of the year (Hear, hear). The wages paid at Castle-acre were, he believed, put down at 11s. a week. The fact that Mr. Hudson expended £2,000 a year in wages for 800 acres of land showed that he was a good employer of labour. For two or three months in the year his men earned at task-work as much as half-a-crown a day; while at harvest time the wages amounted in some cases to £2 a week, and were never less than 30s. One word as to the future *Journal*. He expected and hoped that it would be issued as early as possible. He looked forward with a great deal of pleasurable anticipation to the report on Belgian farming, not merely, he might observe, on account of its agricultural, but also on account of its political bearing (cheers).

Mr. NEILD said, as one who was not the most inactive member of the Local Committee for the Manchester Meeting, he wished to acknowledge, on its behalf, the very handsome manner in which its exertions, and especially those of its secretary, Mr. Whitworth, were alluded to in the report. Before that meeting was held he ventured to predict that it would prove a memorable one in the Society's history, and he thought that prediction had been completely verified (cheers). He wished to remark that he thought a very large saving might be effected in the fittings of the show-yard (Hear, hear). The present arrangements precluded, he believed, the immediate accomplishment of that object; but, as the matter stood, it was not one which redounded to the credit of the managing body. As regarded the number of members, although it now approached 6,000, it very inadequately represented what should be the number of members of the Royal Agricultural Society of England. Considering the national character of that Society he thought every farmer occupying 100 acres of land should feel it his duty and his interest to belong to it. For two or three years he had advocated, both in public and in private, a drawing together of that society and the leading country societies of Great Britain. The Council had indeed taken a step in the right direction by dividing England into five districts; but that did not reach what they in the country thought was wanted. He believed that if a deputed member of the leading agricultural societies of England were a member of the Council for a year, that arrangement would work beneficially for the agricultural body at large (Hear, hear). He thought that in the present day they should look with rather conservative eyes at the progressive character of the times in which they lived. He would be one of the last to oppose or check the action of a number of territorial noblemen and gentlemen who had been so useful on the Council of that society; but he believed they had nothing to fear from having a larger infusion among them of practical tenant farmers; on the contrary, he was convinced that the more the noblemen and gentry of England were brought side-by-side with practical, sensible tenant farmers the better would it be for that great society and for all connected with agriculture. He entirely concurred in what Mr. Read had said in praise of the *Journal*. It was now a pleasure to read it, and in Lancashire and Cheshire they looked upon it as a charming book (cheers and laughter). He recollected that last year some

rather crooked work was thought to have been going on about Mr. Jenkins's appointment; but the discussion which took place did him good, it put the spur into him and he came out a winner. When the little man came down to Manchester he did well for the Society, and he believed the Society never had a better secretary (cheers). In conclusion Mr. Neild condemned the stewards and judges being required to pay their own expenses as a niggardly arrangement, unworthy of such a society.

Mr. BOTLEY said, having expressed a hope at Leicester that the *Journal* would be more popularized, he was glad to be able to concur in the remarks just made on that subject by Mr. Read. The encouragement given by the Society to education had his entire approval, and he thought its funds could not be better applied. He deprecated the increase of the investment in the funds.

Mr. T. WILLSON thought that as regards the prize for the best farm in the Oxfordshire district it would have been best to have allowed everyone to compete, instead of charging an entrance fee of £2 for members and £3 for all others. The High Sheriff of Oxfordshire could not have intended that the sphere of competition should be thus limited. He wished to know whether the Council intended to allow an exhibition at Oxford outside the showyard as was the case at Manchester. Several gentlemen had declared their determination to withdraw from the Society if that were repeated. Two or three of them wanted to see the horses shown at Leicester. Having paid their shilling they found that they could not see them unless they submitted to be mulcted to the extent of 4s. more, and after all they did not see them at all, because they did not happen to have any change in their pocket (laughter). They considered it a disgrace to the Society that such a thing as that should be allowed in order to compensate or please the local committee. If a horse exhibition was to be held outside the show-yard, why should there not be a menagerie, a penny gaff, or an Aunt Sally? (laughter). It seemed to him quite beneath the dignity of such a society as that. In conclusion he would inquire why that meeting was held on Thursday instead of on Wednesday? (Hear, hear).

Dr. CRISP thought it was a great evil for a society like that to go on in the old humdrum style, and assume that all that was done was right. As regarded the *Journal*, he had to complain of the absence of any report or summary of foreign agricultural matters; and he held that it would be a great improvement if the Editor would let them know what was going on in other countries. With respect to veterinary science, no good could be done so long as that society continued to pay £200 a year to the Veterinary College. The whole system was rotten to the core, and he thought the Society should advise the Government to establish one on a sound and extensive basis.

Mr. THOMPSON said he would commence the few remarks which he had to make by expressing his own great satisfaction, as a member of the Council, at the general tone that pervaded the meeting, and the practical and useful character of the suggestions made for the consideration of the Council. Twelve months ago he felt it his duty, as Chairman of the *Journal* Committee, to defend the appointment of Mr. Jenkins against what might be considered a very heavy attack (laughter). He had to bear the brunt of that attack, and it was very gratifying to him to find, after the lapse of twelve months, that Mr. Jenkins had not only justified his appointment and taken the place of an average editor, but by almost unanimous consent was adjudged to show that progress which they all wished to see in the Society. Lord Deunam had referred to a disease among cattle from which he (Mr. Thompson), among others, had suffered considerably. He would mention a cure which he had found very effectual, and that was setoning, beginning to seton very early, when the calf was about six months old, and keeping it up for the first three years. Before he had recourse to that he suffered great losses among his calves. Those in his neighbourhood who had adopted setoning had, like himself, never had a case of the disease, while those who had not done so had had such a number of cases that they had been induced to turn their attention to it.

Mr. NEILD: You mean setoning combined with good living. Mr. THOMPSON continued: Of course calves in good condition were less liable to disease than calves which were out-of-condition; but setoning did not keep down the condition of calves to the extent that might be supposed. He did not agree with Mr. Caldwell, that the miscellaneous articles exhibited at

the Show should be restricted to articles which were directly connected with agriculture. There were a great many miscellaneous articles which were interesting to a large number of visitors, and there was a large space to be filled; he saw no reason why a portion of it should not be occupied by articles which clearly tended to increase the receipts. He knew that entailed very onerous duties on the judges, but it was necessary for the good of the Society. Mr. Botley having alluded to the £20,000 invested in the Funds, he must say he considered it a great advantage to the Society to have such an investment, in order that the Society having got into a certain groove might be able to continue it and keep up its prizes. In consequence of there being no Show during the cattle plague and of the deficiency in the receipts at Bury, the reserve fund was reduced by some thousands of pounds, and it was a great advantage that in spite of drawbacks like these the Society was enabled to conduct its operations on a uniform scale. The object of the Council had been not to make large investments, but to accumulate such an amount as would suffice to meet standing expenses, so that the whole amount received at the shows might be available for prizes. As to Mr. Willson's question why that meeting was held on Thursday, he wished to say that if the convenience of members would be best consulted by holding it in future on Wednesday the Council would hold it on that day. The attendance on that occasion was rather in favour of Thursday; but it was chiefly in consequence of the meetings of the Farmers' Club, the Smithfield Club, and the Chamber of Agriculture being held previously that the meeting had been fixed for that day.

Dr. CRISP said the practice of setoning recommended by Mr. Thompson appeared to him so cruel and unnecessary as to be a fit subject for the consideration of the Society for the Prevention of Cruelty to Animals (laughter).

Mr. COLEMAN would suggest that in order to facilitate field trials the Council should send a competent person beforehand, to make, perhaps in conjunction with one of the stewards, the necessary arrangements; considerable delay having occurred before for want of such preparation.

Mr. TORR said Mr. Willson seemed to him to have fallen into an error with regard to the horses shown at Manchester. The jumping of the horses was, in fact, the result of a private arrangement on the part of the Manchester people, who took the shilling for it, and he believed realised a profit of three or four thousand pounds. If Mr. Willson's friends had waited half an hour they would no doubt have seen the animals back in their stalls in the show-yard. The feeling of the Council was decidedly against the jumping, but their Manchester friends made it a *sine qua non*, and it was assented to on the condition that the animals should return to the yard. Like previous speakers he congratulated the meeting on their having such a Secretary.

Mr. T. DUCKHAM thought that the members of the Society had a right to see everything that was entered in the catalogue during the hours that the exhibition was open; instead of which they were caught as it were in a trap so far as the horses were concerned, and found that to see them they must pay 5s. That appeared to him to be a lowering of the standard of the Society, and he hoped that the Council would not be dictated to again by a local committee.

Lord VERNON said a member of the Manchester Local Committee having observed that great economy might be effected in the fittings of the show-yard, he wished to remark as a member of the contract committee that if anything were pointed out as worthy of consideration it would receive attention (Hear, hear).

Mr. JACOB WILSON said: Mr. Duckham seemed to him to be labouring under a great mistake. That gentleman doubtless went to Manchester, as others did, to see the Show. He bought a catalogue at the door, paid his entrance-fee or presented his ticket, and saw everything in the yard that was entered in the catalogue. The jumping was quite distinct from the rest, and the horses entered for it were previously exhibited in the show-yard. It was not compulsory on Mr. Duckham, or anyone else, to pay an additional four shillings.

Mr. JONATHAN GREY said: As an old member of the Royal Agricultural Society, he would ask whether the horses that jumped compete for the prizes of that Society. If they did, it was, he maintained, beneath the dignity of the Society to allow them to go out of the yard for that purpose (Hear).

Mr. NEILD must say that some gentlemen seemed to him to be treating Manchester rather unfairly. The local committee drew a hard and fast line, and a pledge was given that every horse that went out to jump should be brought back. It was left to the pleasure of the owner whether an animal should go out of the yard or not.

Mr. DUCKHAM: That should not have been the case.

Mr. NEILD said that was a matter of opinion. The result, as regarded the local committee, was that it was sadly out of pocket. The banquet cost them £1,200, and notwithstanding the character given to Manchester for grasping and greed ("No, no"), he believed the Society never went into a district where the members were treated more handsomely (cheers). He was really sorry to hear such narrow views as had been expressed by some gentlemen.

Mr. CALDWELL would like to know under what rule the horses were allowed to jump.

Mr. THOMPSON referred to a paragraph on the back of the Manchester sheep catalogue, stating that there would be an exhibition of horses for leaping, prizes being offered by the local committee, in an adjoining Showyard. It was, he added, clear that the arrangements were made with the cognizance and consent of those who had the management of the Show. He hoped that discussion would not be continued any longer. Where there was much cause for mutual congratulation they should not allow a little difference of opinion to divide them (Hear, hear).

Sir WALTER STIRLING also deprecated any misunderstanding. The meeting at Manchester was, he remarked, a happy union of agriculture and commerce, which must have delighted the well-wishers of both, and which was managed on the part of Manchester in a spirit worthy of the Metropolis of the North (cheers).

The report was then adopted.

Mr. T. ASKELL, in moving a vote of thanks to the auditors, reverting to the subject of the prize for the best-managed farm in the Oxfordshire district, said he thought the competitors should be required to make a declaration that they had not cultivated their farms at a loss (laughter).

Mr. BADHAM seconded the motion, which was then put and carried.

On the motion of Mr. TORR, seconded by Mr. Neild the auditors were re-elected.

The business having thus been concluded,

The CHAIRMAN inquired, in accordance with custom on such occasions, whether any member present had any question to ask or any suggestion to offer for the consideration of the Council.

Mr. T. WILLSON having expressed a wish to know when the existing contract for the fittings of the show-yard would terminate,

Mr. TORR replied: In about two years, adding that it had led to a saving of about £1,000 a-year, as compared with the preceding contract.

Mr. DUCKHAM moved a vote of thanks to the noble duke in the chair.

Mr. C. S. READ, M.P., in seconding the motion, adverted to the appointment of secretary. He was, he said, one of those who last year ventured to criticise that appointment; but at the same time he said that he thought the Council had selected the very best man that they possibly could select. All he did was to criticise the mode of that appointment, which, he believed, was somewhat irregular.

Mr. THOMPSON would be glad if Mr. Read would point out in what respect it was irregular?

Mr. READ said: The committee having made their report, the Council were asked to select in about one minute. He thought that was treating the members of the Council as mere puppets.

Mr. THOMPSON begged entirely to deny that. The question was submitted to the Council in a regular manner, after full notice, and every member had an opportunity of opposing what was proposed.

The motion of thanks to the Chairman having been carried by acclamation,

HIS GRACE in acknowledging it said: It had afforded him great pleasure to listen to such an interesting discussion, and to meet with such a favourable reception from the members present.

The meeting then separated.

THE SMITHFIELD CLUB SHOW.

THE OPENING MORNING.

The most popular prize ever offered by the Royal Agricultural Society of England has no doubt been the £100 for the best horse; and the £100 for the best beast will as certainly be the most attractive feature of the Smithfield Club. For many years past the London Cattle Show has been considerably over-weighted by the Birmingham meeting, where the best animal could always win a deal more money than he could at Islington. This, however, will be no longer the case. Accumulating every possible prize he could, the total of Lord Aylesford's successes at Birmingham with his Shorthorn steer amounted to about £120; whereas, as the best of all in London, he will make up a purse of some £170. This is as it should be; and the national show would threaten no longer to be so much of a second-hand business as it latterly has been. As the offer comes more to develop, many of the best animals will probably be kept back, with a view to "the Club hundred," rather than having their bloom taken off at meetings immediately preceding the great week in London.

A combination of circumstances has told somewhat against the inauguration of this handsome premium. In the first place it was not known soon enough to ensure any especial preparation or demonstration over its award; while the uncertainty engendered by disease floating about has tendered to lessen the opportunity or encouragement

to "ripen" any very crack animals. It has thus happened that the first 100 gs. winner is by no means the best beast ever seen at the Smithfield Show. Indeed, our first run through the entries, tends in every way to confirm this impression. Nevertheless, nearly all the champion animals of the year were to be found in the Agricultural Hall: Lord Aylesford's Shorthorn steer, the best of all at Birmingham; Mr. Roland Wood's Shorthorn steer, the best of all at Oakham; Sir Walter Trevelyan's Shorthorn cow, the best of all the cows and heifers at Birmingham; Mr. Outhwaite's Shorthorn ox, the best of all the Shorthorns at Leeds; Mr. Bettridge's Hereford, the best of all the beasts at Abingdon, and Mr. Farthing's and Mr. Heath's oxen, the best of the Devon and Hereford breeds at Birmingham. In truth, wherever it well could be, the return-list of the Smithfield Club Show is more an echo of the Midlands' than might have been anticipated; for the Council have so contrived that in every section, save the Pigs, the Judges in Birmingham are represented in London. Thus, in Shorthorns we have again Mr. Sanday; in Herefords and Devons Mr. Kearey; in Southdowns and shortwools Mr. Legar, and in longwools Mr. Clarke, of Scopwicks; while of course Messrs. Sanday and Kearey take their share of duty over the other breeds and crosses. Nothing can be more impolitic than this, and murmurs grew louder and louder during the morning as the awards still went the same way. Mr. Parrington, at the best managed meeting we have,

makes it an indispensable condition that any judge who accepts office at the Yorkshire in August should not have acted at the Royal Society's Show in July; and the Smithfield Club must do the same by Birmingham.

It is not our purpose here to repeat ourselves. We give a full report of the Birmingham exhibition; while a valued correspondent, himself a breeder and a frequent judge, has favoured us with a very lengthy account of the Leeds celebrities; so that the merits of the several competitors may be easily gathered. The Show altogether, more especially of cattle and pigs, is very moderate; and the many puffs put about as to this being numerically larger than ever is simply untrue. The Devons and Shorthorns, however, make up two very creditable lots; the Sussex and Highlanders are also good; the Polled Scots and Herefords inferior; and the Crosses noticeable for some very good beasts.

In a medium class of Devon steers Mr. Hambro's clever beast is again first, while a fresh entry by Mr. McNiven drives Mr. Nixey's second at Birmingham back to the third place. In the old class of Oxen or Steers Mr. Farthing's ox is again first, but a good animal of Mr. Farquharson's beat Mr. Burton's, now third instead of second. The places of the first and second heifers were reversed in favour of Mr. Nixey *vice* Mr. Farthing; but Mr. Farthing's best cow at Birmingham was also best here; and the next two were put about without any just cause as it would so seem for the correction, as we altogether prefer Mr. Hitchcock's entry. In the class of youngest steers Mr. Buller won with a very well-bred one; and the companion display of Shorthorn steers, Her Majesty's, was pronounced to have the pick in a plain, gaudy youngster at best; but Mr. Stilgoe's second was still worse, and the class altogether a bad one. The Birmingham hero was again the first of his class, with Mr. Roland Wood's red steer again second to him, and Lord Penrhyn third, but a long way off the other two in merit. In no division did the first prize so fairly place himself as in that of Shorthorn Oxen, as Mr. Outhwaite's beast was ordered in long before the Judges had done with the others, as it was palpable thus early how superior he was, as many thus early proclaimed him the 100^gs. winner. This was the best of all the Shorthorns at Leeds, as he no question should have been the best of all; but greatly to Mr. Knowles' disgust, the other two Judges, who judged like butchers, gave Mr. McPherson's cross-bred the highest honour they had to bestow. The Marquis of Exeter was put second with a fair ox of some style, that has already been about, as has Colonel Lindsay's third—the best of his class at Birmingham, and as middling an animal as ever took a prize at a national show. Nevertheless the judges appended a couple of commendations to their award. The first and second Shorthorn heifers were first and second at Birmingham; the first and second Shorthorn cows were first and second at Birmingham, and the third there was fourth here, a fresh cow of the Duke of Devonshire's dividing her from her companions.

There were some very good Sussex steers, although the foot-and-mouth disease had kept two or three at home, and a famous Sussex cow from the Messrs. Heasman's herd, that took first prize as a yearling at the Battersea Grand National. There were in all half-a-dozen entries of Norfolk and Suffolk Polled, and they must show better to deserve their distinctive rank at The Royal. There were four Long-horns, three or four Scotch no-horns, with no Mr. McCombie amongst them; two or three Irish, and two or three Welsh beasts. The Highlanders were better with two fresh names on the prize list and Birmingham beaten. Mr. Martin's cross, that ran the Shorthorn so closely in the Midlands,

was encountered here by a very kindly-looking "nick" exhibited by Mr. Heath Harris, with a good Shorthorn head and great broad back, but not altogether the wonder his friends made him out to be. The Herefords attracted very little attention, and in the youngest class there were only two entries; while Mr. Price and Mr. Heath had again the honours of the other two classes; with Mr. Bettridge, however, twice put out for second by Lord Darnley. The positions of the two best Hereford heifers in the Midlands were now reversed, and the Hereford cows we never saw out.

Amongst the Sheep, Lord Berners' Leicesters, Sir John Rolt's Cotswolds, Mr. Byron's Lincolns, Mr. Rogers's Oxfords, and Lord Walsingham's Southdowns still tell out the old old story, for they were all firsts, last week, although of course not always with the same sheep. In the yearlings, for instance, the Merton Downs weighed two stone a sheep more than the little beauties at Birmingham, but, big or little, they had it all their own way. There was no very great entry of Shropshires, but the supporters of the Hampshire Downs seem to be coming out in more force at these meetings; and Mr. Overman sent some of his best crosses.

Mr. Foljambe, with an eye to the £100 Plate, entered his white steer amongst the Extra Stock, where Mr. Willis' famous old cow was also nominated, but was not sent. With more courage the Argentine Government sent a beast "supposed to be descended from the Spanish," that had as many faults as it is about possible for any animal to possess. Harsh, ungainly, and coarse, if this be the stuff they are about to make potted beef of, the better for the very poor who cannot afford to purchase such a luxury.

DURING THE WEEK.

A more deliberate examination of the classes only tends to confirm the opinion we have already expressed as to the moderate character of the meeting, more especially as regards cattle and pigs; while, as we said of Birmingham, after first trying the strength of the year, we doubt much if there be really a Gold Medal animal out, as the best of all can be no more than the best of a bad lot. Indeed, so evenly indifferent were the entries that another set of judges might reasonably enough, as we thought, have reversed many of the decisions. But there was not another set of judges, as almost everywhere the experience of the previous week was brought to bear, with an influence that, of course, might have been expected, and thus Ilington became more than ever a mere echo of Birmingham. The Devon and Hereford man did not certainly hold quite so strongly to his line here, but then he appeared to have no great weight in the Midlands; whereas the Shorthorn awards followed as faithfully as it was possible one show on the other. It is satisfactory, however, to hear that this duplicate system will no longer be sanctioned by the Smithfield Club, as surely they might change about a little even in Birmingham from Messrs. Sanday and Kearey.

It is not our intention to go again very minutely over the merits of animals, with which, from our own and our own correspondents' reports, the reader must be by this time tolerably familiar. As we stated last week, the Devons and Shorthorns made-up to very creditable lots, the Sussex and Highlanders are good, the Polled Scots and Herefords inferior, and the Long-horns, the Suffolks, the Welsh and Irish so short of entries as to command little attention. In the older class of Crosses there were, no doubt, more good beasts than we had allowed for, from a first look, and a general commendation was very honestly deserved. In fact, here centred the strength of the show, and could the opinions of breeders and feeders, of other judges, of salesmen and butchers have

been polled, there can be no doubt but that the first £100 would have gone by a very large majority to a cross-bred ox. Writing of the Birmingham Meeting we said "the only really formidable opponent to Lord Aylesford's steer turned up in Messrs. Martin's Aberdeen cross. This was a great square upstanding animal, of more size rather than majestic appearance; far better forward than the Shorthorn, and at his age a much more valuable beast for the butcher. He was not perfect, nor on an average a Gold Medal ox; but he most probably would have been in such a show had not two out of the three Judges been Shorthorn men." And this was the beast that the public went for at Islington, where he showed even better, if possible, than he had done during the previous week. Still he is "a two-sided" animal, very level and true from the near, but growing gummy on the off, and so seeming to show a weak place behind the shoulder. With this animal, however, the Shorthorn judges at Islington had nothing whatever to do; for notwithstanding they had one of the Birmingham men amongst them, the Devon, Hereford, and Other-breeds' bench committed the egregious mistake of placing Mr. McPherson's plain, common-looking animal before Messrs. Martin's far more taking ox; and thus the Cross-breeds were put virtually out of competition for the £100 plate. So immediately manifest was this error that one of the stewards went so far as to suggest that the other set of judges should select for themselves a better beast from the classes they had not been acting over than the one which their fellows had brought out. But this, of course, would have necessitated judging the whole of this section over again, and as this could not be admissible the way was in a great measure cleared for Lord Aylesford's steer, who had worn well, and came out still very fresh and blooming. He is certainly an animal of much style, very good to meet, and with a capital back; but, as we have already said of him, he is not thoroughly true—the more particularly forward. His head, not quite a nice one as he is hog-jawed, is badly set-on, and he is not well-covered about his shoulders. In fact a much finer specimen of the Shorthorn breed was Mr. Outhwaite's ox, which our Leeds correspondent described so fully last week, and there was no animal that won so easily in his class. But the judges made every allowance they could for early maturity, and so decided for the younger beast, although he would never promise to grow into so good an ox as the other. Writing of the Devons at Birmingham, we said, "there were this season two really good classes of oxen, that walked up from their stalls with something of the air of race-horses; as assuredly there is no beast shows so much blood as a Devon. Of the first and second in the old class and the first and second in the young class it was anything for choice, so evenly were they matched, and so close was the competition. The best *bred* and *fed* was assuredly Mr. Hambro's Delemoe, a very blood-like three-year-old, all good meat to the hand, and an admirable animal when out; while Mr. Nixey's next best in this lot was very neat and taking, but not so ripe. The judges, however, pronounced the best of all the Devons to be Mr. Farthing's oldest steer, the second in his class at the Plymouth show last Christmas, and a beast of more breed and quality than the Somerset-Devons always reach to. Then he was firm in his flesh if not so forward as he might be, and Mr. Burton's long, straight, stylish second was almost his equal, if Mr. Hambro's were not the best of the three." And at Islington, notwithstanding that Mr. Farthing's best of all the Devons at Birmingham was in the yard, the champion of the breed for £100 was Mr. Hambro's three-year-old; no question the ripest and nicest ox of his kind. If Mr. Outhwaite's was the handsomest sample of the Shorthorn males, Messrs. Mitchell's Blue Belle was still more unmistakably the

belle of her company. She shows a deal more breeding and character than Sir Walter Trevelyan's best of all the cows and heifers, and it appears that our opinion as to her "still being more an ornament for the herd than a victim to the shambles" is to be acted, on as Blue Belle returns to Alloa, there being hopes that she is in calf.

There would of a necessity be much more of the old story in going through these three established breeds; but we may just mention in passing, that Mr. Bettridge's handsome steer, the third, as he should have been second at Birmingham, is out of Nora, and not Stately 2nd, Mr. Evans having sold two steers from the Swanstone herd, to go into Berkshire. The Sussex, which make no mark in the Midlands, are rapidly improving as show stock, although their breeders quite scout the notion of their owing anything of this higher quality to the Devon. There is assuredly no variety of stock which comes more "sorry," a pretty good proof of the breed being established, and not tampered with. They would seem, however, only to feed up to a certain point, and in the capital entry of steers, one or two would have had more notice had more been made of them. It is not so long since that a Sussex stood in for the cup, and at this very meeting the Sussex and the Highlanders were the only distinct breeds of which whole classes were commended. But this, though, is saying almost too much, for the Highlanders are not a distinct breed according to the ruling of the Smithfield Club. They are the rather "Scotch-horns," and accordingly a capital class of those beautiful picturesque shaggy-coated Highlanders was disfigured by the appearance of an animal which had little or nothing of the true Highlander about him; and yet this brute, as a butcher's beast, was placed first. As a sample of anything Mr. Morrison's handsome, long, low, and sturdy mountaineer was worth a thousand of the other, which began with an ugly "cowy" half-Ayrshire head, as he is probably a cross, and where he would not have won. There is no primer beast, according to either grazier or butcher, than your true Highlander, and there is no more taking one in the show-yard, and yet the Council of the Smithfield Club refuses to allow him a rank of his own, but sorts him with mongrels, and turns the whole breed into a burlesque. Of course, an objection was lodged against Wishart and Wyalie's beast, and of course nothing came of this, as the class was open to all Scotch cattle with horns on their heads; although it is not so clear after all, his breeder being not known, and the animal itself exhibiting no particular features of any breed, how it could be passed as a Scot. A first cross for feeding has commonly an advantage over a pure-bred beast, and the present open and very unsatisfactory condition should be amended forthwith, or anything with "a crumpley horn" might on the same showing be entered amongst the Shorthorns.

With a judge straight up from Birmingham in each division, the awards in the sheep classes ran almost everywhere the same, save where occasionally an entry was absent, and inferior animals succeeded to the place. As a whole, however, the sheep here were superior to those exhibited in the Midlands, breeders like Lord Walsingham reserving their best lots, and others like Mr. Overman with his cross-breeds, holding back until they came on to London. And here the strength of the sheep show was to be found; for when the two sets of judges met to award the new £50 premium, they divided in this way—three declared for Lord Walsingham's Southdowns, two for Mr. John Overman's capital cross of a Norfolk longwool with a Southdown ewe, and one for Lord Berners' Leicesters. The Merton flock, moreover, in the actual adjudication was not only first, but second, the yearlings coming next to the old pen, and the cross-breeds being by

a majority considered "next best." As we have already said, a first cross, whether with cattle or sheep, will, of course, always tell at a fat stock show; as nevertheless, the longer the truly-bred flocks are kept pure, the more valuable will they become. The Keythorpe Leicesters have some merit in this way, although they do not quite realise the thoroughbred type of the now somewhat old-fashioned Leicester sheep. The classes here were still respectably filled, with sheep uniting good frames with coats not heavy, but fine and lustrous. The Cotswolds are apparently set down as the next "established" breed of the white faces; but the hill-men must show up stronger at our national gatherings, if they would retain their position among the first breeders of this country. Two pens, one good and one indifferent, are not calculated to carry a favourable recollection on to next year's ram sales. Of the Lincolns, again, there were only five entries; but they were heavy and good of both frame and wool, a deal of the credit for coat being apparently due to the pure Leicesters. The awards went in favour of the three same exhibitors as at Birmingham, or, indeed, for that matter, as at Lincoln in August. Still, some dissatisfaction was expressed at the placing of the first, where the sheep were too light in their coats. The Romney Marsh sheep handled as they die, well, but their peculiar features are still undisturbed by improvement, and their heads, scrags, back-bone, legs, and hair as significant as ever of their ancient and uncontaminated race. If it be not paradoxical to say so, the value of a pure-bred was admirably shown in the cross-bred long-wooled class; for here there was a pen of first-class Leicester and Lincolns, which had all the form and quality of mutton and fleece of the Leicester, while their live weight was 7 cwt. 26lbs., or heavier than one pen of the Lincolns, and nearly as heavy as some other pens of these sheep. This cross was achieved by Mr. W. D. Wootton, and a better mixture has seldom been seen. Sir W. de Capel Brooke's "nick" of the same kind, but with more Lincoln in it, was also very successful; while Messrs. Howard's Oxford-and-Gloucesters were the heaviest if not by any means the handsomest of the class.

The great pride of the show was clearly to be found amongst the Southdowns; and as we said at Birmingham, if there had been a prize for the best entry of any animals Lord Walsingham would have won it. Lord Sondes had some very good second-prize shearlings, and Sir W. Throckmorton's third pen were heavier than the first shearlings; but the style and quality of the Mertons were deservedly triumphant, as it is to be hoped we are coming to see that it is not mere weight which marks the excellence of a Southdown. The light-weights from the same famous flock were still prettier, and Mr. Foljambe and Lord Sondes quite deserving of their places, keeping to purity of type as well as to early development; but Mr. Rigden, whose stock would seem to come very capriciously was in no force, and Sussex, indeed, quite out of form. No wonder that the judges commended the class of old sheep, for never has there been one so regular and true in form after high feeding from very lambs. And here the Merton wethers reigned supreme as they deserved, for taking them all in all, for fineness of touch, broad and level shoulders, muscular backs and rumps, and "legs of mutton," they were certainly pictures to look on, and the £50 award spoke for itself.

The Hampshire or Wiltshire Downs were better than at Birmingham; and the Messrs. Russell's sheep were remarkable for the great amount of flesh of fine quality, their backs being excellent, and there was no pen better fed. The Shropshires decline in number, and as all the older breeders of note were again absent, Lord Chesham

took their pride of place with his neat and well fed pen, the pick of his Bingham winners, Mr. Nock's being again a very good second with his larger sheep. The one pen limit let in Lord Wenlock as third, Mr. Bach's, Mr. Matthew's, and Mrs. Beach's entries, for being absent. Lord Chesham made an entry of two-shears, but his young flock is probably scarcely up to this class as yet, for they were not sent; and this again gave Lord Wenlock a turn with his "faggy" coats and infirm mutton, Lord Aylesford's third best being clumsily disfigured by the shears; but the Eacrick pen had no right to beat Mrs. Beach, and the Birmingham placing was no question the sounder award. Some of the Oxfordshire Downs were also by no means improved from the wool on their backs having been cut down, while they were bedaubed with a terrible mixture, like fish oil and brown ochre. Mr. Alfred Rogers did not bring on his Birmingham pen, and although he again won the competition was much keener, with all the prize pens tracing to Mr. Charles Howard's flock. This of itself proves that uniformity and careful culling is coming to be appreciated, as perhaps no man has now a more level flock of ewes than they can show you at Biddenham.

The mountain breeds, favourites as they often are with the butcher, are not likely to wander far from their own walks, if from their picturesque appearance they tell well in the show-yard; but considering the breeders of the Dorset and Somerset horns are going in for more distinctive rank of their own, the argument they offered here was not a very strong one. In a mixed lot of Ryelands, Cheviots, Dorsets, "&c.," there were three entries for three prizes—one of Cheviots, one of Dorsets, and one of Ryelands. Then there were two pens of Exmoors, and one of Scotch mountaineers.

In the Extra Stock Lord Berners was beaten in a class for single Leicester wethers, by a sheep from Eastburn, Driffild, in which competition the great difference in the weight of each no doubt told. From the other long-wools, Mr. J. H. Casswell's sheep died last week; had this not been so, there would have been a close run between it and Mr. Harris' first cross which took the Cup.

The single Southdown wethers were very irregular, and the remarkable beauty, as well as good weight, of Lord Walsingham's, made this as easy a winner for the flock as in other classes. For ewes, however, Sir William Throckmorton took the Cup, and beat Lord Walsingham. The Cup sheep, for a short-wooled wether, not Southdown, was a Shropshire, and an admirable sheep, although of not a very heavy weight for this breed. Amongst the ewes was a wonderful Hampshire Down, for size and quality—within 8lbs. of Mr. Druce's Oxford Down wether in the males of this class, and heavier by 32lbs. than Mr. Nock's Shropshire wether. Her age, moreover, was only twenty-two months.

Mr. Overman's absence from Bingley Hall is now explained; for he evidently reserved his forces for London. This answered well, for in the cross-bred long and short-wooled sheep he took the £20 Cup as well as medal for the best pen of sheep in the Shropshires, Oxford, cross-breeds, and any other sort not specified in the prize-list. There was only one heavier pen in the class, and these were Hampshires and Lincolns, the weight of which was 7-2-18, and they were sent by Mr. Rook, of Watton, Norfolk. In the class under 220 lbs., Mr. Overman was again first, Mr. Hine, who has often been a good match for the Burnham sheep, being on this occasion nowhere.

In the pig show there was but little competition; as, in fact, in many of the classes the business was got through on the agreeable condition of all prizes and no blanks, there being in all some eighteen

premiums to be distributed amongst thirty-four pens. Of these, four or five lots were wonderfully good, and the remainder so moderate that, as the three judges at once admitted to us, they had often a difficulty in finding anything good enough to win. Still this section opened well, for Mr. Cattle's first prize white pigs, were at just nine months' old about as good a pen as ever was exhibited, and it is a nice question whether they should not have taken the Cup for "the best of all the pigs." Captain Warren's second here are sadly short of hair, and, in truth, not so good as Mr. Lynn's unnoticed entry. But the Birmingham pigs from Stroxtton did better in the next class, where they beat a very inferior entry, and were straightway objected to, though the veterinary evidence went for nothing, and the stewards had no hesitation in passing the first prize pen. As we wrote of them in the Midlands, they are light in their middles; but are otherwise very good, with capital heads for whites, as have Lord Radnor's in the next class. One of the Colehill is coarse in his coat, but the three are preferable to Mr. Dunn's first; while it is difficult to understand for what her Majesty's entry was commendable. At double the age they are just about the size and weight of Mr. Cattle's pigs, as in no other way remarkable for quality or excellence. Mr. Chamberlayne's first lot of blacks would be one of the picked pens of the show; but then in the very next class some of these same pigs are disqualified as over the stated age. Not only were the inspectors against them, but the bailiff or pigman admitted on examination that the same trio were exhibited at Southampton, and that they had dropped some thirty days in the interim. That is, according to that at which they were entered at in the summer, they were now just so much below their proper age. Mr. Benjafield's improved Dorsets, and very good pigs, succeed to the place; and Mr. Kent becomes second best with a nice level lot. The "effect" of Mr. Coote's cup pen was destroyed by one of the three dying soon after the award was made; while, smart pigs as they are, it is not so clear, as we have already intimated, that they were so decidedly the best. It depends a vast deal whether a judge have himself a black or white "fancy." The Berkshires are in no great force, and we have now a new variety in the "Bayfordbury breed," three good sorty pigs certainly; but surely there is something of an absurdity in calling every sty a breed of itself, as where is this to end? The Smithfield pig show was inferior to the Birmingham, and that is proved by second and third prize pens there reaching to first in London. Of Mr. Clark's Berkshires we then spoke as being "very long and handsome, but as hardly made up enough for exhibition or well matched, or they otherwise would at least have been second," and now they are first. The single pig which takes the medal is called a Dorset; but there are unmistakeable signs of his having been "improved" by a cross of the Berkshire. The pigs, like other sections of the show, have been terribly over-puffed by the creatures of the Agricultural Hall Company; and we thoroughly agree with the judges as to the very moderate character of the general entries in the still anything-but-salubrious swine-hole. The weights of the pigs have not been taken; but we give our prize list with the weights of all the winning cattle and sheep appended.

On Friday, the closing day of the meeting, the veterinary inspectors examined every animal in the Hall, amongst which they found no suspicion of disease. About 40 beasts were, however, on Saturday, stopped by order of the Privy Council on account of disease. Some explanation of this may be found in the following circumstances, the account of which has been given us by very good authority. The animals

from the Birmingham Show—which were forwarded in a train of 30 trucks—arrived alongside the pens containing about 800 foreign beasts, which were in the Maiden-lane Station previous to the arrival of the Birmingham train. A large number of these foreign animals were driven alongside the train which contained the beasts intended for the Agricultural Hall, and which were afterwards driven there. The close proximity into which the animals were brought was sufficiently dangerous, but things were made worse by the persons in charge of the animals from Birmingham taking the bags containing the meal and cake from the trucks, and placing them on the spot over which the foreign animals had passed. This provender was afterwards returned to the beasts, and we believe was actually forwarded to the Agricultural Hall. Our informant was an eye-witness, and took the pains to call the attention of the railway officials to the proceeding, and, to their great credit, the latter did their utmost to keep the animals separate.

JUDGES.

DEVONS, HEREFORDS, SUSSEX, NORFOLK OR SUFFOLK
POLLED, LONG-HORNED, IRISH CROSS OR MIXED.

W. H. Keary, Bridgenorth, Salop;
W. Yeomans, Stretton Court, Hereford;
John Ford, Ruahton, Blandford.

SHORT-HORNS, SCOTCH AND WELSH.

Hugh Aylmer, West Dereham, Norfolk;
Charles Howard, Biddenham, Beds;
William Sanday, Radcliffe-on-Trent, Notts.

LEICESTERS, COTSWOLDS, LINCOLNS, KENTISH OR ROMNEY
MARSH, OXFORDSHIRE, MOUNTAIN, AND CROSS.

Charles Clark, Scopwick, near Lincoln;
Ralph Newton, Campsfield, Woodstock;
Jonn. Davis, Webton Court, Hereford.

SOUTH-DOWNS, HAMPSHIRE OR WILTSHIRE, SHROPSHIRE,
RYLAND, CHEVIOT, AND DORSET.

Henry Masfen, Pendeford, Wolverhampton;
Henry Luger, Ingham, Bury St. Edmund's;
Henry Hart, Beddingham, Lewes, Sussex.

PIGS.

Joseph Smith, Henley-in-Arden, Warwick;
Richard Woodman, Southcote, Lewes;
Gilbert Murray, Elvaston Castle, Derby.

CATTLE.

The following Classes are without restrictions as to feeding, yet the kind or kinds of food must be certified. The breeder of the best entry in every class receives a Silver Medal.

DEVONS.

Steers, not exceeding 2 years and 6 months old.

First Prize of £20, to J. H. Buller, Downes, Crediton, Devon—13 cwt. 26lbs.

Second of £15, to W. G. Nixey, Upton Court Farm, Slough, Bucks—12 cwt. 2 qrs. 12lbs.

Third of £10, to Her Majesty the Queen, the Prince Consort's Norfolk Farm, Windsor, Berks—10 cwt. 3 qrs. 7lbs.

Steers, not exceeding 3 years and 3 months old.

First Prize of £30, to C. Hambro, M.P., Milton Abbey, Blandford, Dorset—14 cwt. 6lbs.

Second of £20, to C. McNiven, Perrysfield, Godstone, Surrey—15 cwt. 4lbs.

Third of £10, to W. G. Nixey, Upton Court Farm, Slough, Bucks—13 cwt. 1 qr. 14lbs.

Commended.—R. Farthing, Farrington, Somerset—14 cwt. 1 qr. 8lbs.

Steers or Oxen, above 3 years and 8 months old.

First Prize of £30, to W. Farthing, Stowey Court, Bridgewater, Somerset—14 cwt. 8 qrs.

Second of £20, to J. J. Farquharson, Langton House, Blandford, Dorset—15 cwt. 13lbs.

Third of £10, to R. Burton, Place Barton, Broadclyst, Devon—16 cwt. 8lbs.

Heifers, not exceeding 4 years old.

First Prize of £25, to W. G. Nixey, Upton Court Farm, Slough, Bucks—12 cwt. 1 qr. 4lbs.

Second of £15, to W. Farthing, Stowey Court, Bridgewater, Somerset—13 cwt. 1 qr. 12lbs.

Third of £10, to C. McNiven, Perrysfield, Godstone, Surrey—10 cwt. 3 qrs. 22lbs.

Commended.—W. Smith, Hoopers, Exeter—11 cwt. 2 qrs. 2lbs.

Cows, above 4 years old.

First Prize of £25, to W. Farthing, Stowey Court, Bridgewater, Somerset—16 cwt. 2 qrs. 5lbs.

Second of £15, to W. Smith, Hoopers, Exeter, Devon—12 cwt. 1 qr.

Third of £10, to J. Hitchcock, Broomhouse, South Molton, Devon—14 cwt. 3 qrs. 5lbs.

HEREFORDS.**Steers, not exceeding 2 years and 6 months old.**

First Prize of £20, to P. Turner, The Leen, Pembridge, Leominster, Hereford—14 cwt. 3 qrs.

Second of £15, to Her Majesty the Queen, the Prince Consort's Flemish Farm, Windsor—14 cwt. 3 qrs. 22lbs.

Steers, not exceeding 3 years and 3 months old.

First Prize of £30, to J. Price, Court House, Pembridge, Hereford—16 cwt. 3 qrs. 26lbs.

Second of £20, to The Earl of Darnley, Cobham Hall, Gravesend, Kent—17 cwt. 1 qr. 6lbs.

Third of £10, to H. Bettridge, East Hanney, Wantage, Berks—15 cwt. 3 qrs. 26lbs.

Commended.—A. Pike, Milton, Gloucester—16 cwt. 6lbs.; R. Wortley, Suffield, Norfolk—14 cwt. 2 qrs. 24lbs.

Steers or Oxen, above 3 years and 3 months old.

First Prize of £30, to W. Heath, Ludham Hall, Norwich, Norfolk—19 cwt. 6lbs.

Second of £20, to the Earl of Darnley, Cobham Hall, Gravesend, Kent—18 cwt. 3 qrs. 16lbs.

Third of £10, to H. Bettridge, East Hanney, Wantage, Berks—17 cwt. 24lbs.

Heifers, not exceeding 4 years old.

First Prize of £25, to J. H. Arkwright, Hampton Court, Leominster, Hereford—14 cwt. 8lbs.

Second of £15, to T. Garrett, Compton Scorpion, Shipston-on-Stour, Warwick—14 cwt. 2 qrs. 19lbs.

Third of £10, to R. Coston, Hayton, Stanton Lacy, Bromfield, Salop—13 cwt. 3 qrs. 20lbs.

Commended.—Her Majesty the Queen, Flemish Farm, Windsor—15 cwt. 1 qr. 6lbs.

Cows, above 4 years old.

First Prize of £25, to J. Baldwin, Luddington, Stratford-on-Avon, Warwick—18 cwt. 1 qr. 13lbs.

Second of £15, to A. Benjafield, Stalbridge, near Blanford, Dorset—15 cwt. 25lbs.

Third of £10, to R. Wortley, Suffield, Aylsham, Norfolk—14 cwt. 3 qrs. 4lbs.

SHORTHORNS.**Steers, not exceeding 2 years and 6 months old.**

First Prize of £20, to Her Majesty the Queen, the Prince Consort's Shaw Farm, Windsor—14 cwt. 1 qr. 12lbs.

Second of £15, to Z. W. Stilgo, Adderbury Grounds, Adderbury, Oxford—14 cwt. 3 qrs. 12lbs.

Third of £10, to R. E. Oliver, Sholebroke Lodge, Towcester, Northampton—15 cwt. 1 qr. 23lbs.

Steers, not exceeding 3 years and 3 months old.

First Prize of £30, to the Earl of Aylesford, Packington Hall, Coventry, Warwick—19 cwt. 2 qrs. 23lbs.

Second of £20, to R. Wood, Clapton, Thrapstone, Northampton—17 cwt. 3 qrs. 24lbs.

Third of £10, to Lord Penrhyn, Penrhyn Castle, Bangor, Carnarvon, N. Wales—20 cwt. 13lbs.

Highly commended.—T. Pulver, Broughton, Northampton—17 cwt. 2 qrs. 14lbs.

Steers or Oxen, above 3 years and 3 months old.

First Prize of £30, to J. Outhwaite, Bainesse, Catterick, Yorkshire—20 cwt. 1 qr. 6lbs.

Second of £20, to The Marquis of Exeter, Burghley Park, Stamford—20 cwt. 2 qrs. 21lbs.

Third of £10, to Col. Loyd-Lindsay, M.P., Lockinge Park, Wantage, Berks—20 cwt. 2 qrs. 12lbs.

Highly commended.—R. H. Harris, Earnhill, Morayshire—20 cwt. 2 qrs. 21lbs.; P. Brown, Glentworth, Lincoln—19 cwt. 2 qrs. 21lbs.; J. Freeman, Glapthorne, Northampton—19 cwt. 2 qrs. 23lbs.; R. Wood, Clapton, Thrapstone, Northampton—20 cwt. 3 qrs. 16lbs.

Heifers, not exceeding 4 years old.

First Prize of £25, to Col. Chas. Towneley, Towneley Burnley, Lancaster—17 cwt. 1 qr. 8lbs.

Second of £15, to T. Atherton, Chapel House, Speke, Garston, Lancashire—18 cwt. 3 qrs. 16lbs.

Third of £10, to J. B. Aylmer, Fincham Hall, Downham, Norfolk—16 cwt. 2 qrs. 2lbs.

Highly commended.—J. Reed, Graystone, Aberdeenshire—16 cwt. 14lbs.

Cows, above 4 years old.

First Prize of £25, to Sir W. Calverley Trevelyan, Bart., Wallington, Newcastle-on-Tyne—19 cwt. 15lbs.

Second of £15, to A. and A. Mitchell, Alloa, Clackmannan—16 cwt. 3 qrs. 4lbs.

Third of £10, to the Duke of Devonshire, Holker Hall, Grange, Lancashire—18 cwt. 3 qrs. 22lbs.

Highly commended.—J. Whyte, Clinterty, Aberdeen—20 cwt. 1 qr. 15lbs.

Commended.—R. Eastwood, Thorny Holme, Lancashire—17 cwt. 2 qrs. 25lbs.

SUSSEX.**Steers or Oxen, not exceeding 3 years old.**

First Prize of £20, to Lee Steere, Jayes Park, Dorking, Surrey—17 cwt. 3 qrs. 10lbs.

Second of £10, to J. and A. Heasman, Angmering, Arundel, Sussex—16 cwt. 1 qr. 18lbs.

Third of £5, to G. C. Coote, Tortington, Arundel, Sussex—15 cwt. 2lbs.

Commended.—G. Napper, Orfold, Sussex—14 cwt. 1 qr. 9lbs.; J. M. Montefiore, Crawley, Sussex—13 cwt. 2 qrs. 9lbs.

Steers or Oxen, above 3 years old.

First Prize of £25, to Lee Steere, Jayes Park, Dorking, Surrey—22 cwt. 2 qrs. 2lbs.

Second of £15, to E. Cane, Berwick Court, Lewes, Sussex—18 cwt. 3 qrs. 8lbs.

Third of £10, to J. M. Montefiore, Worth Park, Crawley, Sussex—17 cwt. 24lbs.

Commended.—J. Shoosmith, Berwick, Sussex—21 cwt. 1 qr. 26lbs.; J. Neale, Coldwaltham, Sussex—Not weighed; Right Hon. H. Brand, M.P., Lewes, Sussex—16 cwt. 2 qrs. 18lbs.

Heifers, not exceeding 4 years old.

First Prize of £20, to E. and A. Stanford, Eatons Ashurst, Steyning, Sussex—12 cwt. 3 qrs. 18lbs.

Second of £15, to Lee Steere, Jayes Park, Dorking, Surrey—15 cwt. 2 qrs. 6lbs.

Cows, above 4 years old.

First Prize of £20, to J. and A. Heasman, Angmering Arundel, Sussex—17 cwt.

Second of £15, to J. Shoosmith, Berwick, Lewes, Sussex—17 cwt. 26lbs.

Highly commended.—W. Botting, Hurstpierpoint, Sussex—18 cwt. 1 qr. 28lbs.

Commended.—G. C. Coote, Tortington, Sussex—16 cwt. 2 qrs. 9lbs.; J. Neale, Coldwaltham, Sussex—Not weighed; T. Smith, Knelle, Sussex—17 cwt. 8 qrs. 4lbs.

NORFOLK OR SUFFOLK POLLED.

Steers or Oxen, of any age.

First Prize of £15, to R. C. Symonds, Aylmerton, Roughton, Norfolk—17 cwt. 16lbs.

Second of £10, to W. Harvey, Timworth, Bury St. Edmunds, Suffolk—18 cwt. 2 qrs. 16lbs.

Heifers or Cows, of any age.

First Prize of £15, to His Royal Highness the Prince of Wales, Sandringham, King's Lynn, Norfolk—18 cwt. 1 qr. 4lbs.

Second of £10, to W. T. Mullen, Swafeld House, North Walsham, Norfolk—16 cwt. 1 qr. 4lbs.

LONG-HORNS.

Steers or Oxen, of any age.

The Prize of £10, to Sir J. Harpur Crewe, Bart., Calke Abbey, Derby—21 cwt. 2 qrs.

Commended.—W. T. Cox, Derby—17 cwt. 2 qrs. 18lbs.

Heifers or Cows, of any age.

The Prize of £10, to W. T. Cox, Spondon Hall, Derby—14 cwt. 1 qr. 14lbs.

SCOTCH HORNS.

Steers or Oxen, of any age.

First Prize of £30, to Wishart and Wyalie, Gallowgate, Aberdeen—18 cwt. 1 qr. 6lbs.

Second of £15, to C. Morrison, Basildon Park, Reading, Berkshire—18 cwt. 1 qr. 19lbs.

Highly commended.—The whole class.

Heifers or Cows, of any age.

First Prize of £15, to Sir W. Culverley Trevelyan, Bart., Wallington, Newcastle-on-Tyne—12 cwt. 8 qrs. 8lbs.

Second of £10, to R. Eastwood, Thorneyholme, Clitheroe, Lancashire—13 cwt. 3 qrs. 1lb.

SCOTCH POLLED.

Steers or Oxen, of any age.

First Prize of £30, to J. Stephen Conglass, Inverurie, Aberdeen—23 cwt. 1 qr. 7lbs.

Second of £15, to A. Longmore, Linksfield, Rattie, Banff—20 cwt. 3 qrs. 20lbs.

Heifers or Cows, of any age.

First Prize of £15, to R. Jardine, M.P. Castlemilk, Lockerbie, Dumfries—16 cwt. 6lbs.

Second of £10, to J. Reid, Greystone, Alford, Aberdeen—14 cwt. 1 qr. 5lbs.

IRISH.

Steers or Oxen, of any age.

First Prize of £10, to R. Wortley, Suffield Hall Aylaham, Norfolk—12 cwt. 2 qrs. 16lbs.

Second of £5, to W. Slipper, Catfield, Stalham, Norfolk—18 cwt. 15lbs.

Heifers or Cows, of any age.

First Prize of £10, to Lord Berners, Keythorpe Hall, Leicester—13 cwt. 1 qr. 10lbs.

WELSH.

Steers or Oxen (runts), of any age.

First Prize of £20, to H. Williams, Abercothy, Nantgaredig, Carmarthen—19 cwt. 3 qrs. 22lbs.

Second of £10, to Capt. H. Platt, Gorrddinog, Bangor, Carnarvon—16 cwt. 1 qr. 20lbs.

CROSS OR MIXED-BRED.

Steers not exceeding 8 years old.

First Prize of £25, to J. and W. Martin, Aberdeen—19 cwt. 1 qr. 26lbs.

Second of £15, to W. and J. Lawson, Meikletown, Lessendrum, Huntley, Aberdeen—17 cwt. 1 qr. 7lbs.

Third of £10, to R. Walker, Altyre, Forres, Moray—16 cwt. 1 qr. 14lbs.

Commended.—J. T. Senior, Aylesbury, Bucks—18 cwt. 17lbs.; J. Wortley, Felmingham, Norfolk—16 cwt. 10lbs.

Steers or Oxen, above 3 years old.

First Prize of £25, to J. P. McPherson, Muertan of Kinloss, Forres, Elgin—20 cwt. 8 qrs. 24lbs.

Second of £15, to J. and W. Martin, Aberdeen—24 cwt. 2 qrs. 24lbs.

Third of £10, to R. H. Harris, Barnhill, Forres, Moray—23 cwt. 2 qrs. 16lbs.

Commended.—J. Bruce, Inverquhorney, Aberdeen—18 cwt. 20lbs.

Heifers, not exceeding 4 years old.

First Prize of £20, to J. D. Allen, Pyt House Farm, Tisbury, Salisbury, Wiltshire—16 cwt. 2 qrs. 6lbs.

Second of £10, to H. L. L. Morrison, Blair Guise, Whitehouse, Aberdeen—18 cwt. 1 qr. 8lbs.

Commended.—His Royal Highness the Prince of Wales, Sandringham, Norfolk—13 cwt. 1 qr. 6lbs.

S H E E P.

LEICESTERS.

Fat Wethers, 1 year old (under 23 months.)

First Prize of £20, to Lord Berners's, Keythorpe Hall, Leicester—6 cwt. 2 qrs. 21lbs.

Second of £15, to W. Brown, High Gate, Holme-on-Spalding Moor, York—6 cwt. 2 qrs. 22lbs.

Third of £5, to B. Painter, Burley-on-the-Hill, Oakham, Rutland—6 cwt. 2 qrs.

Fat Wethers, 1 year old (under 23 months.)

Each Sheep not to exceed 230 lbs. live weight.

First Prize of £20, to Lord Berners, Keythorpe Hall, Leicester—5 cwt. 3 qrs. 7lbs.

Second of £15, to J. Newman, Harrowden, Bedford—5 cwt. 8 qrs. 4lbs.

Third of £5, to Colonel Lowther, Barleythorpe Hall, Oakham, Rutland—5 cwt. 1 qr. 20lbs.

COTSWOLDS.

Fat Wethers, 1 year old (under 23 months.)

First Prize of £20, to Right Hon. Sir J. Rolt, Oze-worth Park, Wotton-under-Edge, Gloucester—7 cwt. 2 qrs. 5lbs.

Second of £15, to J. Baldwin, Luddington, Stratford-on-Avon, Warwick—7 cwt. 16lbs.

LINCOLNS.

Fat Wethers, 1 year old (under 23 months.)

First Prize of £20, to J. Byron, Kirkby Green, Sleaford, Lincoln—7 cwt. 3 qrs. 26lbs.

Second of £15, to J. R. Caswell, Quadring, Spalding, Lincoln—7 cwt. 8 qrs. 1lb.

Third of £5, to R. N. Morley, Leadenham, Grantham, Lincoln—7 cwt. 2 qrs. 16lbs.

KENTISH OR ROMNEY MARSH.

Fat Wethers, 1 year old (under 23 months.)

First Prize of £15, to W. Burch, Rhode Court, Selling, Faversham, Kent—6 cwt. 2 qrs. 12lbs.

Second of £10, to J. Newport, Elmsted Court, Ashford, Kent—6 cwt. 1 qr. 16lbs.

CROSS-BRED LONG WOOLS.

Fat Wethers, 1 year old (under 23 months.)

First Prize of £15, to T. W. D. Harris, Wootton, Northampton—7 cwt. 26lbs.

Second of £10, to Sir W. De Capel Brooke, Bart., Geddington Grange, Kettering, Northampton—6 cwt. 3 qrs. 14lbs.

SOUTH-DOWNS.

Fat Wethers, 1 year old (under 23 months.)

First Prize of £20, to Lord Walsingham, Merton Hall, Thetford, Norfolk—6 cwt. 17lbs.

Second of £10, to Lord Sondes, Elmham Hall, Thetford, Norfolk—6 cwt. 3lbs.

Third of £5, to Sir W. Throckmorton, Bart., Buckland, Faringdon, Berks—6 cwt. 1 qr. 7lbs.

Highly commended.—Duke of Richmond, Goodwood—5 cwt. 1 qr. 15lbs.

Commended.—Earl Radnor, Coleshill—5 cwt. 1 qr. 11lbs.

Fat Wethers 1 year old (under 23 months).

Each Sheep not to exceed 200 lbs. live weight.

First Prize of £15, to Lord Walsingham, Merton Hall, Thetford, Norfolk—5 cwt. 20lbs.

Second of £10, to G. S. Foljambe, Osberton Hall, Worksop, Nottingham—5 cwt. 16lbs.

Third of £5, to Lord Sondes, Elmham Hall, Thetford, Norfolk—4 cwt. 3 qrs. 25lbs.

Highly commended.—Lord Braybrooke, Saffron Walden—5 cwt. 7lbs.

Commended.—Duke of Richmond, Goodwood—4 cwt. 3 qrs. 14lbs.

Fat Wethers, 2 years old (above 23 and under 35 months).

First Prize of £20, to Lord Walsingham, Merton Hall, Thetford, Norfolk—6 cwt. 1 qr. 25lbs.

Second of £10, to Sir W. Throckmorton, Bart., Buckland, Faringdon, Berks—6 cwt. 3 qrs. 16lbs.

Third of £5, to Earl Radnor, Coleshill, Highworth—7 cwt. 17lbs.

Highly commended.—Duke of Richmond, Goodwood—6 cwt. 3 qrs. 23lbs.

Commended.—Class generally.

HAMPSHIRE OR WILTSHIRE-DOWNS.

Fat Wethers, 1 year old (under 23 months).

First Prize of £20, to R. and J. Russell, Horton Kirby, Dartford, Kent—7 cwt. 1 qr. 11lbs.

Second of £15, to J. Walter, Bearwood, Wokingham, Berks—7 cwt. 8lbs.

Third of £5, to L. Loyd, Monk's Orchard, Addington, Surrey—6 cwt. 2 qrs. 11lbs.

Highly commended.—J. Russell, Dartford, Kent—6 cwt. 2 qrs. 19lbs.

Commended.—Class generally.

SHROPSHIRE.

Fat Wethers, 1 year old (under 23 months).

First Prize of £20, to Lord Cheaham, Latimer, Chesham, Buckingham—6 cwt. 25lbs.

Second of £10, to T. Nock, Sutton Maddock, Shifnal, Shropshire—6 cwt. 2 qrs. 23lbs.

Third of £5, to Lord Wenlock, Eserick Park, York—6 cwt. 6 qrs. 2lbs.

Fat Wethers 2 years old (above 23 and under 35 months).

First Prize of £15, to Lord Wenlock, Eserick Park, York—7 cwt. 1 qr. 24lbs.

Second of £5, to S. Beach, The Hattons, Brewood, Penkridge, Staffordshire—6 cwt. 3 qrs. 18lbs.

Commended.—Earl of Ailesford, Coventry—7 cwt. 1 qr. 21lbs.

OXFORDSHIRES.

Fat Wethers, 1 year old (under 23 months).

First Prize of £20, to A. Rogers, Bromham, Bedford—7 cwt. 4lbs.

Second of £15, to F. Street, Harrowden, Bedford—6 cwt. 3 qrs. 11lbs.

Third of £5, to S. Druce, Eynham, Oxford—7 cwt. 4lbs.

Fat Wethers, 2 years old (above 23 and under 35 months).

First Prize of £15, to A. Rogers, Bromham, Bedford—6 cwt. 2 qrs. 6lbs.

MOUNTAIN-BREDS.

Fat Wethers (of any White-faced Mountain breed, of any age.)

First Prize of £15, to W. Smith, Hoopern, Exeter, Devon—5 cwt.

Second of £10, to J. Tapp, Twitchen, South Molton, Devon—4 cwt. 3 qrs. 2lbs.

Fat Wethers (of any Black-faced or Speckled-faced Mountain-breed, of any age.)

First Prize of £15, to J. M'Gill, Rotchell, Dumfries—5 cwt. 2 qrs. 12lbs.

Second of £10, to The Marquis of Aylesbury, Home Farm, Savernake Forest, Marlborough, Wiltshire—4 cwt. 1 qr. 4lbs.

RYELANDS, CHEVIOTS, DORSETS, &c.

Fat Wethers.

First Prize of £15, to J. B. Downing, Holme Lacey, Hereford—6 cwt. 18lbs.

Second of £10, to H. Farthing, Nether Stowey, Bridgewater, Somerset—6 cwt. 3 qrs. 13lbs.

Third of £5, to J. McGill, Rotchell, Dumfries—6 cwt. 17lbs.

CROSS-BRED LONG AND SHORT WOOLS.

Fat Wethers, 1 year old (under 23 months).

First Prize of £20, to J. Overman, Burnham Sutton, Burnham Market, Norfolk—7 cwt. 1 qr. 3lbs.

Second of £15, to W. Rook, Watton, Thetford, Norfolk—7 cwt. 2 qrs. 18lbs.

Third of £5, to G. Hine, jun., Oakley, Bedford—6 cwt. 27lbs.

Fat Wethers, 1 year old (under 23 months).

Each Sheep not to exceed 220 lbs. live weight.

First prize of £10, to J. Overman, Burnham Sutton, Burnham Market, Norfolk—5 cwt. 2 qrs. 16lbs.

Second of £5, to Colonel Loyd Lindsay, M.P., Lockinge Park, Wantage, Berks—5 cwt. 2 qrs. 9lbs.

P I G S.

(The weights of Pigs not registered)

WHITE.

Not exceeding 9 months old.

First prize of £10, to C. Cattle, Wiseton Grange, Bawtry, Nottingham.

Second of £5, to Captain R. P. Warren, Worthing House, Basingstoke.

Highly commended.—Rev. J. O. Stevens, Savernake, Wilts.

Above 9 and not exceeding 12 months old.

First prize of £10, to J. Lynn, Church Farm, Stroxtan, Grantham, Lincoln.

Second of £5, to W. H. Dunn, Standen House, Hungerford, Berks.

Highly commended.—T. L. M. Cartwright, Melville, Fife.

Above 12 and not exceeding 18 months old.

First prize of £10, to W. H. Dunn, Standen House, Hungerford, Berks.

Second of £5, Earl Radnor, Coleshill, Highworth.

Commended.—Her Majesty the Queen, Windsor.

BLACK.

Not exceeding 9 months old.

First prize of £10, to T. Chamberlayne, Cranbury Park, Winchester, Southampton.

Second of £5, to J. Coate, Hammoon, Blandford, Dorset.

Commended.—J. Kent, Whyke, Sussex.

Above 9 and not exceeding 12 months old.

First Prize of £10, to T. Chamberlayne, Cranbury Park, Winchester, Hampshire.

Second of £5, to A. Benjafield, Stalbridge, Blandford, Dorset.

Highly commended.—J. Kent, Whyke, Sussex.

Commended.—C. M'Niven, Perrysfield, Surrey.

Above 12 and not exceeding 18 months old.

First Prize of £10, to J. Coate, Hammoon, Blandford, Dorset.

Second of £5, to Captain R. P. Warren, Worting House, Basingstoke, Hampshire.

Commended.—C. McNiven, Perrysfield, Surrey.

OTHER BREEDS.

Not exceeding 9 months old.

First Prize of £10, to S. Druce, Eynaham, Oxford.

Second of £5, to J. Biggs, Cublington, near Leighton Buzzard, Beds.

Above 9 and not exceeding 12 months old.

First Prize of £10, to J. Roberson, Bayfordbury Park Farm, Hertford, Herts.

Second of £5, to J. Biggs, Cublington, near Leighton Buzzard, Beds.

Highly commended.—J. Treadwell, Aylesbury, Berks.

Above 12 and not exceeding 18 months old.

First Prize of £10, to J. H. Clark, Altwood, Maidenhead, Berks.

Second of £5, to J. P. King, North Stoke, Wallingford, Berks.

EXTRA STOCK.

CATTLE.

Silver Medal and £5 prize, to the exhibitor, for the best Steer or Ox, to G. S. Foljambe, Osberton Hall, Worksop, Nottinghamshire—21 cwt. 12lbs.

Highly commended.—Her Majesty the Queen, Windsor—14 cwt. 1 qr. 20lbs.

Commended.—G. Lawson, Clynesish, Sutherland, N.B.—14 cwt. 1 qr. 8lbs.; H.R.H. the Prince of Wales, Sandringham—13 cwt. 1 qr. 10lbs.; Wishart and Wylie, Gallowgate, Aberdeen—17 cwt. 1 qr. 16lbs.; T. Bromwich, Alton, Southampton—18 cwt. 1 qr. 18lbs.; J. Overman, Burnham Sutton—10 cwt. 3 qrs. 12lbs.

Silver Medal and £5 prize, to the exhibitor, for the best Heifer or Cow, to J. Christy, Boynton Hall, Chelmsford, Essex—16 cwt. 1 qr. 18lbs.

Highly commended.—R. Jardine, M.P., Castlemilk, Dumfries—9 cwt. 1 qr. 27lbs.

SHEEP.

Silver Medal, to the exhibitor, for the best Leicester Wether Sheep, to The executors of F. Jordan, Eastburn, Driffield, York—2 cwt. 1 qrs. 19lbs.

Silver Medal, to the exhibitor, for the best Leicester Ewe, to W. Brown, Highgate, Holme-on-Spalding Moor, York—2 cwt. 2 qrs. 17lbs.

Silver Medal, to the exhibitor, for the best Long-woolled Sheep (not Leicester), to T. W. D. Harris, Wootton Northampton—2 cwt. 1 qr. 12lbs.

Silver Medal, to the exhibitor, for the best Southdown Wether Sheep, to Lord Walsingham, Merton Hall, Thetford, Norfolk—1 cwt. 3 qrs. 26lbs.

Commended.—Class generally.

Silver Medal, to the exhibitor, for the best Southdown, to Sir W. Throckmorton, Bart., Buckland, Faringdon, Berks—2 cwt. 10lbs.

Silver Medal, to the exhibitor, for the best Short-woolled Wether (not Southdown), to T. Nock, Sutton Maddock, Shiffnal, Salop—2 cwt. 1 qr. 22lbs.

Silver Medal, to the exhibitor, for the best Short-woolled Ewe (not Southdown), to J. Rawlence, Bulbridge, Wilton, Salisbury, Wiltshire—2 cwt. 2 qrs. 26lbs.

Commended.—J. Treadwell, Aylesbury—2 cwt. 3 qrs. 25lbs.

Silver Medal, to the exhibitor, for the best Cross-bred Sheep (Long and Short-woolled Cross) to J. Overman, Burnham Sutton, Burnham Market, Norfolk—2 cwt. 1 qr. 8lbs.

PIGS.

Silver Medal, to the exhibitor, for the best Pig, to C. McNiven, Perrysfield, Godstone, Surrey.

Highly commended.—Captain R. P. Warren, Basingstoke; J. Roberson, Hertford.

Commended.—T. Chamberlayne, Winchester; J. Overman, Burnham Sutton; Rev. J. O. Stephens, Marlborough, Wilts; J. Coate, Blandford, Dorset.

SILVER CUPS.

A Silver Cup, value £40, to the exhibitor, for the best Steer or Ox in any of the classes, to the Earl of Aylesford, Packington Hall, Coventry, Warwick—19 cwt. 2 qrs. 28lbs.

A Silver Cup, value £40, to the exhibitor, for the best Heifer or Cow in any of the classes, to Sir W. Calverley Trevelyan, Bart., Wallington, Newcastle-on-Tyne—19 cwt. 15lbs.

A Silver Cup, value £20, to the exhibitor, for the best pen of Leicesters, Cotswolds, Lincoln, Kentish, or other Long-woolled breed, in any of the classes, to Lord Berners, Keythorpe Hall, Leicester—6 cwt. 2 qrs. 21lbs.

A Silver Cup, value £20, to the exhibitor, for the best pen of one-year-old South Downs, Hampshire, or Wiltshire Downs, to Lord Walsingham, Merton Hall, Thetford, Norfolk—6 cwt. 17lbs.

A Silver Cup, value £20, to the exhibitor, for the best pen of Shropshire, Oxfordshire, Cross-bred, or any other breed of Sheep (not specified in the prize list) in any of the classes, to J. Overman, Burnham Sutton, Burnham Market, Norfolk—7 cwt. 1 qr. 8lbs.

A Silver Cup, value £20, to the exhibitor, for the best pen of Pigs in any of the Classes, to J. Coate, Hammoon, Blandford, Dorset.

CHAMPION PRIZES.

A Piece of Plate, value £100, to the exhibitor of the best Beast in the Show, to the Earl of Aylesford, Packington Hall, Coventry, Warwick—19 cwt. 2 qrs. 23lbs.

A Piece of Plate, value £50, to the exhibitor of the best pen of Sheep in the Show, to Lord Walsingham, Merton Hall, Thetford, Norfolk—6 cwt. 1 qr. 25lbs.

A Piece of Plate, value £10, to the exhibitor of the best single Sheep in extra stock, to W. Brown, Highgate, Holme-on-Spalding Moor, York—2 cwt. 2 qrs. 17lbs.

THE IMPLEMENTS.

This department appears to be increasing in interest every year. So much is this the case that the entrance of anything which is not of a really agricultural character is prohibited by the authorities. So rigidly is this carried out, that Messrs. Aveling and Porter's steam roller for roads—with which farmers certainly have much to do—was not considered to be admissible; and coming down to smaller matters, Bradford and Co. stood among their churns and weighing apparatus, although their specialities are "Vowel" and other oddly-named washing machines. The number of stands, as compared with last year, was in 1868, 192, and this year 208, which were divided into 31 on the ground floor and 177 on the galleries.

Taking the catalogue as it runs, we find on the first stand a combined tubular and corrugated boiler, in which the water is held in horizontal and perpendicular pipes and in corrugated "tubes," each with three "lobes," the water being free to circulate through small apertures inside between the indentations, which are constructed so as not quite to meet. These water spaces between the three cylinders are stayed, to prevent the sides from collapsing. The object of this boiler is to prevent accidents from bursting, as well as to economize fuel, which it is said to do in consequence of the fire passing around the water in the tubes instead of through a body of water in which tubes are placed. This is a specimen boiler made by Kinsey, Norton, Hill, and Co., of Nottingham, and for it they claim great advantages. Messrs. Howard, of Bedford, have applied this principle of passing the heat around water instead of through it for upwards of two years. Their boiler is, however, a uniform system of

perpendicular tubes inserted into horizontal pipes. These joints were originally formed by dropping one pipe into the other, the matrix being furnished with an India-rubber ring to prevent leakage. This plan, however, has been abandoned, for the tubes are now made of wrought iron and the joints are formed by the upright pipes being screwed tightly into the horizontal tubes. The principle of heating and economizing fuel is of course the same as described in connection with Messrs. Kinsey and Co.'s boiler. Which, however, is the more efficient remains to be decided by actual experiment. Besides these tubular and combined tubular and corrugated surface boilers, we are informed that one on the same principle, but of American invention, has recently been introduced. Robey and Co., of Lincoln, exhibited a traction portable and vertical boiler, to which is fitted a patent "governor" for regulating the flow of steam to the cylinder, whereby the highest amount of power according to the pressure in the boiler is obtained. This "governor" is placed in the crank shaft, and works horizontally upon the eccentric direct. Messrs. Garrett and Sons, Leiston, keep even with the times, and show some very elegant and effective self-moving steam-engines with the farm machinery which they are intended for drawing and driving.

A striking novelty, which is as admirable for its simplicity of construction as for its effective working, is added to Messrs. Hornsby and Son's reapers and mowers. This is for throwing the cutting parts of the machine in and out of gear. It consists in a light and elegant drop catch attached to the side of the shaft; this catch falls into, and holds in its place, the eye of a light rod which runs to the gearing. By this apparatus the man using the rake may keep both hands to that implement, and merely by a triding motion of his foot throw the gearing in or out, as may be necessary. Like all simple and effective mechanical contrivances, it seems to be strange that this or some similar application has not been adopted before.

Passing by Messrs. Barrows and Stewart's and Messrs. Tucker and Sons' stands, with the only remark, viz., that the former firm exhibited some highly-finished work in steam engines and other articles, and that the sound work of the latter in engines, combined machines, and dressing machines, need no comment, we come to Messrs. Tuxford and Son's, of Boston, in connection with whose stand there are some facts for comment. The elegant donkey, pony, one-horse, and other engines of this firm are well known for their chocolate colour, fine proportions, and finish. But it is not with the quality and efficiency of engines and machines with which we here have to do, for our views are now carried around the Cape, past Hindostan, and on to the port of Peking in the Chinese Empire. By some skilled diplomacy the Messrs. Tuxford succeeded during the present year in getting introduced into that country, which was until recently a "closed nation," several of their smaller engines, and also some two-horse and three-horse engines. Last year, or within a recent period, this international trading would have been an abomination to the Celestials, and the venturesome trader who had taken such a liberty with them would have enjoyed, supposing he was caught in the fact, practical experience of the manner in which decapitation in China is performed with the sword at one blow. Not only, however, did Messrs. Tuxford's English agents get through the attempt to introduce these engines, but they succeeded in turning the event into one of festivity and rejoicing. These engines were not only passed through the Imperial Chinese Customs at the port of Peking, but they were received with military honours to no less an extent than a salute of twenty-one Imperial guns! In the meantime, the engines were set to work, and chaff-cutters, mills, and other machinery were driven

in working order, to the great astonishment, and in some cases disgust, of the natives. In the present dull state of the home trade this is a charming event for English agricultural engineers, for which reason we have devoted some length to relating its main points. Some of these engines, and mills, were purchased by the Chinese Government, and others were taken by public officials high in authority.

John Fowler and Co. had their usual stand—*excepting steam-ploughs!* A cultivator with wings for working 16 feet wide was shown; and where land has been once broken up, this machine will certainly shift it again at a considerable rate per hour or day, if it be drawn four or five miles an hour. Their traction-engines were models of taste and skill, and the remarkable strength according to weight which is given them by the steel saddle for carrying the driving-shaft and gearing is not less valuable than the design of these saddles is elegant. The winding-drum, too, is now driven direct from the crank, at the end of which is fixed the bevel gearing for driving the spindle. In minor matters we may mention effective sand caps and collars now used on wheels, and a lubricator for regulating the flow of oil according to speed, which is a recent invention of one of their mechanics.

The Messrs. Clayton and Shuttleworth have too good a standing in their specialities to care for novelties. Their stand, however, was most imposing; and Mr. Burrell's, of Thetford, which was next, was quite up to its usual excellence.

On Messrs. Howard's stand we found a novel application of a band-break to a horse-rake, whereby the rake was made so far self-acting, that a few pounds pressure on a lever to tighten the band, which encircles the box of the wheel, causes the teeth to rise rapidly for emptying themselves. On this stand there was also the tubular boiler above referred to, and the usual stock of Messrs. Howard's famous implements which have so long been before the public.

An improved knife-connecting rod, working on a steel bar in the centre of the reaper, is shown by the Beverley Waggon Company. This is so much simpler than the usual appliances, that this Company can now reduce the price of their reapers £5. A self-acting reaper was also shown.

The stand of Messrs. Ransomes, Sims, and Head need but little description, as the character of their general articles and specialities is so well known, that to enter into details would detract, rather than not, from their world-wide reputation. Two grubbing tines attached to one of their strong ploughs is, however, a serviceable application for many purposes, or when the subsoil wants moving and not turning uppermost.

Other firms of more local celebrity, whose manufactures are so well known that they would not be made more popular if discussed at length, will be found in a list below as having been present with their usual stand. Ascending the gallery we come almost at once upon Walter A. Wood's unsurpassed American mowers and reapers; and as these are now made in light iron frames, they are as attractive to look at as they are effective in the corn or grass field.

Messrs. Amies and Barford were just round the corner, "going with the sun," and here they exhibited a model, one-third size, of Campain's self-acting anchor for steam cultivation. Amongst its merits over other anchors is one which consists in its being self-moving when a simple catch is raised from one of the four notches in a disc at the end of the tumbling bar. This process is simply as follows: The hind bar of the frame is made for revolving; on each side of this bar are fixed two or three tines which point into the ground as the anchor proceeds and the shaft turns. As one set of tines enters, the other is working out and rising to come round again in turn. If four

needles be stuck sidewise through a cork, and another be passed through from end to end, and an attempt be made to press this cork and needles over a soft surface, by pressing it forward with two fingers on the top, the powerful effect of this anchor may be subsequently imagined. Two or three times are used, according to the hardness or the softness of the soil, and their length or "pitch" is regulated for suiting similar conditions. As this anchor is drawn forward by the rope which draws the cultivator, working round a pulley in the centre, half the draught is forward and half sideways, or the whole of the draught is towards the corner, which is next the plot of land to be worked. This divided forward and side draught or pressure towards one corner is the explanation as to why so insignificant looking an apparatus is capable of preserving its position when so lightly weighted against the full working power of a ten or twelve horse engine. Mr. Campaign, who is a practical farmer, and knew what value this anchor would be if he could get it to work, calculates that a very large saving of labour will be practicable with this anchor, and, also, that more work can be done per day by 10 per cent., as none of the delays occur which often happen to the common anchor. Indeed, only the same number of hands is now required to work the round-about system with this anchor, as is required for the direct system.

A notice of some other inventions and improvements want of space compels us to defer. The following is a complete list of the exhibitors:—

DOWNSTAIRS DEPARTMENT.

KINSEY, NORTON, HILL, AND CO., Nottingham.—Six and eight-horse power horizontal and vertical steam engines; improved saw bench; and Kinsey's patent twelve-horse boiler.

BOBEY AND CO., (Limited), Lincoln.—Eight-horse power traction steam engine; four and six-horse power vertical engines on patent "field" boilers; thrashing and finishing machine; straw elevator; and improved corn mill.

WALLIS AND STEVENS, Basingstoke.—Eight-horse power portable engine; four-horse power colonial thrashing machine; combined finishing and thrashing machine; patent corn screens; sets of harrows; gear plough; and spherical bearings.

GARRETT AND SONS, Leiston Works, Saxmundham.—Improved eight and ten-horse power self moving agricultural steam engine; six, seven, and eight-horse power improved portable agricultural steam engines; ten-horse power steam cultivating engines; six and eight-horse power thrashing, dressing, and finishing machines; Haye's straw elevator; improved continuous iron framed stone grinding mill; Suffolk lever corn and seed drills; fore-carriage drill steers; lever horse hoes; manure drills and distributors; field and barley rollers; lever dragrakes; chaffcutters; corn winnowing and dressing machines; and improved rick and grain ventilators.

HORNBY AND SONS, Grantham.—Eight-horse power patent portable steam engine; combined thrashing machines; governor and progress self-raking reapers; "Paragon," "Premier," "Manchester" mowers; and combined; mowers and reapers; rotary corn screen, turnip cutters, root pulpers; "Excelsior" turn-wrist and other ploughs; improved dressing machines, and reaper knife, holders and sharpeners.

BARROWS AND STEWART, Banbury.—Eight-horse power portable steam engine; drum thrashing machine, with Penny's screw; 4ft. 6in. cattle crib; india rubber and leather endless driving bands; and lever and screw lifting-jacks.

TASKER AND SONS, Waterloo Iron Works, Andover.—Six and eight-horse power portable steam engines; combined thrashing machines; corn dressing machines; and model of patent straw elevator.

TUXFORD AND SONS, Boston.—One, two, three, four, and ten-horse power improved horizontal cylinder portable steam engines; ten-horse power patent house-steeped engine, with two cylinders; combined thrashing and dressing machines; and improved centrifugal pumps.

FOWLER AND CO., Steam Plough Works, Leeds.—Ten and fourteen-horse power steam-ploughing engine; eight-horse power traction engine, on springs; turnip harrow, for steam work; and cultivator.

CLAYTON AND SHUTTLEWORTH, Lincoln.—Eight-horse power portable steam engine; ten-horse power double-cylinder engine; ten-horse power double-cylinder traction engine; four-horse power "self-contained" and horizontal fixed engines; finishing-thrashing machines; improved saw-bench and boring apparatus; complete "self-contained" double corn mill; Gillyatt's patent two-row combined liquid-manure and turnip drill; sets of adjusting blocks; sack-lifting harrows; lifting jacks; and rolled-steel beater plates.

NALDER AND NALDER (Limited), Chillow Iron Works, Wantage.—Combined finishing-thrashing machine.

BURRELL, St. Nicholas Works, Thetford.—Eight and twelve-horse power single-cylinder traction engines.

UNDERHILL, Newport, Salop.—6-horse power finishing-thrashing machine; patent elevator and corn dresser; wrought-iron cultivator; ploughs; shaft-side delivery for manual-delivery reapers; chain corn drill; cheese press; and horse rake.

HUMPHRIES, Pershore.—Combined double-blast finishing-thrashing machine.

HOWARD, J. AND F., Britannia Iron Works, Bedford.—Twelve-horse power steam ploughing and traction engine, with cultivator and apparatus complete; set of patent steam-cultivating apparatus complete; sets of patent steam harrows; assortment of Champion, Anglo-American, double-furrow, rigging, and other ploughs; sets of sig-zag, drag, chain, and jointed harrows; horse rakes; patent haymakers; moving machines; self-acting delivery reaper; sets of whippletrees; and patent safety boiler.

HOLMES AND SONS, Prospect Place Works, Norwich.—Nine-horse power double-speed traction engine; eight-horse power prize portable steam engine; combined finishing and single-winner thrashing machines; seed sheller; circular-saw table; large and small corn dressers; corn, seed, and manure drills; barley hummeller; manure distributor; and corn and seed sowing machines.

THE BEVERLEY IRON AND WAGON COMPANY (Limited), Beverley.—"Royal Leicester" prize self-cleaning clod-crushers and field-rollers; new one, two, and three-horse reapers and mowers; "Royal Newcastle," "Leeds," "York," and "Plymouth" prize one and two-horse carts, with harvest ladders, frames, raves, shelving, &c., complete; liquid-manure distributors and water and manure carts; "Royal Plymouth" prize waggon for three or four horses; lorry, drag, or rully, with patent axles; sets of patent waggon and cart wheels and axles; prize double-roller bone mills; portable farm-railway and trucks; root crusher; turnip cutter; and new oilcake breaker.

TURNER, E. R. AND F., St. Peter's Iron Works, Ipswich.—Four, five, six, seven, eight, and 10-horse power portable steam engines; thrashing, winnowing, and dressing machines for four, five, six, seven, and eight-horse power, with steam engines; corn, seed, and malt-crushing mills for hand, horse, and steam power; bean and malt mills, portable grinding mills, oilcake breakers, chaff-cutters, gear work for pony, and horse power with intermediate motion; and maize and Indian corn sheller.

AVELLING AND PORTER, Rochester.—Twelve-horse power (nominal) winding engine for steam ploughing; eight-horse power agricultural locomotive engine; and travelling rope-porter.

EDDINGTON, A. AND W., Chelmsford.—Improved twelve-horse power steam traction, ploughing, and draining engine; seven-horse power portable engine; water and liquid manure cart; pump with hose, &c., complete, and patent strap fasteners.

ALLCHIN AND SON, Globe Works, Northampton.—Three and six-horse power portable steam engines; assortment of coils of improved India-rubber cotton endless driving-bands and suction hose; leather driving bands; and set of six iron screw jacks for portable engines and machines.

RANSOMES, SIMS, AND HEAD, Ipswich.—Two eight-horse power portable steam engines; portable steam finishing-thrashing machines; patent rotary self-cleaning adjustable corn screen; assortment of Newcastle and Leicester patent prize ploughs for every description of work; Biddell's patent bean cutters and mills; improved oilcake breakers; root pulpers; single and double-action turnip-cutters; and Biddell's patent Cam and other chaff-cutters.

ASHBY AND JEFFREY, Stamford.—Two, four, and six-

horse power vertical and portable steam engines, complete; "Palmerston" haymaking machine, improved extra large horse rake, patent wheel hand rakes; assortment of chaff-cutters, for hand, horse, and steam power; bean, oilcake, and stone grinding and crushing mills; single and double-action turnip-cutters; root pulpers; pair of wrought iron wheels and axles; rotating harrows; and pony, mule, or donkey rakes.

WOODS, COCKSLEDGE, AND WARNER, Suffolk Iron Works, Stowmarket.—One, two, three, four, six, and seven-horse power vertical steam engines; assortment of corn-grinding, universal roller, crushing, bean, pea, malt, linseed and other mills, for hand, horse, and steam power; patent root pulpers for hand or horse power; single and double-action turnip-cutters; chaff-cutters, oilcake breakers; one, two, and four-horse gear; two-horse portable thrashing machine; horse-power water pump; barley aveller; agricultural saw bench; weed extirpator; improved general purpose and other carts, complete; asphaltum apparatus; and patent hog troughs.

RUSTON, PROCTOR, AND CO., Lincoln.—Two-and-a-half, eight, ten, and twelve-horse power single and double cylinder portable steam-engines; four and six-horse power vertical steam-engines; thrashing and finishing dressing machine, patent straw elevator, corn grinding mill, Woodford's patent centrifugal pump, and circular self-acting saw benches.

THE READING IRON WORKS (Limited), Reading.—Twelve-horse power double cylinder portable engine; three, six, and eight-horse power portable engines; eight and twelve-horse power fixed engines; combined finishing-thrashing machines; circular saw bench, with boring apparatus; "clipper" mowing machine, with reaping attachments; improved lever horse-rake, corn drills, patent gear for horse power, chaff-cutters, crushing and oilcake mills, and broadcast seed machine.

MARSHALL, SONS, AND CO., Britannia Iron Works, Gainsborough.—Six and eight-horse power portable steam-engines, eight-horse power horizontal fixed engine, three and four-horse power vertical engines, thrashing and finishing-dressing machines, improved grinding mills for steam power, circular saw benches, screw-jacks, cranes, and set of adjusting blocks.

GIBSON, P. AND H., Wantage, Berks.—A portable combined thrashing machine.

BROWN AND MAY, North Wilts Foundry, Devizes.—Two-and-a-half and eight-horse power portable steam-engines.

CROSSKILL AND SONS, Beverley.—Improved clod-crushers and field-rollers; strong and light general work, pony, harvest, and liquid manure carts; improved three ton pair-horse waggon, twenty-five and thirty cwt., wheels and axles, Bell's three-horse reaping machine, single and double roller, bone mills, farm portable railway and trucks, pig troughs, and root crusher.

TIZ, St. Marks' Iron Works, Lincoln.—Single and double mills, smut machine, millstones, and mill utensils.

THE GALLERIES.

WILLIAMS AND CO., London.—Patent "Archimedeon" lawn mowers.

HOOPER AND CO., Covent Garden.—Seed potatoes.

PERCE, London.—An assortment of barrows and garden engines, pumps, corn bins, cattle troughs, chaff-cutters, and general farm, domestic, and dairy utensils.

PERRY AND CO. (Limited), Lincoln.—Flour-dressing machine, adjustable rotary corn-screens; malt, lime, gravel, and coal screens, sack lifters, and rolls of galvanized wire netting.

GIBBS AND CO., Half-moon-street, London.—Collection of dried natural grasses; specimens of approved kinds of wheat, barleys, and oats in the ear; growing samples of meadow and lawn grasses; collection of agricultural seeds generally; and large assortment of agricultural roots.

ARNOLD AND SONS, London.—Varied assortment of veterinary instruments and utensils.

WHEELER AND SON, Gloucester.—Collection of roots and seeds.

HARDON, Manchester.—Samples of condimental food and patent cake.

GIBBS AND CO., Down-street, London.—General collection of agricultural roots, dried grasses, wheats, barleys, oats, and various agricultural seeds.

UNITED, London.—Model of thirty-load rick-cloth; assortment of waterproof cart, load, and other cloths; samples of sacks, nose-bags, halters, and reins, netting, and rope; and model of marquee for agricultural shows.

DAY, SON, AND HEWETT, Baker-street, London.—A large collection of stockbreeders' medicine chests and medicines essential for ready use in the farm-yard and stable; and pamphlet essays on "Farriery," "Breeding and Management of Sheep," "Rearing of Calves," and "Milk Fever in Cows."

RAYNBIRD, CALDECOTT, BAWTREE, DOWLING, AND CO., Basingstoke.—Collection of agricultural seeds, roots, grasses, feeding stuffs, and artificial manures.

WRIGHT AND SON, Great Bentley, Essex.—Samples of agricultural seeds, roots, and grasses.

ALWAY AND SON, London.—Improved milk cooler, variety of churns, and general dairy utensils.

DUFFIELD, London.—Variety of butter prints, beaters, knives, and moulds for private or dairy use.

WHITE AND CO., London.—Patent artificial dams, for feeding foals, calves, or lambs; assortment of oil-feeders, lubricators, and save-all oil-cans.

FOX AND CO., London.—Rolls of galvanized wire netting for various service; cattle, poultry, and ornamental fencing; screens, sieves, water-tanks, and liquid-manure pump.

BELLAMY, Millwall.—Wrought iron painted and galvanized cisterns, to hold from fifty to six hundred gallons; corn bins, cattle troughs, wrought iron cart bodies, funnel for engine use, and galvanized oil tank for engine use.

BEACH & CO., Dudley.—Farinaceous food for cattle, sheep, and pigs; and condiment for horses.

CORBETT, Shrewsbury.—Bury prize patent "Eclipse" winnowing corn dressing machines, and model of sheep rack.

CRANSTONE, Hemel Hempstead.—Portable grindstones for reaper knives.

DAVIS, London.—Samples of new cattle food, and compressed forage, bran, and hay.

ARMSTRONG, Penrith.—Sets of light, heavy land, and general purpose harrows.

LARKWORTHY & CO., Worcester.—One and two-wheel iron ploughs; sets of patent "Excelsior" drags and harrows, wrought iron cattle cribs, and combined racks for feeding sheep.

ALLNUTT, London.—Copies of "Estates Gazette" newspaper, and specimens of books, &c., relating to agricultural subjects.

VALLANCE, Greenwich.—One-horse power gas-engine.

THE AGRICULTURAL AND HORTICULTURAL CO-OPERATIVE ASSOCIATION (Limited), Manchester.—Samples of linseed and other cakes, artificial manures, and agricultural seeds; cattle, sheep, and poultry fencing; sets of improved wrought iron hurdles, and wrought iron farm gate.

CORBETT & SON, Wellington, Salop.—Prize two-and-a-half horse power vertical oscillating steam engine; hand and power grinding mills, pulpers, turnip cutters, and chaff cutter.

DODGE, London.—Assortment of india rubber bolts, machine bands in various lengths, suction hose, waterproof covers, asphalt roofing felt, and greenhouse and garden hose pipes and fittings.

THE DRIFFIELD AND EAST RIDING PURE LINSEED CAKE COMPANY (Limited), Driffeld.—Samples of pure linseed cake.

EAGLES, London.—Four-horse combined vertical boiler and engine; one, two, and three-horse horizontal engines, and patent epicycloidal pulley-blocks.

FERGUSON, London.—Slate cattle-trough, manger cistern, and milk cooler.

ATMOSPHERIC CHURN CO., London.—Clifton's patent atmospheric churn in various sizes, patent milk coolers, revolving milk racks, enamelled iron milk pans, and other dairy utensils; and Talbot's specific mixture for sheep, lambs, and calves.

COOKE AND CO., Lincoln.—New patent colonial and general purpose ploughs, and assorted share ploughs.

THE GUTTA PERCHA CO., London.—Gutta percha bands in various widths for agricultural machines, tubing and suction hose, shovels, probangs, buckets, measures, watering-cans, and carbons.

BROWN AND CO., London.—Samples of oil-feeders, lubricators, belt-fasteners, stable lanterns, and lubricating oils.

HARRISON AND SON, Leicester.—Collection of agricultural roots, grass seeds, agricultural seeds, dried natural grasses, various kinds of potatoes.

LYON, London.—Machines for pulping roots, and for eating meat and biscuits; churns for making from two to ten pounds of butter.

EDDINGTON AND CO., London.—Tarps, canvas, and waterproof waggon and cart covers; driving bands, sheep netting, sacks, and nose-bags; and samples of guano, artificial manures, wheel grease, and engine oils.

CARTER AND CO., London.—Specimens of agricultural roots, seeds, and grasses.

HARE AND CO., London.—Specimens of electro-printing blocks for illustrating catalogues, and case of proofs of illustrations.

EDGINGTON, London.—Cart, waggon, and rick tarpaulins and cloths, nose-bags, sacks, garden netting, &c., and model of marquee for agricultural or other shows.

KING, Coggeshall, Essex.—Agricultural roots.

KING, London.—Canvas and other hay covers, stable cloths, sacks, waggon, and cart sheets and covers, leather head stalls, and horse clothing, netting, sheep-washing aprons, and canvas horse and cattle cradles.

SUTTON AND SONS, Reading.—Large collection of natural grasses, agricultural roots, and seeds, potatoes, carrots, turnips, and onions, suited to garden or farm cultivation.

OWENS AND CO., London.—Improved double-action steam pumping engine; Bernay's patent centrifugal pumps; collection of pumps for domestic use; cart and manure pumps, Caseobury garden engine, and extinguisher; farm fire engine; boring tools, hydraulic ram, and set of model rams.

COTTAM AND CO., London.—General collection of stable fittings and utensils, and model of stable.

HANCOCK, F. AND C., Dudley.—Various sizes of Hancock's patent machines for purifying butter for domestic and dairy use.

CULLINGFORD, Stratford.—Rolls of cocoa-nut fibre and hemp, sheepfolding and garden-net, wire netting, waggon cloths, and poultry fencing.

TINKLER, Penrith.—Patent churns to make from ten to forty lbs. of butter.

BURNBY AND CO., Millwall.—Wrought-iron cisterns to hold from one hundred to six hundred gallons; wrought-iron water and manure cart bodies; wrought-iron cattle troughs; movable trough on wheels; strong hog trough; and strong corn bins.

WEIR, London.—Farmer's patent cooking boiler, fitted with steamer for potatoes, roots, &c.

BARTON, London.—Portable stable, and sets of stable fittings and utensils.

HANCOCK, Birmingham.—New haymaking machine, new horse clipper, and machines for purifying butter.

COULTAS, Grantham.—Prize general purpose corn liquid manure, root, and mangold drills.

BALL, North Kilworth.—One-horse cart for general purposes.

TREE AND CO., London.—Cattle ganges, farmers' slide rules, draining levels, barometers, thermometers, horse standard, and horse clipper.

FARDON, Leighton Buzzard.—Six-horse power horizontal steam-engine; one-horse power "Vandyke" thrashing machine; steorage drills, chaff cutters, Turner's patent cultivator, ploughs, and oilcake mill.

GILBERT, Shippin, Berks.—Eleven-row improved Suffolk corn drill, with seed-box to attach.

NEIL, HARRISON, AND CO., London.—"Eureka" smut and separating machine, and "Excelaior" bran duster.

NORTON, London.—Norton and Bowyer's patent wheat cracker; Mortlock's millstone, dressing, and levelling machines; Norton's Abyssinian tube well and pump complete; and Hawksley's patent cottage pump.

POWIS, London.—New patent endless band sawing machine, complete.

WINDER, Farningham.—Machine for folding sheep, where netting is used, with iron standard, extra roller, and wooden trough for tarring the netting.

TRIGHER AND SMITH, London.—Patent circular rick-cloth or cover.

TRELOAR, London.—Netting, stable brushes, nose bags, mats, rick and cart covers, and cocoa-fibre manure.

LOYD AND SONS, London.—Flour dressing mills for hand, horse, and steam-power; corn crushers, corn and linseed grinding mills, drug mills, and portable corn grinding mills.

BROWN AND CO., London.—New lawn mowers in various sizes; galvanized wire netting for cattle, sheep, poultry, &c.; ornamental and garden trellis wire and portable fencing; wrought iron hurdles, iron standards, and straining pillars.

CORNER AND CO., Barbridge Works, near Nantwich.—Chaff-cutting machines for hand and power.

WILDERSTIN, Elsworth, Cambs.—New patent self-acting horse rake; and improved lever cultivator, scarifier, and grubber combined.

PARHAM, Bath.—Specimens of strained wire fence, with standards and straining pillars, pairs of wrought iron ornamental and park gates; ornamental railway for park or lawn, and model of improved iron orchard house.

HUGHES AND SONS, London.—Specimens of French runner mill and bed stones; smut machine, provers, stone staff, brushes, blocks, corn measures, sack barrows, driving bands, wire, lifting jacks, mahogany and cylinder grindstone and frame, lard oil, oil feeders, and other mill necessities.

PRENN, Braintree.—Root pulpers and graters, oilcake breaker, chaff-cutter, ploughs, hoe, and round p g troughs.

DENTON, Wolverhampton.—Assortment of chain harrows, patent adjustable harrow, disc roller, and vice for reaper knives.

LANE, London.—Two-and-a-half, four, and six-horse power steam engines, with fly-wheel complete.

HERBERT, London.—Variety of weighing machines and scales, suitable for farm service; sets of weights, sets of corn and seed measures, sack barrows, knives, choppers, and axes.

TANGY BROTHERS AND HOLMAN, London.—One, two, four, and six-horse power horizontal high-pressure steam engines, "Special" steam pumps, and bundle of improved steam suet lubricators.

HEAD, WRIGHTSON AND CO., Stockton-on-Tees.—Moore's patent pulley blocks and chain.

ROSEB, F. AND G., London.—Samples of stable-pavings, bricks, tiles, garden border edgings, drain traps, sinks, roofing for farm buildings, and agricultural drain pipes and tiles.

SMITH, Foston, near Hull.—Patent self-feeding sheep rack, and improved hay rack.

JOHNSTON, London.—Butter churns, to make from one to thirty pounds, milk pails and pans, and other dairy utensils.

SPRATT, J. AND CO., London.—Samples of pure fibrine biscuits for dogs and horses, and farina meal for horses, sheep, and pigs.

TIPPER, Birmingham.—"Medicated mystery" for horses, cows, calves, sheep, pigs, and poultry; shepherd's black oils, and waterproof blacking.

AMIES, BARFORD, AND CO., Peterborough.—First-prize corn grinding mills, oilcake mills, farmer's steaming apparatus, Camplin's patent steam anchor, portable boiler and steamer, field garden rollers, and model of patent hay and straw elevator.

BURGESS AND KEY, London.—Mowing machines for one and two horses; combined reaping and mowing machines; and reaping machines for sheaf and swathe delivery.

THE TANNED LEATHER CO., London.—Rolls of leather driving-traps in various widths; hose, laces, oil tester, patent test, and powerful fire pumps, steam gauge, tallow cup, speed indicator.

SALMON, London.—Samples of various artificial manures for root culture, &c.

SIMPSON AND CO., London.—Packets and samples of cattle spice.

MARKALL AND SON, London.—Machine for sawing and boring.

SMITH, Kettering.—Horse hoes, grindstones for reaper and mower, knives, and general purpose grindstones.

NICHOLSON, Newark.—One, two, and three-horse power steam engines, patent haymakers, new horse rake, winnowing machine, corn elevator, cake mills, for hand and power, sack lifters, and new patent corn-drilling machine.

MURRAY AND CO., Banff, N.B.—Corn drill sowing machine, combined double furrow and subsoil plough, improved chain pump, and set of zig-zag harrows.

MILBURN AND CO., London.—Portable corn-drying machine, and samples of desiccated grain food for cattle.

MAIN, London.—Specimens of patent continuous fence, field gates and pillars, ornamental wire hurdles, and rolls of galvanized wire netting.

SAMUELSON AND CO., Britannia Works, Banbury.—Self-raking reaper, combined reapers and grass mowers, one-horse "Eclipse" mower, single and double action turnip-cutters, and lawn mowers.

YARROW AND HEDLEY, London.—Three-and-a-half and five-horse power improved steam-engines.

HOFF, Wellingborough.—Samples of cattle, game, and poultry food in bags and boxes.

MURTON AND TURNER, Kenninghall, Norfolk.—Corn-dressing machine, twelve-row corn and seed drill, and six-hand turnip mending drills.

NORRIS AND CO., London.—Rolls of leather belting and bands, fire-hose, buckets, laces, band-screws, and boxes of Buer's patent packing.

RANSOME AND CO., London.—Weston's patent pulleys and sack hoists, sets of rope-blocks, lifting jacks, leather driving bands, steam gauges, weighing machines, grindstones, corn and flour bins, steaming apparatus, rick ventilator, and samples of sheep-dipping specific.

PRIEST AND WOOLNOUGH, Kingston.—Assortment of Norfolk, Suffolk, Surrey, manure, and general purpose drills; patent lever horse-hoes, and patent barrows.

BENTALL, Maldon.—Assortment of patent chaff-cutters, root-pulpers, slicers, single and double action turnip-cutters, oilcake mills, corn and seed crushers, two-horse gear and thrashing machine, ploughs, sets of two and four harrows, and set of two-horse whippetrees.

BRITANNIA STEAM CULTIVATOR COMPANY, Leeds.—Model of Fiken's light rope steam-ploughing tackle.

SHEN, Aylesbury.—Chaff-cutters for hand, horse, and steam power; oilcake breaker, litter and turnip cutters, and tin shovels.

MATYARD, Whittleford Works, near Cambridge.—Patent portable power engine, for cutting chaff, &c.

HUPBURN AND SONS, Southwark.—Single and double endless bands, wire-sown; leather belting, leather hose and buckets, and india-rubber bands, delivery suction hose, &c.

GRAY, Sheffield.—Steel and steel-faced horse-shoes; knives, sections, and fingers for reaping and mowing machine; ploughshares and coulters, chaff-machine knives, turnip-cutters, and various edge tools for farm and garden use.

LEX, Witleham, Surrey.—Woodbury's straw-frame beehives, Taylor's improved cottage hives, Payne's improved hives, centrifugal honey-extracting machine, and collection of honey in glass boxes.

MORISON, London.—Patent hay presses for country districts.

PERKINS, Hitchin.—Pairs of three, four, and five beam harrows; and poles for reaping and mowing machines, with shaft and starting and stopping motion complete.

TAYLOR AND CO., London-bridge.—Improved chaff-cutting machines; crushing mills, pulpers, and slicers; grindstones; improved winnowing and blowing machine; oilcake breakers, portable boiler for farmers' metallic corn bins, American box churns and turnip cutters.

RAY, MEAD, AND CO., London.—Two-and-a-half, three, and four horse-power steam engines, boiler, and fittings complete; corn bins, galvanized iron wheelbarrow, and grindstone mounted on iron frame.

BOY, Bury St. Edmund's.—Patent double-action haymaker; patent self-cleaning corn screen and stone separators; patent corn-dressing machine and screen combined; barley haweller; patent semi-self-acting horse rake; improved malt, gravel, and lime screens; pair of patent plough wheels and stalks; model of wire maltkiln floor, and small screen for corn merchant's office.

WHITNEY AND CO., London.—Corn crushers and grinding mills; portable French burr mills; domestic flour mills, chaff cutting machines, and flour dressing machines.

HOLGATE AND CO., London.—Leather and indiarubber millbands, hose pipes, and buckets.

HILL AND SMITH, Brierley-hill.—Wrought iron sheep racks, cattle cribs, sheep troughs, wheelbarrows, field and entrance gates and pillars; specimen lengths of continuous cattle and sheep fence; samples of wrought iron hurdles; and samples of galvanized and painted wire netting.

HAYWARD, TYLER, AND CO., London.—Two and eight horse power horizontal steam engine; two-horse power vertical engine; Jordan's combination steam boiler for horse power; patent universal steam pumps; irrigation pump; California farm fire engine and pumps; assortment of pumps for power, domestic, and agricultural service; and water barrows and garden engines.

WORSWOM AND CO., London.—Circular saw table for agricultural purposes only.

REID AND CO., Aberdeen, N.B.—General purpose corn and seed drills, single-wheel fore-carriage steerage; improved

marker, and land measure for corn drills; horse rake, set of medium harrows, and double-action wire-straining pillar.

HEADLEY AND SON, Cambridge.—Assortment of new hydraulic apparatus for watering roads and extinguishing fires; rolls of pipe, portable hand pump, and cattle trough.

COTTIS AND SONS, Epping.—Chaff-cutters for hand and horse power; expanding and market gardeners' horse-hoes; dressing machine; set of zig-zag harrows, and barrows.

SMYTH AND SONS, Peasenhall.—Ten-row "Eclipse" and lever corn drills, and manure drills.

JONES, Gloucester.—Gloucestershire Specific for Sheep; composition for waterproofing; and chemical essence for wounds in animals.

EASTWOOD, Blackburn.—Compound action churns, to hold from one to twelve gallons; and one two-horse engine with governors for churning or chaff-cutting.

MATTHEWS, SON, AND CO, Driffield.—Samples of corn feeding cake.

HANDLEY AND CO., Stepney.—One pair of French mill stones, smut machine, and collection of mill necessities.

GOODAY, Chelmsford.—The patent thatch sewing machine.

DAVEY, Croftthole, Cornwall.—Two patent "Excelsior" turnwrest ploughs.

THE FARMERS' SUPPLY ASSOCIATION (Limited) London.—Samples of lined cakes, cattle foods, artificial manures, and agricultural seeds.

STONES, London.—Rolls of wire winnowing machine work, corn, manure, and other sieves; screens, netting, and sack protectors.

VULCAN IRON WORKS CO., Ipswich.—Newly improved self-acting horse-rakes, cultivators, sheep-feeding racks, and agricultural cart.

BOULTON, Norwich.—Liquid manure carts, water and liquid manure barrows, improved machine for spreading liquid manure, garden engines, portable and domestic pumps, new patent lawn mowing machine, assortment of garden chairs, vases, game and sheep netting, and two models of green-houses.

HART & CO., London.—Weighing machines for agricultural and general purposes.

KEARSLY, Ripon, Yorkshire.—Two-horse grass mower, and one-horse reaper.

FOSTER AND SONS, Witham, Essex.—Chaff-cutter, oilcake breakers, turnip cutters, beam mills, cattle troughs, sack barrow, and heavy bottle jack.

FOLLOWS AND BATE, Manchester.—Assortment of lawn mowers, portable stand for reaper knives, grindstones, Manchester powerful pump, and weighing machines.

WOOLF, Bedford.—Improved general purpose plough.

WAIDE, Leeds.—Barrel churns, to make from $\frac{1}{2}$ to 40 lbs. of butter.

TROWBRIDGE, London.—Agricultural weighing machines scales, and weights; and set of seed measures.

KITMER, Fulstow, Lincolnshire.—Corn dressing and blowing machine, and combined dressing and blowing machine.

HUNT AND PICKERING, Leicester.—Steel roller corn-crushers, grist mills, oilcake breakers, chaff cutters, root pulpers, one-horse gearing, turnip cutters, one and two horse mowers and reapers, models of liquid manure cart and cultivator, pair of 4ft. millstones, roller punches, and model of vessel for the transit of milk.

HODGSON, Louth, Lincolnshire.—Sets of harrows, bundles of digging and manure forks, general purpose plough, and corn hoe and scarifier.

GIBBS, Woodford, Essex.—Models of patent hay and wheat dryer, and specimens of dried hay.

REEVES R. AND J., Bratton Iron Works, Westbury.—Chandler's and economical liquid manure and seed drills, thirteen-coulter seed drill, broadcast manure distributors, improved water carts, and harrow pumps and pipes.

HILL, Westbury.—Specimens of agricultural seeds and roots.

REYNOLDS, London.—Poultry fencing, hurdles, coops, poultry troughs, seed protectors, and galvanized wire netting.

CARSON AND TOONE, Warminster.—Chaff-cutting engines, patent turnip-cutters, oilcake crushers, horse hoe, cheese presses, and two-horse gear.

BAKER, Compton, Berks.—Liquid manure cart, pump with suction hose, improved manure distributor, and water cart on wood wheels.

RICHES AND WATTS, Norwich.—American grist mills, "Eureka" grinding mills, "Star" grinding and crushing mills, manure pumps and distributors, cider mill and wine presser, lever drag rake, sheep rack, horse works, oilcake breaker, American ploughs, Child's aspirator, California separator, chaff-cutters, dressing machine, and seed drill.

HAYES AND SON, Peterborough.—Manchester, Plymouth, and Paris Exhibition first prize one and two-horse carts and waggons.

LE BUTT, Bury St. Edmunds.—"Champion" double-action hay-making machines, patent corn and malt screes, collection of registered hand drills, humane hurdle for lambs, mower knife rest, and the perfect watering-pot.

WARREN, Maldon, Essex.—Chaff cutters for hand and power, oilcake mills, single action turnip cutter, iron and wood beam ploughs, horse rake, and wearing parts for ploughs.

SAWNEY, Beverley.—Prize winnowing machines, sheep racks, grindstones, sack holders and sack trucks, one-horse reaping machine, reaper knife stand, and sack elevator.

JAMES, Cheltenham.—Prize liquid manure distributors, with pumps and suction pipes complete, liquid manure pumps, bone crusher for hand and horse power, and an assortment of gapping drills.

WEDLAKE, Romford, Essex.—Three horse power portable steam engine, one and two horse gear patent haymaker, improved horse rake, chaff cutters, portable corn mills, and circular saw bench.

CAMBRIDGE, Bristol.—Patent and improved rollers, sets of Seamen's and chain harrows, winnowing machine sieves, three-wheel land presser, improved one and two horse gear, and improved horse rake.

BRYAN, CORCORAN, AND CO., Mark-lane, London.—Samples of French burr stones, French runner millstones and bedstones, smut and wheat cleaning machines, mahogany flour cylinder, model of silk flour dressing machine, weighing machine, cradle flour scales, stone staffs and prods, jack stick with spirit level, models of malt kiln, corn measures, chronometer, shovels, brushes, and large collection of miscellaneous articles and utensils required by millers.

HOBBS, Basingstoke.—Improved two-horse gear, chaff cutters, oilcake and bean mills, oat crushers, corn mills, sack elevators, and horse hoes.

BALL AND SON, Kettering.—Royal Agricultural prize waggons and carts, patent "Criterion" prize ploughs, improved leader scarifiers, and sets of iron chain harrows.

ROLLINS, London.—American self side delivery reaper, spring tooth wheel horse rake, American haymakers, thermometer churns, ploughs, corn sheller, sack weighing machines, hay forks, ox yokes, American scythe stones, force and other pumps, garden rakes and hoes, hydraulic rams, and garden and fire engines.

WOOD, London.—One and two-horse improved mower; two-horse combined mower and reaper; new one-horse reaper; and Nova Scotia grindstone for mowers.

HURST, Earle Colne, Essex.—Steam-power clover and trefoil seed drawer; one and two-horse power gear, with intermediate motion; corn and seed dressing machine; oilcake breaker; single-action turnip cutter; disc root pulpers; and turnip seed, clover, and grass drills.

PAGE AND CO., Bedford.—Chaff-cutting machines for hand and horse power; set of horse gear; linseed cake, bean, and oat mills; root pulpers; turnip cutters; and sets of harrows.

BAMLETT, Thirak.—Prize swathe-delivery reaper; one-horse reaper; two-horse grass mower; two-horse combined mower and reaper; and stand to sharpen knife bars.

CLAYTON, SON, AND HOWLETT, London.—Double-chamber drain-pipe, tile, and brick machine; patent brick die, self-delivery brick cutting table; hand-power brick press; concrete moulder; and various models of machines in connection with brickmaking.

THE ST. PANCRAS IRON WORKS, London.—General collection of stable furniture, fittings, and utensils, and sheep and cattle hurdles.

DELL, London.—Wheat cleaner, smut machine, and separator combined; smut machines; French-burr millstones; weighing machines; sacks, and trucks.

PICKSLEY, SIMS, AND CO. (Limited), Leigh, Lancashire.—Assortment of chaff-cutters, for hand, horse, or steam-power; turnip-cutters, strippers and sheers; oilcake, bean,

oat, and other mills; pony and horse gear, one-horse standard reaper, two-horse combined reaper and mower, two-horse standard mower, and new patent standard self-raking reaping machine.

BRADFORD, London.—Various sizes of Bradford's patent churns; improved box-churns; sets of improved butter utensils, pulley blocks, portable weighing machines, "Manchester" fire pump, and improved vertical steam boiler.

RICHMOND AND CHANDLER, Salford.—Variety of chaff-cutters for hand and power; assortment of corn crushers; newly improved one and two-horse gear, and steaming apparatus.

COLEMAN AND MORTON, Chelmsford.—Three prize cultivators; improved water or liquid manure cart with pump and distributor; hand water cart; oilcake cutters for hand or steam power; rotary corn screes; improved one-horse gear, patent horse pitchfork or elevator, and samples of shares for cultivators.

BAKER, Wisbeach.—Winnowing machines.

SMITH AND GRACE, Thrapstone.—Collection of grist mills of various power; bean, oat, and cake mills; and chaff-cutters.

BRAGGINS, Banbury.—Specimens of ornamental entrance and field gates, patent gate lock, and sample board of miscellaneous bolts and screws.

SMITHFIELD CLUB DINNER.

The annual dinner of the Smithfield Club took place on the Monday afternoon, at half-past four, in the large dining-room of the Agricultural Hall, His Grace the Duke of MARIOROUGH presiding. The attendance reached to about 100.

On the conclusion of dinner, the PRESIDENT rose and said the first toast that he had to propose to them was one which in an assembly of English gentlemen needed no comment. He should therefore, without further preface, simply ask them to fill their glasses, and to drink with all the honours the health of the greatest lady patroness of agriculture in this or any other country, her Most Gracious Sovereign the Queen (loud cheers, followed by three times three).

The PRESIDENT then said the next toast which he had to give was one of peculiar interest to that gratifying occasion. He had to propose the health of His Royal Highness the Prince of Wales, the Princess of Wales, and the rest of the Royal Family. They were reminded that Her Royal Highness the Princess had just presented her Royal Consort, and he might say the nation, with another pledge of affection; it was an event therefore which they must take peculiarly to themselves, as well as congratulate the Royal pair upon the happy circumstance (Hear, hear). But he needed no words to recommend to their acceptance the toast of His Royal Highness, because he had endeared himself to the country generally by his urbane and popular manners, and especially as regarded the interests of that Club. He had contributed very largely, and in the most public spirited manner, to the show which had commenced that day (Hear, hear). He asked, then, that they would join him in drinking congratulations to His Royal Highness and his very good health, with that of the Princess and the rest of the Royal family (cheers).

The PRESIDENT: It is now my pleasing duty to propose to you the toast which may be considered the toast of the evening, and I am sure that if ever a wish conveyed in a toast has been gratified, that which I now propose to you—namely, "Success to the Smithfield Club"—has been fully realised on this occasion. Year after year you have drunk "Success to the Smithfield Club," and year after year I think you have had abundant evidence that the wish has been amply fulfilled (Hear, hear). We have seen the Smithfield Club rising from its small beginnings, gradually developing itself, and increasing more and more in usefulness, in prosperity, and in the public estimation, until at last it has become one of the most important, if not the most important of the agricultural associations in the kingdom (cheers). I should scarcely place it in competition by the side of its sister institution, the Royal Agricultural Society of England, because, ante-dating as it does in its origin the origin of that Society, I hold this to be as the senior the more important of the two. Still, it is pleasing to think that there are two societies of this character, both conferring an equal benefit upon the population of this coun-

try; both traversing a road full of usefulness and of scientific improvement; and both adding year by year to the prosperity of the nation at large (cheers). In the Royal Agricultural Society we have an institution which promotes the breeding of animals all over the country, and in the Smithfield Club we have an institution which promotes and fosters their breeding and feeding, and their conversion to those uses which are most valuable to mankind. Well, gentlemen, I think I may say that our wishes have been fully gratified in this respect. The show of stock which we have seen to-day, those which have preceded it, and I have no doubt others which are to follow, all testify to the wisdom of those who originated the society, and furnish an example not only to ourselves, but to foreign nations how great we are in the production of the first necessary of life—namely, food (cheers). But let us not rest contented with the advances which we have hitherto made. There is still an enormous field for Englishmen and English agriculturists to occupy. When you consider the important problem of obtaining a supply of food for the vast population, the ever-increasing population of this country, it is no light thing to say that we have it in our power to occupy, and to fully occupy, that field. I should be the last person to say that you ought by any means whatever to restrict the importation of foreign cattle for the supply of the domestic wants of the people of England, or that you should by any artificial means enhance the price of that food which is the first necessary of life. At the same time I feel that we are embarked in a fair and an honourable field of competition, and when we reflect upon the enormous supplies of foreign food which come into the country, we may, I think, put before ourselves this proposition—that here we have a competitor in the foreigner, and that by means of improved modes of breeding, feeding, and increasing the quality of our stock we may occupy a considerable portion of the ground which has been conceded to him (Hear, hear). One thing which has struck me particularly in reviewing the operations of this society is, that I am satisfied, and I believe that most of the gentlemen who hear me will agree with me, that one of the principal elements in the prosperity of British Agriculture consists in the feeding of cattle (Hear, hear). This being so, it ought to be a matter of the greatest consideration with us how we can make that feeding of cattle more general throughout the country. It cannot, I think, be denied that to a great extent the feeding of cattle, of which we see the results in such exhibitions as that in the adjoining Hall, is carried on by persons of considerable means, who have devoted a large portion of their time and attention to the subject, but that it is confined to a comparatively small class. Now I do hope that in future years the effect of the operations of this society and of any new measures that may be taken to advance the object which we have in view, will be to make the feeding of cattle much more general (Hear, hear). I have in my eye, and I could name farm upon farm where I know the greatest possible benefit would be derived by the farmer, a man of limited means, if he could only be induced to feed four, five, or a half-dozen head of cattle; whereas, generally speaking, upon small farms the farmer confines himself to a small flock of sheep, because they require little or no trouble, whilst the feeding of cattle is comparatively, and in a great degree, neglected. I hope that in future we shall not restrict the operations of this society merely to the encouragement of scientific stock-feeding, which I admit is very beautiful to see, and of which we witness the results under this roof in the most perfect manner; but I should like to see steps taken to enlarge the area of this feeding of stock, and to make the British farmer of small means sensible to the great advantage to himself, to his landlord, and to the country of feeding a small quantum of cattle and sending it to our great markets for consumption by the population of this country (cheers). I will not detain you with any more observations of a practical kind; but echoing the sentiments with which I began, I am sure you will concur with me in drinking that which must be nearest to the hearts and wishes of us all—"Success to the Smithfield Club." [The toast was drunk with enthusiastic applause.]

The Honorary Secretary (Mr. BRANDRETH GIBBS) then read the Judges' award of the cups and champion prizes.

The PRESIDENT then called upon the company as an incumbent duty to drink the health of the winners, and wish them joy in the success they had so honourably gained. With the toast he connected the name of Lord Walsingham, and it was received with loud cheers.

On Lord WALSHINGHAM rising to return thanks the applause was renewed with increased vigour. His lordship said, I really feel overpowered by the kindness with which you have received me. I certainly do appear to have been extremely successful, but I take to myself very little credit for it, and wish the credit to go where it is due, namely, to the able and energetic men who manage my affairs, and have brought my flock to its present condition (Hear, hear). I came up to town this morning, with the knowledge that I had some pretty good sheep in the yard, and when I entered it I found myself awarded the first prize for each of the three pens which I had shown, a silver cup, and that other handsome prize which the society has given for the first time this year to the best animal of its kind (cheers). Regarding the show as a whole, I think the general opinion seems to be that it is a fair average one. There are certainly some very beautiful animals there, and, upon the whole, it is a fine exhibition of stock. In particular, I admire the row of Devons, which looks so fine and beautiful (Hear, hear). Now, gentlemen, in these times, when corn is cheap and meat is dear, it is of the greatest importance to the farming interest that we should have breeds of cattle and sheep that will produce the largest possible amount of mutton and beef with as little bone as possible; and, if we take the animals which we have seen here to-day as a type of the animals which are in every part of the kingdom, or at least in every county in the kingdom, I think we may fairly boast that Great Britain and Ireland possess a very large quantity of the finest stock that it is possible to produce (Hear, hear). I believe that even now, however, there is room for improvement, and that it is possible in the course of years, which I may not live to see, that the stock of this country will still very much improve (Hear, hear). There is one animal in the yard which is very different from those I have alluded to. I mean the animal which is described as a South American beast (a laugh). I think we may take him to be the type of a very different description—the type, in short, of what our stock would be if there had been no such institutions in existence as the Smithfield Club and the Royal Agricultural Society of England to stimulate the farmers of this country to produce such magnificent animals as they do (Hear, hear); and I fancy that it would take a good many more animals such as that to feed the large population of this kingdom (Hear, hear, and laughter). You have all had an opportunity of seeing him, and I hope that I have not formed a too unfavourable opinion of him (Hear, hear). Before resuming my seat, the order of the day being that we should not make long speeches, I may be allowed to propose a toast which I have the greatest pleasure in doing, and that is the health of our noble President, the Duke of Marlborough (loud cheers). I know that my noble friend takes great interest in farming, although he has not been able to exhibit anything at your show to-day; but the noble Duke, who has served his country as a Minister of the Crown so ably and so well, condescends to take an interest in matters which are perhaps not quite of the importance of those with which he has been conversant in that capacity, though of great importance to the general benefit of the community, and therefore I beg to give you the health of his Grace the President (prolonged cheering).

The PRESIDENT: It is with heartfelt sincerity that I thank you, not only for the honour you have been good enough to do me in drinking my health, but for the kindness and indulgence with which you accepted me as your president for this year. I confess myself to be only a new and recent member of the Club. Partly from circumstances which have prevented me from engaging earlier in the pursuit of agriculture, and partly from other causes, I have not been able to take that scientific and continued interest in farming operations and the feeding of cattle which has been the happy privilege of my noble friend Lord Walsingham and many gentlemen present, but I can assure you that it has not produced in me any less regard for or less sense of the deep importance of agriculture to this country. I have a very large stake in agriculture; my attention is constantly fixed upon an extensive farm of my own, and it has been a subject of much regret to me that it has not fallen to my lot on this occasion to be a competitor in your hall. That, however, is attributable to an accident which has occurred, and but for which I had fully intended to have offered a humble contribution to the beautiful show which we have seen to-day (Hear, hear). In expressing my acknowledgment to you it is also due from me to return my thanks to these members of the Council with whom I have been associated, and

from whom I have received the utmost co-operation and assistance. Believe me I shall always look back upon the year of my presidency as one of great honour and distinction. It is a subject of great gratification to me that the society is ending this year of its existence, and is about to enter a new one in a position of no less prosperity and importance than at the beginning of the year, and that in entering on the new year it will do so under the presidency of my noble friend Lord Powis, who is not less interested in agriculture, and who will bring to the conduct of the affairs of the Club an amount of intelligence that will make him acceptable to you, and ensure for the Club an equal if not a greater amount of prosperity than heretofore.

Lord DENMAN proposed the "Health of the president elect, the vice-presidents, and the trustees." He might safely say that the improvement of stock was the main object of every owner of land who had the interest of his tenants at heart; and from what he knew of the president elect, he might venture to predict that no Scotchman would be allowed to carry off the prize for Shropshire Downs another year without a severe struggle (Hear, hear).

Earl POWIS (the president elect), said I have to thank you on the part of the vice-presidents and trustees as well as myself for the honour you have done us. It is a source of great satisfaction to all the officers of this Club to see that the show commends itself year by year to those who visit it, and that it expended itself in importance and influence as soon as it obtained adequate room in this very fine building. I must congratulate you upon the success which has attended its removal eastward, and also upon that very excellent building in which we hold it as being of itself a monument of agricultural enterprise. I trust that, next year, when I have the honour of presiding over the Club I shall have the pleasure of meeting all of you again, and that every one will bring a comrade with him (cheers).

Mr. TORR, in returning thanks for the trustees, observed that all testimony concurred in declaring that the show was an excellent one. As an extensive breeder of Shorthorns himself he felt proud of the fact that they had carried off the two best prizes in the cattle classes (Hear, hear); but turning to the sheep he could hardly imagine the Leicesters and Southdowns coming into competition with each other on fair and equal grounds (Hear, hear). He had no doubt, however, that Lord Walsingham's pen of Downs had rightly won, and that Lord Berners' pen of Leicesters had rightly lost; still, if there were to be champion prizes for sheep he held that the Downs and Leicesters could not be put in competition. With regard to what the president had said on the subject of feeding cattle on small farms, he did not look forward to much being done in that respect for the present, and judging from the results of his own practice, he found that the feeding of sheep yielded a profit when he looked in vain for profit from cattle (Hear, hear).

Mr. J. CLAYDEN gave "The health of the judges," for whom Mr. W. H. KEARY (Bridgenorth), one of the judges of cattle, responded. He would like to take that opportunity of reminding the critics of the press that they should be somewhat tender in finding fault with the awards of the judges; they ought to bear in mind that whilst they saw through a telescope, the merits and defects were brought under the eyes of the judges through a microscope. The judges had the opportunity of looking minutely into every condition and aspect of the animals, whereas those public writers who only saw them in passing up and down the alleys of the show-yard, could only speak from a very cursory view, and so formed an imperfect judgment on the merits of the animals (Hear, hear). On the whole he congratulated the Club upon having a good average show. He would not say that he had not seen larger, and he certainly had seen better animals take the gold medals and higher prizes than those which had been successful that day; but the Club might be congratulated upon having fulfilled its mission of producing a large amount of food at early maturity. If they looked back to the shows of 30 years ago, when they were held in Goswell-street, he thought they would agree with him that the meat now shown upon animals three or three and a-half years old was a sufficient proof that the Club had fulfilled its mission (cheers).

The remaining toasts were the "Stewards" and the "Hon. Secretary," proposed by Mr. C. HOWARD, and responded to by Mr. PAINTER and Mr. BRANDRETH GIBBS; and "The Butchers," which was given by Mr. T. BOOTH. The company then separated.

ANNUAL MEETING OF THE SMITHFIELD CLUB.

The annual meeting of the members of the Smithfield Club took place on the Tuesday in the Agricultural Hall, and was well attended. The Chair was taken by the President, His Grace the Duke of MARLBOROUGH.

The Honorary Secretary, Mr. BRANDRETH GIBBS, after reading the minutes of the preceding meeting, which were confirmed, read the following:

REPORT, 1869.

The Council beg to lay before the General Meeting their Annual Report for the past year. The Council have held three Meetings, all of which have as usual been extremely well attended. In addition to the ordinary routine business of the Club, the following subjects have had their consideration:

The revision of the Prize Sheet for the present Show. The Council, considering that the Smithfield Club ought as the national society to offer sufficient inducement to exhibitors to send the finest specimens of different breeds to its shows, determined to offer, in addition to the regular premiums, a Champion Prize consisting of a Piece of Plate, value £100, for the best beast in the yard. This champion prize has been won by the Right Hon. the Earl of Aylesford, who thus takes for his shorthorned steer the following: The Champion Plate, value £100; the Silver Cup as the best in the classes, £40; the First Prize in its class, £30; and the Gold Medal to the breeder.

A similar Champion Prize, value £50, is offered for the best pen of sheep in the yard, thus bringing all the breeds and crosses into competition.

The winner of this is the Right Hon. Lord Walsingham, who takes as follows:—The Champion Plate, value £50, the Silver Cup for the best Pen of Sheep in the show, £20, the First Prize in the class, £20, and a Silver Medal to the breeder.

The Council, taking into consideration the great merit of many of the single sheep shown in the various divisions of Extra Stock, determined to carry out the same principle as regards a champion prize. A Piece of Plate, value £10, has therefore been offered for the best Single Sheep in the extra stock generally.

This has been won by Mr. Wm. Brown.

Several additions have been made in the Prizes for Devons, Herefords, Shorthorns, and Sussex. New Classes for two-year-old sheep have been added in the Hampshire or Wiltshire, and also in the Oxfordshire divisions. A Third Prize for the Ryland, Cheviot, and Dorset sheep has been given, and two Medals for Extra Stock sheep, Shortwools not Southdowns, viz., one for the best Wether, one for the best Ewe.

The following alteration was made in the rule respecting pigs, viz.:—

"That in place of the disqualification being final when the state of the dentition is not satisfactory, the following rule has been substituted:

"If the dentition shall indicate that the age of any of the pigs has been incorrectly returned in the certificates, the stewards shall call upon the exhibitor to prove to their satisfaction the correctness of his certificate."

In consequence of the large number of exhibitors who have been in the habit of paying the non-members' fees for the privilege of competing for prizes, thus only contributing to the funds of the Club in those years when they had animals to exhibit, the Council determined to raise the non-members' fee to Two Guineas.

The result has been an addition to the funds for the present show of £132 6s., whilst several old exhibitors have now become members of the Club.

In compliance with the Resolution of the General Meeting last year altering the bye-laws, the Judges have this year been appointed by the Judges Selection Committee from the list of nominations sent in by the Members of Council.

This Committee consisted of the President and Stewards of Live Stock.

The Council recommend to the General Meeting the following alteration in the bye-laws, viz., "That instead of a Council Meeting being held in March as required in the bye-laws, such meeting shall be held in February."

By this means matters standing over from the Show can be settled without unnecessary delay, and the Prize Sheet can be

issued at an earlier date. This will be a great convenience to those who are about to prepare animals for exhibition.

Attention having been called to the unsatisfactory state of the fittings of the sheep pens and the pig hurdles, the Council communicated with the Directors of the Agricultural Hall Company, who has caused an entirely new set of pig fittings to be constructed. By a fresh arrangement of the pens the drainage can now be properly regulated, and by a modification in the sheep fittings the large breeds of sheep are now provided with pens of increased size.

It having been found that a cold luncheon on the Tuesday of the Show was not well attended last year, and also that the former practice of having the Anniversary Dinner on the Wednesday was equally unsuccessful, the Council determined that the dinner should take place on Monday after the completion of the Judges' Award. The Council anticipated that large numbers of the members, exhibitors, and others taking interest in the Club would be in the hall on that day, and would therefore be likely to attend. The subject of the dinner will receive the attention of the Council at its next meeting.

The Lords of the Privy Council have again granted the special permission allowing animals exhibited at the Club Show to be removed beyond the metropolitan boundary. A Certificate, signed by one of the Club's Veterinary Inspectors, must be obtained, attesting that the animals to be so removed do not exhibit any indication of infectious or contagious disease.

The Council lay before the Meeting the Annual Audited Balance Sheet of the Club from the 1st December, 1868, to 1st December, 1869. The balances in the hands of the Bankers and the hon. Secretary together amount to £2,692 1s. 4d., and the Stock in the Three per Cent. Consols to £4,384 1s. 1d. In conclusion the Council cordially congratulate the members on the continued prosperity of the Club, and also on its having been honoured by a visit from His Royal Highness the Prince of Wales on Monday morning last.

ABSTRACT OF BALANCE SHEET from December 1st, 1868, to December 1st, 1869.

RECEIPTS.

Balance in hand of Bankers, Dec., 1868	£2,672	18	8
Balance in hand Hon. Secretary ...	14	1	10
Received by Bankers—Dividends...	£2,697	0	8
Ditto Subscriptions	119	6	9
By Hon. Secretary of Agricultural Hall Company, Show, 1868	1,000	0	0
Life Compositions	52	10	0
Subscriptions	830	15	0
Fines for Non-exhibitors, 1868	28	0	0
Payments for Implement Stands, 1869	1,647	9	0
Non-Members Fees Live Stock, 1869	264	12	0
	£2,131	15	3
Prize last year's deficit not cashed..	5	0	0

Balance at Bankers, Dec. 1st, 1869	£2,671	0	5
Balance in hands of Hon. Secretary	21	0	11
	2,692	1	4
	£2,136	15	3

Invested in Three per Cent. Consols Stock....£4,384 1 1

On the motion of the CHAIRMAN, the Report was unanimously adopted.

Mr. TORR said he had great pleasure in nominating the Marquis of Exeter as a fit and proper person to fill the office of President-Elect, in other words, President for 1871. The noble Marquis was very earnest in regard to agricultural matters. Most of them were no doubt old enough to remember that the late Marquis took great interest in everything relating to agriculture, and that besides being a great breeder of cattle and sheep, he was a great breeder of race-horses. The present Marquis was equally fond of agriculture, and he (Mr. Torr) was convinced that he would perform the duties of the office of President with satisfaction to the Club, and with credit to himself (cheers).

The Earl of HARDWICKE: Is racing connected with agriculture? (laughter).

Mr. TORR: Well, the winner of the last Derby and of the Two Thousand Guineas Stakes—Pretender—was bred by a small farmer in the neighbourhood of Doncaster (Hear, hear, and laughter).

Mr. PAINTER having seconded the nomination, it was carried unanimously.

On the motion of Mr. Joseph DRUCE, seconded by Mr. TURNER, the Vice-Presidents were re-elected.

On the motion of Lord WALSHINGHAM, seconded by Lord TREDEGAR, Mr. Barnett, Mr. Joseph Druce, and Mr. Torr were re-elected trustees.

Viscount BRIDPORT, in proposing the re-election of the Honorary Secretary, said he was quite sure they could never get a better, and he had very great pleasure in proposing his re-election (cheers).

The motion was seconded by Mr. CROSSKILL, and adopted unanimously.

The members of the Council retiring by rotation were Mr. John Baldwin, Mr. Richard Hornsby, Mr. E. W. Moore, Mr. C. Sewell Read, M.P., Mr. William Sanday, Mr. H. Thurnall, Mr. J. S. Turner, and Mr. Owen Wallis.

The following house list of new members proposed for election was adopted unanimously:

Mr. J. D. Allen, Pythouse, Tisbury, Salisbury
Mr. Joseph Druce, Eynsham, Oxon
Mr. Thomas Duckham, Baysham Court, Ross, Herefordshire
Mr. Walter Farthing, Stowey Court, Bridgewater
Mr. William Rigden, Hove, Brighton
Mr. Richard Stratton, Burderop, Swindon
Mr. Thomas Twitcheil, Willington, Bedford
Mr. Henry Webb, Streetly Hall, Linton, Cambs.

The business on the agenda paper having terminated with the election of several new members,

Lord WALSHINGHAM proposed a vote of thanks to his Grace the Duke of Marlborough for his kindness in attending the meeting, and his conduct in the chair.

Mr. PAINTER seconded the motion, which was carried by acclamation.

The CHAIRMAN said he felt very grateful for the honour which the Club had done him by electing him president of the Club during this year, and for the confidence which had been reposed in him; and it had afforded him great pleasure to render what humble assistance he could, while at the same time obtaining a greater insight into the working of the business of the Club. He was glad that on the termination of his year of office he was to have so excellent a successor (cheers).

The meeting then separated

THE MANAGEMENT OF THE SMITHFIELD CLUB.

Nothing can be more unsatisfactory, not to say discreditable, than the condition into which the conduct of the Smithfield Club Cattle Show is gradually drifting. On the face of it the Council of the Club would appear to have entered into a contract with the Agricultural Hall Company, on the strength of which agreement that building is for a certain space of time handed over to the control of the Stewards of the Club. But in point of

fact this is not so. It would, indeed, be very difficult now to say where the chief power centres. The Council of the Club has passed certain rules and regulations, which it is the duty of the Stewards and the Honorary Secretary to see properly carried out. Previous to the meeting opening to the public very stringent measures have been enacted as to keeping people out. But people are not kept out. Owners, or their relatives, agents, bailiffs, herdsmen, and others, who have no right to be in the Hall, nevertheless get into the Hall, where they not merely look to the comforts of their own beasts or sheep, but frequently put up the entries of other exhibitors. Of course this is manifestly unfair to those who do not get in; while the very natural question which arises is how so experienced and efficient a director as Mr. Brandreth Gibbs should ever countenance such unwarrantable intrusion? But further, the Press generally is favoured with an invitation to attend on the Monday morning when the show actually opens, the card forwarded implying, or more directly intimating, that no representative of a newspaper will be earlier admitted. But it is not so. For some week or so previous the reporter of one daily Paper has the run of the Hall; or it would look, indeed, as if he did everything but sleep there, the best of something to eat and drink being hospitably provided him. During these preliminary proceedings he exercises his avocation, more especially over the implements which are in the course of arrangement; and in performing this office he sees occasion to speak continually in the highest possible terms of one certain stand or so, the exhibitor of which has, curiously enough, something to do with the Agricultural Hall Company. Of course, again, this is manifestly unfair. If the reporter of any particular Paper is to enjoy a privilege beyond his fellows, surely somebody should see to the way in which he discharges his trust; and when, morning after morning, we find the same firm or two belauded, and all the other implement makers left out in the cold shade, we say unhesitatingly that such a violation of the orders of the Club is a gross injustice to those other exhibitors of agricultural machinery. If it were paid for there could not be a more palpable advertisement than this preliminary notice too frequently assumes.

But further still. Let us say that, being anxious to make the most of the time before us, always remembering that our own Journal is published on Monday afternoon—let us say that under such pressure we applied to Mr. Brandreth Gibbs for leave to walk through the Hall on the Sunday after the animals had been placed ready for the judges on the following morning. The reply, as we imagine, would be that no such request could be possibly granted, that no one but the Stewards and the attendants could be admitted, and so on. But this, unfortunately, is not the fact. According to his own showing the reporter of this said Paper was in the Hall on the Sunday night, to see a sight that “was afforded to a very few pair of eyes.” And then he goes on to say the place was “unusually quiet”—that it was “perfectly ventilated”—that “the improvements were manifest,” and to throw out other such puffs direct, not so much for the Club but for the Company’s shillings. “In the great Hall,” as his graphic pen runs on, “most of the animals littered down for the night were carefully swathed and wrapped; but their points could be very well distinguished;” and he proceeds accordingly to prophesy there and then that the winner of the 100 gu., or, in other words, the best animal in the Show will be—a beast which took a third prize in its class! However well primed, it will thus be seen that at the Hall’s own Correspondent did not take much by his visit; but this, of course, is not the point. If one reporter be passed in, why should not others? It must be understood that

we speak by no means feelingly on this matter; for, as Members of the Club, we can now always ensure a look over the classes while these are before the judges on the Monday, and when we can see a deal more than when the animals are “in their rug-paletots and neat canvas suits.” But beyond this even, is it worth while to turn the Sunday into a private view? would the exhibitors like it? or would not the beasts be all the better by being left alone? Some years since there was a horse show in this very Hall, when by way of currying favour in the “very few pairs of eyes” of certain Frenchmen, valuable horses were pulled out and bucketed about on the Sunday, a select performance that was immediately followed by the proffering of apologies, and the voting of censures.

And is the Smithfield Club to come to this? Is the show to be made a Sunday show for the Agricultural Hall people, and their own reporter? Strict disciplinarian as we know him to be, straightforward and impartial as we believe him to be, we cannot think that Mr. Brandreth Gibbs has had any hand in this business. On the contrary, we believe that unwarrantable liberties and encroachments are being taken by people who have no share in the management of the Smithfield Club Show. The Agricultural Hall is, or should be, in possession of the Stewards of the club, and until the first five shillings be paid not a person should be passed in but under the order of the stewards or of the Club Secretary. Have any of these gentlemen given any particular person the run of the place and his teeth before he had any right to enter? We do not think it. But what we do think and know is that one of the Stewards has found the thing so intolerable, has seen the encroachments so rapidly increasing, that he has brought the matter before the Council, with a determination that, if the abuse be not repressed, he will act no longer.

With ten or twenty, forty or fifty apt journalists at work, every man will be pretty certain to get fair play; with one, most probably ludicrously ignorant of that he is doing, everything will depend upon how he is crammed by this salesman or that showman. Indeed, it is to the showmen and salesmen that all the credit of the Smithfield Club is fast coming. We gather from “our own” daily Paper, towards the close of last week, that the Show had gone off exceedingly well, “a fact highly creditable to those who have laboured in promoting the success.” And who are those? Men like Mr. Painter, Mr. Henry Overman, Mr. Turner, Mr. Beazley, Mr. Brandreth Gibbs, and others who have given their time and labour for days or weeks or months past to so successful an issue? Certainly not; but our gratitude, we hear, is more especially due to “the perfected arrangements and straightforward task” of the secretary of the Agricultural Hall, and to “the experience and untiring services” of the sub-secretary, and to “the chairman of the Hall Company,” and to Mr. This, the butcher, and to Mr. That, the salesman, and so forth. Only last year the thing went a little further, when it was propounded, in the largest type, that one of the Hall directors, who was not a Member of Parliament, should be made a Member for his own county forthwith! Such ludicrous, clumsy puffs as these do not, of course, tell for much, but they are significant. They serve to point pretty clearly to the source from which “our own correspondent” gets his priming and his privileges; while we quite agree with *The Daily Telegraph*, which, in a farewell notice of the show, on Saturday, says: “A vexatious, and not by any means honest or justifiable practice, noticeable more and more each year, has now attained such general prominence, that no doubt the necessity of imposing some effectual check will be recognised by that highly respectable but rather inert body,

the Smithfield Club." This, of course, cuts all sorts of ways, for there may be more than one practice, not by any means honest or justifiable, connected with the conduct of the Smithfield Club; and we heartily join in the hope that "this highly respectable,

but rather inert body"—mark the passing sneer—will see the necessity of imposing some effectual check. It shall certainly not be our fault if, not merely as journalist but as members of the Club, something be not done, as there is a deal more to be said on the subject.

THE METROPOLITAN GREAT CHRISTMAS CATTLE MARKET.

Although the past season is generally admitted to have been a very favourable one for stock rearing, we confess that we were somewhat disappointed in the results as shown at to-day's cattle market. Certainly there were some extremely fine animals exhibited, but the general quality was scarcely equal to the average of years. This is the more surprising as the funds at the command of graziers must be large; as, notwithstanding the losses entailed by the great drought of 1866, the very favourable character of the past season has again placed grazing farms at a great advantage. While the past season has proved disastrous to wheat farmers, graziers have been greatly benefited by its humid character, and have been enabled to dispense largely with the assistance of artificial feeding stuffs. Up to a very late period the pastures afforded a good bite of grass for the cattle, and this is a consideration of very great importance. Possibly this fact has been presumed upon too much, and the cattle may not have received artificial food in sufficient quantity, towards the close, to bring them rapidly to maturity. There were undoubtedly some very prime animals exhibited, especially among the cross-breeds, but the pure-breds—which, however, were limited in number—were not generally in good condition. Most breeds were fairly represented, but, as regards numerical strength, the Short-horns and crosses came first. Some of the finest animals exhibited were of these classes, and their character spoke volumes of the great advance which has been made not only in breeding but in grazing, as a science. The show of Herefords was not extensive, but many of the animals were of great weight, and sold at very full prices. The general character of our markets seems stamped for the future, and a large preponderance of cross-bred animals may, from the large remuneration offering by them, be generally expected. The small number of Devons on sale were of fair character, but scarcely up to previous years, either as to quality or weight. A few North-Devons on the stands, however, compared very favourably with any of that breed that we remember to have seen. Very few pure Welsh animals were on offer, but they were generally in prime condition; while the old Sussex breed was scarcely represented. Now that the system of crossing is carried to an extent altogether unanticipated, it is necessary to cry out against the total annihilation of those good old breeds which formerly bore a high reputation in the Smithfield market, but which now stand in imminent danger. The great difference between the pure and the cross-breeds, as marketable commodities, and the rapidity with which the latter are made ready for market, as compared with the time and expense necessary to bring the former into condition, is the obvious explanation of this state of things, and on this account the danger is more threatening.

The Scotch graziers kept up their reputation at this morning's market. Some wonderfully fine animals came to hand, both pure and cross-breeds, and the North British graziers must be acknowledged to be a-head of the Southern competitors in this particular department. We do not mean to assert that there were no English fat Beasts in the market to compare with the Scotch animals,

but we hold that the latter as a class carried off the palm. The Scotch season commenced late this year and the early arrivals were certainly not such as to create any extraordinary impressions of future supplies, but the quality of the Beasts at this morning's market has quite dissipated these forebodings, and there is reason to believe that Scotland will continue to supply us with excellent Beef throughout the season.

The number of mongrel animals continues to diminish year by year. The "in-and-in" system has proved itself altogether unremunerative, and further attempts in this direction will now in all probability be abandoned.

A marked improvement was noticeable in the quality of the foreign animals, those from Tonning being especially good. The French Beasts also were of good character, but the general quality of the foreign arrivals was sufficient to prove that continental graziers are still far behind English breeders in their art.

From Ireland our receipts were to a fair extent, but there was no feature of importance to notice in regard to the animals themselves.

The following return shows the number of Beasts exhibited, and the prices realized for them on the "great days" during the last 28 years:—

Year.	Beasts shown.	s.	d.	s.	d.
1841	4,500	3	8	5	0
1842	4,541	3	4	4	8
1843	4,510	3	8	4	4
1844	5,713	4	0	4	6
1845	5,326	3	6	4	8
1846	4,570	4	0	5	8
1847	4,282	3	4	4	8
1848	5,942	3	4	4	8
1849	5,765	3	4	4	6
1850	6,341	3	0	8	10
1851	6,103	2	8	4	2
1852	6,271	2	8	4	0
1853	7,087	3	2	4	10
1854	6,181	3	6	5	4
1855	7,000	3	8	4	2
1856	6,748	3	4	5	0
1857	6,856	3	4	4	8
1858	6,424	3	4	5	0
1859	7,560	3	6	5	4
1860	7,860	3	4	5	4
1861	8,840	3	4	5	0
1862	8,480	3	4	5	0
1863	10,370	3	6	5	2
1864	7,130	3	8	5	8
1865	7,530	3	4	5	4
1866	7,840	3	8	5	6
1867	8,110	3	4	5	0
1868	5,320	3	4	5	8

We now proceed to particularize the best portion of this morning's market.

Mr. George Dickson's alley was the centre of great attraction, being well stocked with about 850 Scotch-fed Beasts of prime quality. The principal lots from Aberdeenshire were forwarded by Messrs. Knowles, Wishart,

Wyalie, Reid, Beddie, Mitchell, Frost, Bruce, and Shand. Those from Banffshire were consigned by Messrs. Longmore, Stodart, Milne, and others. Mr. Dickson had also on sale 12 superior animals forwarded by Mr. Scott, of Yokieshill, Mintton. To test the capability of the new cattle truck, one-half of the latter was sent in an improved, and the other half in an ordinary truck, but both lots arrived in extremely good condition.

Messrs. Giblett and Son had also a remarkably fine show of animals, among which were 86 extraordinary animals consigned by Mr. McCombie, M.P., of Tillyford, which reached, on the average, £40 each. Messrs. J. Martin, Wm. Mennie of Huntly, Reid of Greystone, Skinner of Aberdeen, were also well represented at the stand. About 150 very excellent French Beasts were disposed of by Messrs. Giblett.

Messrs. Maydwell and Hoyland had some excellent beasts on offer, the property of Messrs. Reid and Elmalie, of Greystone, Vale of Alford; Messrs. Wallis and Strachan, of Turriff; and of Mr. Bryan, of Uppingham.

Mr. T. Duckworth had a good show of beasts, among which was a fine lot of 85 animals forwarded by Mr. J. Hill, of Coatbetch, near Lutterworth.

Mr. Thomas Dixon, had some very fine beasts from Lincolnshire, Northamptonshire, Norfolk, and Scotland.

Mr. Vorley's stand was occupied by a fine collection of animals, and Mr. Wolton and Mr. Walsh had some choice beasts from various parts of the country.

Large supplies of Sheep came to hand, and their general character was good. At Messrs. Lintott and Son's stand there was a fine show of Southdowns, forwarded from Herts, Surrey, Sussex, and Hants.

Messrs. Walby had some choice Sheep consigned by Mr. Palmer, of Benjo, near Hertford, and by Messrs. Woollett and T. Smith, of Sandridge.

Mr. Dodd exhibited some fine Sheep, the property of Messrs. House, Nash, King, and Aldworth.

There was a good show at Mr. John Weall's pens, received from Herts and Berks.

Mr. J. Collins, Mr. Kingsley, Mr. Guerrier, Mr. Eland, Mr. Corfe, and Mr. C. Burrell had some fine Sheep on sale.

STATE OF THE TRADE.

The inquiry for Beasts was not animated, and the market opened very quietly. Some time must elapse before the animals can be slaughtered for Christmas consumption; and, meantime, London butchers will be under a disadvantage as regards keep. The dead meat trade ruled dull; nevertheless, the attendance of butchers became fairly numerous; so, as sales progressed, salesmen showed more firmness, and prices advanced slightly over those current on Monday last. Very choice Scotch and cross-bred Beasts realize 5s. 10d. per 8lbs.; but we regard this as quite the top figure.

The arrivals of Beasts were distributed as follows: From Lincolnshire, Leicestershire, and Northamptonshire, about 2,200 Shorthorns, &c.; from Norfolk, Suffolk, Essex, and Cambridge, about 1,900 Scots and crosses; from Scotland, 1,820 excellent animals; from other parts of England, 1,820 of various breeds; and from Ireland, about 900 Oxen, Cows, &c.

Notwithstanding the increased number on sale, the Mutton trade was fairly active, and last week's currencies were well supported, though seldom exceeded. Really prime Southdowns and half-breds changed hands at 5s. 10d. per 8lbs.

Calves sold freely at fully late rates; and Pork was steady in price.

Per 8lbs., to sink the offal.

THE YORK SALE OF SHORTHORNS.—Mr. Dodd's second conglomerate sale of Shorthorns was, if anything, less successful than the first, which he attempted in the Sea-Horse Inn-yard last year. Nearly twenty more animals swelled the catalogue than were offered last year, and the proceedings began at half-past 12 in a field close to the York Fat Show Hall; but it was dim twilight and a scattered ring-side, ere the last—a red yearling bull of Major Stapilton's, and bred from Lord Feversham's stock—was knocked down at 16 gu. The first five cows were all sold to butchers for about market value. Some cattle belonging to the late Mr. Dawson, of Weston Hall, of Grand Duchess fame, were brought out in good trim, and were apparently useful animals of capital blood. Two, Savannah and Ada, were bought by Major Stapilton respectively at 56 guineas and 40 guineas, and Beauty (a white) went to Mr. Singleton for 40 guineas. Thorndale Lad (23068), a Herd-Book picture bull of Bates' blood, made 88 guineas (Mr. T. Lambe), and Margais (26835) went to the Earl of Zetland for 35 guineas. Lord Milton (26685), bred by Captain Gunter (of the Wild Eyes tribe) for which it was reported a hundred had been asked privately, made the astounding figure of 29 guineas, and goes into Essex; whilst another roan ten months calf by Fourth Duke of Thorndale was knocked down to Mr. Cattley for 26 guineas. A white yearling of Mr. Baxter's of Bates' blood on sire and dam's side reached 15½ guineas, after being the winner of three premiums. Some of the lots were not sent up for sale, and a dull, damp day made the proceedings if anything more miserable.

SALES OF CATTLE AT THE NORTHERN COUNTIES FAT SHOW CLUB.—The cross ox, from Ardillie, sold for £70; the first-prize three-year-old polled ox, from Morayston, was bought for £52; the first prize two-year-old do. for £76; the second prize do. for £47; one of the prize lot of four crosses was bought for £37; the first prize two-year-old heifer for £40; the Morayston first prize Shorthorn ox for £26 10s.; the first prize polled ox under two years sold for £28, and the second prize for £25; the second prize two-year-old stot sold for £34, and the first prize heifer for £36; the Ardross crosses sold at from £33 to £44; the six-quarter-old crosses from Wester Lovat sold at £25 and £26; Raigmore's Highland two-year-old ox for £36. In sheep, Elhot and Co.'s pen of crosses, which carried the Highland Society's medal, sold for 92s. each; the first prize Cheviot wethers for 67s.; the first prize blackfaced wethers for 71s., and the second prize lot from Corriemoney for 62s.

THE YORK FAT CATTLE SHOW.

The thirteenth annual Meeting of this Society has been held in York on Tuesday, Wednesday, and Thursday, December 7, 8, and 9. The attendance during the day has been very select, being principally the gentry and leading farmers of the county, but in the evening the citizens in great numbers attended; so that the financial affairs of the Institution will be left in a healthy state after receipts and expenses have been balanced.

The entries were as follows: Cattle, 69; sheep, 26; pigs, 64; poultry, 334; pigeons, 147; roots, 89. These numbers are more than an average of previous years. Being held at the same time as the Smithfield Club Show the York exhibition is necessarily shown of some of its attractions in the shape of animals that have been sent to the Metropolitan meeting in preference to the one held in the county. Taking into account this circumstance and the prevalence of disease amongst cattle, which has had a tendency to prevent animals being sent from home in railway trucks for fear of catching infection, we think that Yorkshire has come forward favourably in filling the stalls here with a capital and by no means small selection of animals, well worthy of examination by breeders and feeders. The show at York has always one speciality of considerable interest: it is a court of appeal, in which objections to the ruling at Leeds, during the previous week, can be reviewed and revised occasionally. In this instance this revision has taken place in several classes, with results, perhaps we may be allowed to mention, precisely as we predicted, and in others corroborative of the opinions which we then expressed. These instances we shall meet with as we go through the classes.

The character of the Shorthorn exhibition may be defined as moderate in number, but excellent in merit. The three first classes of Shorthorns, thus brought out 15 animals, out of which the judges distinguished with prizes and commendations 15; a fact that at once demonstrates the character of the competition.

In the aged ox class, the winner was Mr. Wiley's roan Shorthorn, which was beaten at Leeds in the Tenant Farmers' class by the black-butcher beast belonging to Mr. Reid, Aberdeen. Our opinion on this, is it not written? Verily there is not a stain on his Shorthorn skin of the representative of Brandeby by his inglorious tussle with the half-caste. He is now in his proper place at the head of his class. We described his "merits" and his "frailties" last week. The second prize is a wealthy fat ox, worthy of his position, a capital carcass, but wanting in style. For the ox under three years old the competition was very close; and the contest in our opinion must have waxed warm, and there must have been "many minds" as to merit even in three judges, when we have in a class of eight three prize animals, one highly commended, and three high commendations, leaving only one animal "out in the cold!"

The first beast is a "new light," and makes his first appearance on any stage on this occasion. We guess, however, that it is not "for once only," as he is likely to uphold the honour of his house for some time to come. He is the property of Mr. G. Taylor, of Bridlington, and is 2 years and 7 months old. He is an upstanding, gray-looking fellow, in fact an exquisite, of the Shorthorn family. His colour is rich, and his hair and handling soft as far, yet firm as India-rubber, smooth as mole-skin, yet rough to the eye—breeders know it when they meet with it. It is here, however, and, in combination with the other points of rare merit—his wonderful crops and shoulders, and first-rate figure generally—have secured to him the first prize in his class, and the President's Cup, value £25 for the best ox in the Shorthorn classes. With so many merits we may venture to name his weak place—his breast-point, and between his hips and tail, both being deficient. We think, also, more weight may possibly bring him down in the middle. The second prize is the property of Lord Zetland. He is 2 years 11 months old, a good red, and the truest-made carcass of beef in the whole show. His hips are not covered merely, but lost, and his form that of a mighty beer-barrel without any protuberances. He is very heavy, and his quality is good; he is deep-

chested, and stands wide, in fact, he is just the notion of "two single gentlemen rolled into one"—if George Coleman's idea were to be realized. Many, very many, place him first; he is, however, deficient in style, has a coarse head, and his quarters from hip to tail are rather short; anyhow he looks queer about his tail, and wants an inch adding there, and also across his hips. We think, however, he is put in his proper place. The next prize animal, belonging to Mr. T. Knowles, Aberdeen, has really not a shadow of a claim to his present position—the third animal—an ox belonging to Mr. Drysdale, who obtained h. c. at Leeds, whom we described as a "true made animal, and fully entitled to the honour." The Earl of Zetland only just beats him. How Mr. Knowles has slipped in third we cannot imagine; but *bonus Homerus dormitat!* The three commended animals belong to Mr. Knowles, Mr. Wood (Thrapston), and Col. Markham (Aberford). The last we described last week; and the two others are good average animals. Altogether the class is one such as is rarely seen, and the judges must have had considerable difficulty in fixing the relative places of first-class animals of such dissimilar styles.

The cow class contained only four, and these four the same quartette we noticed so fully at Leeds. Lord Faversham's Mayflower is here placed first, Mr. Willis's celebrated Rose of Lucknow second, Sir W. C. Trevelyan's red cow 4 years and 6 months old third. This trio of rare merit we fully described in our Leeds report, and we must therefore refer our readers to that for any information as to the personal attractions of all the three, simply saying they are all beauties.

"How happy could we be with either,
Were t'other dear charmer away."

was the position and the feeling of the examiners on this occasion. The decision, however, was given as above; confirming the Leeds position of Mayflower, and elevating Rose of Lucknow above Sir Walter Trevelyan's cow. Our remarks on the Leeds decision last week were: "The Rose of Lucknow is thus beaten by two new aspirants. In one case the decision is sure to be reversed, in the other it possibly may." The best Shorthorn heifer was Sir W. C. Trevelyan's neat little maiden, 2 years and 3 months old. She is pretty in form, with the best possible quality of flesh and handling. The second animal of Mr. Reid's is 3 years and 8 months old, very fat but patchy, with light hind-quarters, and quite another thing to the winner.

The cross breeds were 10, in two classes. Mr. MacPherson's ox, the winner of the champion cup at Leeds, of course wins here, as best cross-bred ox not exceeding 4 years, and the ten guinea cup for the best cross-bred animal, male or female. Sir W. Trevelyan is placed second to him here, as at Leeds, with the same good level Highland ox with a very slight dash of something else in him. The cross-bred cow or heifer is Mr. Bruce's capital blue-black, full of the best of beef and a very great weigher in a little room. He won the same prize at Leeds.

In the Tenant Farmers' Classes a capital ox the property of Mr. Thornton, of Stapleton, won the first. He has the fine style and character of a Shorthorn, though not quite so fat as his competitor, a red and white ox shown by Mr. W. Kirby Wilberforce, which obtained the second honours. The winner has fine frame, straight top, long quarters, good middle and breast end, but has a light neck, and is not fleshy on his rib. The second ox is good in places, but his back is rather hard, and his rump and outfit of beef very deficient. Mr. William Hill, of Wetherby, took first for Shorthorn heifer or cow in the Tenants' Class, with the cow with which he won the same prize at Leeds. She is a weigher in every part, and finishes an honourable career here, having been a prize-taker both at Leeds and York last year. She wins the cup, also value 10 gu., as best Shorthorn in the Tenants' Classes. Mr. Fisher's second prize cow is a very good animal. The best heifer of any breed, except Shorthorn, is Mr. Lund's, of York; and a clever Highlander, of truer frame and symmetry than we have seen out this year. She is not nearly up to

the mark yet in fatness, and will come again and "take honours" some day.

The Scotch breeds produced very small competition. Mr. Reid, Aberdeen, took first and second ox prizes, and first and second for heifers, walking over without competition in one case, and beating Sir W. Trevelyan's black heifer in the other. The same animals met at Leeds, and the judges did not award a second prize.

For Highland ox, and for Highland cow or heifer, the entries were precisely the same as at Leeds, and the awards also were similar; Mr. Drysdale and Sir Walter being first and second for the ox class, and Mr. Eastwood and Sir Walter first and second for heifers. These animals we described last week.

The district prizes for "tenants residing within twenty miles of York," were two, and a cup, value 12 guineas, given by Sir Walter Trevelyan. This cup and the first prize, for best cow or heifer, Mr. William Hill, Wetherley, secured with the beautiful heifer that won the heifer prize in the Tenant-farmers' Class, at Leeds. This animal has the most beef, of the best quality, and the lightest bone of any animal in the yard, and is much too good for her class. With his four years old cow and this heifer, Mr. Hill scores four first prizes and three silver cups at Leeds and York this season, independent of his premiums for pigs and sheep. Verily he is an old cricketer, and knows where to place his men in the field, when he has a good team in hand.

The sheep are a good display, and more numerous than at Leeds; but the winners are nearly the same animals. We protested against the giving the cup for the best sheep in the yard at Leeds to cross-breds from Fochabers, against the pure-breds of Mr. Jordan, or Mr. Byron, Sleaford. We still say that "unless a cross-bred animal is strikingly superior to a pure-bred one, the award ought to go to the pure-bred." And it has been so here; Mr. Jordan getting the cup for the "best pen of sheep" against the Leeds cross-bred winners from Fochabers. Mr. Jordan took first for wethers; and Mr. Brown, Holme-on-Spalding, the second with sheep yet more of the Leicester than Mr. Jordan's; still, as fat sheep, Mr. Jordan wins cleverly. The Southdown and horned Scotch were only moderate. The cross-breds of Mr. Hunter, of Fochabers, N.B., of course took first and second in their class, though they failed for the cup very properly. Mr. Jordan took "best fat sheep" with a famous animal; Lord Wenlock the second prize; and Mr. Brown showed a "commended" fat wether, to our mind a type of the *breed* of real improved Leicester, of which Mr. Jordan's sheep is an *amplified*, and it may be improved, specimen.

The show of pigs is, as usual here, good in point of numbers and quality. There is a local pig-society here, called the Old Ebor, which acts as a feeder to the Christmas Show. Mr. Duckering took first in the large, the middle, and the small breeds severally; his small-bred sow Little Queen, in our report of the Leeds Show we proclaimed "the queen of beauty in these lists," although she did not then get the cup for the best pig in the yard. At York, however, she is chosen out of sixty-four to be the "best animal in the pig-classes," and has the sheriff's cup awarded to her. Could we "spot" the Derby winner in this way, we might attain the dignity of a prophet. Mr. Duckering has sold his three prize animals, winners of endless numbers of prizes, and of treble firsts here, viz., first large, first middle, and first small breed, and also of the Cup—and three other of his show animals to a butcher at Barnsley. The price is 6½d. per lb. live weight. This show will be a sight worth seeing when the six pigs are hung up.

The young bull prizes (special) produced capital competition, there being 14 entries in the two classes. Mr. W. Linton's young animal, winner in the calf class, and Mr. Woraley's in the yearlings, are most promising animals.

The young boars, small breed, were a good class.

Poultry, pigeons, and rabbits, were a large show. It was simply Birmingham and Leeds over again with the weeds picked out, and a few fresh pens added. The entry, therefore, of 550 in these classes is really a large one.

The Judges were, for cattle, H. Ambler, Watkinson Hall, Halifax; H. Peacock, Mount Vale, York; and B. Fawcett, Osbalwick. For sheep, G. Robson, Shires Bar, Easingwold; and J. Holiday, Barmston, Bridlington. For pigs, J. Knowles, Wetherby; and T. B. Whitwell, Gate Helmsley. For poultry,

R. Teebay, Fulwood, Preston. For roots, W. W. Wilberforce, Stockton Hermitage; G. Hutchinson, Prospect House, York; and F. Dickson, Healington.

EDINBURGH CHRISTMAS CLUB SHOW.

The third exhibition of fat stock of the Edinburgh Christmas Club was opened on Wednesday, Dec. 8, in the Agricultural Hall, Leven-street. Taken throughout, the show was one of great merit.

The cattle classes were of course the great centre of attraction. Of cross oxen exceeding three years of age there was a splendid show, the first premium being awarded to a superb brown and white ox exhibited by Mr. McCombie, M.P., Tillyfour. This animal was shortly afterwards sold for £70. Of Shorthorn oxen not exceeding three years, the first prize was given to a fine, compact-looking red ox, shown by Mr. Knowles, Aberdeen. In the polled section, the first place was given to a black ox, the property of Mr. Walker, Altyre, Forres. Of dairy cows there was a large and excellent display, the chief prizes falling to Mr. Hope, Duddingstone, and Mr. Porteous, Merchiston, respectively.

Of sheep, Lord Strathmore's first-prize blackfaced wethers were a very fine lot, one of them especially being as well covered over the back as any Leicester, and otherwise a very symmetrical and well-proportioned animal. Lord Sondes showed a lot of Southdowns, pure-bred wethers, which were commended recently at Birmingham. On handling, several of them seemed very defective in the back, and they compared badly with the wether classes, both of Cheviots and Blackfaced.

Subjoined is a list of the judges:

BULLOCKS.—Messrs. Jonas Wallbank, Berwick; J. McInally, Glasgow; and James Wilson, 146, George-street, Edinburgh.

COWS AND HEIFERS.—Messrs. Christopher Edmondstone, Bradford; Pattison Young, Penrith; and James Harrison, Skipton.

SHEEP.—Messrs. Joseph W. Raddock, Berwick; John McConie, Glasgow; and Andrew Wright, Corstorphine.

Pigs.—Mr. Peter Goose, Leeds.

PRIZES.

Shorthorn oxen, not exceeding three years.—First prize, T. Knowles, Aberdeen; second, W. Drysdale, Kilrie, Kinghorn.

Shorthorn oxen, exceeding three years old.—Prize, P. Fustin, Aberlady, Drem.

Polled Angus, Galloway, or Aberdeen oxen, not exceeding four years old.—First prize, R. Walker, Altyre, Forres; second, R. Bruce, Newton of Struthers, Forres.

Cross oxen, not exceeding three years old.—First prize, W. Drysdale; second, D. Beveridge, Buckthorne, Largo.

Cross oxen, exceeding three years old.—First prize, W. McCombie, M.P., Tillyfour; second, J. and W. Martin, New Market, Aberdeen.

Highland oxen, age considered.—First prize, W. Drysdale second, Earl of Southesk.

Heifers of any breed, exceeding two, but not exceeding three years old.—First prize, Wm. Drysdale, Kilrie; second, H. Sim, Ardullie.

Heifers of any breed, exceeding three years old.—First prize, A. Cowie, Crombly Bank, Ellon; second, H. Knowles, Aberdeen.

Cows of any pure breed.—First prize, A. J. Balfour, Whittingham; second, C. Lyall, Old Montrose.

Cows of any cross breed.—First prize, the Duke of Buccleuch; second, P. Beattie, Dunnydeer, Inach.

Dairy cows, any breed, quality especially to be considered.—First prize, James Hope, Duddingstone; second, A. Porteous, Merchiston.

Messrs. Swan's cup for best animal in the yard.—William McCombie, M.P., Tillyfour.

The Farmer cup for the best animal in the female cattle class.—Wm. Drysdale.

Mr. Bain's silver medal for the best cross-bred cow.—Mr. Hope, Duddington.

Mr. Bain's medal for the best Ayrshire cow.—Mr. Le Lothian Burn.

SHEEP.

(In pens of five).

Cheviot wethers under 23 months old.—First prize,

Bigger, Chapelon, Dalbaccie; second, B. H. Harris, Earahill, Forra.

Cheviot wethers under 23 months old.—First prize, T. Bigger; second, T. Elliot, Hindhope, Jedburgh.

Blackfaced wethers, age considered.—First prize, Lord Strathmore; second, W. Whyte, Spott, Kirriemuir.

Pure bred wethers, other than Cheviot and blackfaced, age considered.—Lord Sondes.

Cross wethers under 23 months old.—First prize, and Messrs. Swan's cup for the best pen of sheep in the yard, D. Shirlif Mairton, Drem; second, J. M'Gill, Dumfries.

PIGS.

Three fat pigs, not exceeding twelve months old, age considered.—First prize, A. Lealie, Asylum, Morningside; second, J. H. Dickson, Saughton Mains.

Three fat pigs, exceeding twelve months, age considered.—First prize, A. Lealie, Morningside; second, J. Wallace, Banbath, Leven.

Fat pig, exceeding eighteen months old, age considered.—First prize, Mr. Gordon, Manar, Inverurie; second, A. Lealie, Morningside.

THE BIRMINGHAM POULTRY SHOW.

After the remarkable displays we have had in previous years, it would be too much, probably, to assert that the present one is superior to all its predecessors; but we may, we think, assert, without fear of contradiction, that it has never been surpassed. The catalogue again opens with the Dorkings, of which there are no fewer than 301 pens—a truly wonderful array as regards either numerical strength or merit. From these figures we are led to infer their increasing popularity as table fowl, while their uniformity of character testifies to the care which their admirers bestow upon the breeding and management of them. The Cochins, though not so numerous as they have sometimes been, may be said to sustain the ground which they have gradually regained. The class of adult buff cocks was praiseworthy; but many of them give tokens of protracted moult. There is a large muster of Brahmas. The adult cocks of the dark variety are very fine; while the class of younger ones amply support the credit of the race and the estimation in which they are now widely held, the hens and pullets being also remarkably fine. We cannot accord the same emphatic eulogy to the light Brahmas, which, compared with the others, look weedy and degenerate. As to the Malays, which stand next in order, they appear to be increasing, there being eighteen entries against eleven last year, and they are also improving. The adult birds are the best. The French breeds muster in strong force, the *Creve-Cœur*s being large and robust, as if they were thoroughly acclimatised in this country. In our opinion they were superior to the *Rodans*, which are irregular in their appearance, and present great diversities of form and plumage, "motley" being apparently "their only wear." *La Fleche*, in which we observe more distinct approaches to a recognised type, was highly commendable. The Spanish was not equal to what have been frequently seen here; but are up to the level of the last few years. The old cocks make a creditable demonstration. The young ones were better; but blackened combs present unmistakable evidence of their having been affected by the late wintry weather. What most strikes an observer in regard to them is that in the males every other quality is sacrificed to the white face, and that the birds have in consequence acquired a dull and ungainly carriage. The pullets are, we think, the best specimens of the race to be met with on the present occasion. The various branches of the Hamburgs are well represented, and several of them are exceptionally good; more especially the Golden Pencilled, which, notwithstanding stained necks in the hens and pullets, are also retrieving their position, so far as colour and smartness of carriage are concerned. The Silver Pencilled are advancing, but not at the same rate. The Silver Spangled cocks are superior to what they were twelve months ago; but we cannot say as much for the hens and pullets. The Golden Spangled and Black varieties make a creditable appearance. The progress of the Polish is more marked, perhaps, than that of any other variety. The blacks, though very limited as to quantity, are admirable in quality; the few pens exhibited being quite equal to any we remember to have ever seen in this hall. The Golden are in a very respectable minority, with no features calling for remark; while the Silver

Spangled kind are advancing in numbers as well as merit. The class for any other variety, as usual, is interesting. The prizes are allotted—the first to a pen of Indian Game, resembling Malays; the second to Silkies; and the third to Andalusians. We must not omit to mention that one pen is occupied by a pair of birds described as "Four-legged Dorkings," but evidently mongrels, the cock in which has an extra pair of fully developed legs and feet underneath the wing on the right side. Besides these there are Frieulands, Padus Chamois, Gangesian Rumpless, Cuckoo Dorkings, Brease, and Hybrid Sonnerata. There is, as heretofore, a very large collection of Game; and all we are called upon to report concerning it is that it is exceedingly fine. The Black-breasted Red variety is strongly represented; but the Brown-breasted Red and Duckwings are also excellent. There is a large muster of Bantams, which diminutive but consequential little creatures are an exhibition in themselves. All varieties of game bantams are shown; black-breasted reds are the most prominent.—*The Midland Counties Herald*.

THE BIRMINGHAM AND MIDLAND COUNTIES CATTLE SHOW.

The annual meeting was held on Thursday, Dec. 2, at the Hen and Chickens Hotel, Birmingham. In the absence of the Earl of Coventry, the retiring president, the chair was occupied by Mr. C. M. CALDECOTT, of Holbrook Grange, Rugby. Viscount Combermere was elected president for the ensuing year. On the motion of Mr. Howard Luccock, seconded by Mr. Lowe, Mr. George Wise, of Woodcote, near Warwick, Mr. J. H. Barbary, Kenilworth, Mr. C. S. Bigge, Much-Wenlock, and Mr. R. H. Masfen, Pendeford, Staffordshire, were elected members of the council, to fill the vacancies caused by the death of Sir George Chetwynd, Bart., of Mr. Samuel Umbers, and Mr. W. J. B. Scott, and the resignation of Mr. Holland, of Dumbleton. Thanks were voted to the past president, Lord Coventry; to donors of special prizes; to the stewards of the various departments; and to Mr. John Shackel, the hon. treasurer. The Chairman said that the services of Mr. Shackel had now extended over so long a period—twenty-three years—and had been of so valuable a character, that he thought the present was a fitting time to testify their appreciation of them by a testimonial, to which he was sure all who were acquainted with Mr. Shackel would feel pleasure in contributing. Mr. Shackel was re-elected honorary treasurer for the ensuing year. The Secretary, Mr. J. B. Lythall, announced that three gentlemen had qualified as life members of the society by the payment of £10 each. There was a general expression of opinion that the money heretofore received from this source should not be expended in current expenses, but either invested in a separate fund, or spent in permanent improvements. Mr. T. B. Wright said there appeared to be an impression abroad that all business to be transacted at the general meeting was previously resolved upon; but he wished it to be distinctly understood that any subscriber was open to, and indeed invited, to make any suggestions he thought proper. A vote of thanks to the chairman brought the proceedings to a close.

DUNSTER CATTLE SHOW.—The following prizes were awarded at the meeting:—£5 for ox, J. Hole, Knowle; £3 for the second, J. Hole; £5 for pair of fat steers not exceeding four years old, G. Risdon, Dunster; £2 for the second, T. H. Risdon, Washford; £3 for fat cow, W. J. Gimblett, St. Decumans; cup for pure-bred bull, T. H. Risdon; cup for bull not exceeding two years old, G. Risdon; £2 for breeding cow in calf, T. Nurcombe, Minehead; £1 for the second, L. Buckingham, Selworth; £3 for breeding cow and her offspring, R. Paramour, Minehead; £1 for the second, J. Burston, Carhampton; £3 for heifer in calf, T. H. Risdon; £2 for heifer, T. H. Risdon; £1 for second, R. Paramore; £3 for pen of five ewes, T. H. Risdon; £3 for two horn rams, T. Nurcombe; £3 for best pen of horn ewes, R. Paramore; £3 for boar, J. Jones, Williton; £1 for breeding sow, T. H. Risdon; £3 for yearling colt, W. H. Langdon, Tivington; £3 for two-year-old draft colt, Mrs. Risdon, Timberscombe; £3 for cart mare, with foal, J. Hole; £3 for half-acre of mangold-wurtzel, T. H. Risdon.

REVIEW.

WHERE ARE WE NOW? A Politico-Agricultural Letter to the Chairman of the Central Chamber of Agriculture (Clare Sewell Read, Esq., M.P.) By W. WALTER GOOD. 34, Bowyer-street, Fleet-street.

In noticing this pamphlet, the *North British Agriculturist* of Wednesday last says "this letter is calculated to damage the Central Chamber of Agriculture, if indeed it does not destroy its future influence as the exponent of politico-agricultural questions." We quote this opinion the more readily as our own estimate of the management of the Central Chamber has long since been expressed; while our only doubt is as to whether we should notice Mr. Good's letter until the answer appears. He writes with remarkable force and point, as well as with an intimate knowledge of all that has occurred behind the scenes. As to the ludicrous incapacity which has from the first marked the direction, Lord Fortescue has already sufficiently demonstrated that very plain fact; but the supporters of the Chambers—and we speak rather of the local than the central element—will learn perhaps with some surprise the uses to which they and theirs have been turned. In such keeping the politics of Agriculture have been made to serve as the cat-paw to certain private ends; people have gone about the country, as in one especial instance, professing to speak to public questions when their real object has been to puff off certain speculations of their own. All this, we repeat, Mr. Good maintains with much power; but we should prefer to see him answered, as answered he must be, if there is any proof in the Chamber, before we go further into the nature of his charges. He addresses himself becomingly enough to Mr. Sewell Read, because, as he says, "I can readily believe that your good nature was appealed to most anxiously and persuasively, when the officials and authorities of the Central Chamber began to merge into a state of desperation in regard to their public influence and pecuniary condition; and I do not doubt for a moment but that you assented—after having declined on previous occasions—to be the chairman for this year, that, under your influence, the then declining Central Chamber might tide over 1869." There can be no doubt whatever that the name of Mr. Sewell Read has done everything for the Central Chamber that could be done; as it is satisfactory to see that he is in no way committed to the other schemes to which this institution has been turned. As our northern contemporary says, "the pamphlet is racy of the soil, and contains many hard hits demanding explanation from the Council of the Central Chamber." In fact, there must be explanations, as we seldom met with a paper which required more serious attention from the agriculturist of this country, or from those to whom the interests of agriculturists have been professedly entrusted. It was the fashion for some time for the creatures of the Central Chamber to say the *Mark Lane Express* was the only journal which ventured to criticise in anything like a tone of censure its peculiar proceedings. We may have, perhaps, been the first to do so; but now *Bell's Weekly Messenger*, the *North British Agriculturist*, the *Farmer*, and Mr. Good, have to be answered; as there can be no possible doubt but that the world will look for this answer.

IMPORTATION OF SHORTHORNS.—An importation of two heifers and two young bulls from Mr. James O. Sheldon's herd at Geneva, New York, United States of America, left New York ex Donan, November 18, 1869, and will probably arrive in this country by the end of the month. The two heifers and one of the bulls have been imported at a very

high price by Mr. E. H. Cheney, of Gaddesby Hall, Leicester. The heifers are Eleventh Duchess of Geneva, red, two year old, by Baron of Oxford (23371), dam Ninth Duchess of Thorndale by Third Duke of Airdrie (23717), and Fourteenth Duchess of Geneva, red yearling, by Tenth Duke of Thorndale, dam Eighth Duchess of Geneva by Third Lord Oxford (23200). The bull is Ninth Duke of Geneva, red with white marks, calved in April, 1869; by Tenth Duke of Thorndale, dam Fourth Duchess of Geneva by Grand Duke of Oxford (16184). The other young bull, imported by Mr. Harvey, Walton-on-the-Hill, Liverpool, on his own and the part of Messrs. Harward and Downing, Kidderminster, is Eighth Duke of Geneva, roan, calved in November, 1868; by Baron of Oxford (23371), dam Third Duchess of Thorndale by Duke of Glo'ster (11839). Mr. Sheldon has since sold half his herd to Messrs. Walcott and Campbell, Oneida County, United States of America. It includes six Duchesses at an average of 1,100 guineas each, and three Oxfords at 560 guineas each. Taking the tribes these prices are certainly without parallel. Messrs. Walcott and Campbell recently exported some of Mr. Booth's animals, including Bride of the Vale for 1,000 gu.—[The "Donau," that brought the Amerian mails and about a quarter of a million of specie into Southampton, also had on board these two heifers and two young bulls. They were safely landed in good order, having had a fair passage of ten days.]—*THORNTON'S Circular for November.*

BATH & WEST OF ENGLAND SOCIETY, AND SOUTHERN COUNTIES ASSOCIATION.

A special meeting of the Council of this Society was held on Tuesday, November 30th, at the White Lion Hotel, Bristol. Sir J. T. B. Duckworth, Bart., in the chair. There were also present:—Messrs. J. D. Allen, H. G. Andrews, E. G. Badcock, J. Townshend Boscawen (Hon. and Rev.), R. Bremridge, C. Bush, R. H. Bush, Thomas Danger, J. T. Davy, R. R. M. Daw, E. S. Drewe, Charles Edwards, Mark Farrant, John Gray, Jonathan Gray, John D. Hancock, J. Hole, H. P. Jones, J. E. Knollys, H. St. John Maule, R. Neville-Greenville, M.P., Thomas Phillpotts (Rev.), W. R. Scott, Ph. D., J. C. Moore Stevens, William Thompson, H. Williams, H. Spackman (Official Superintendent), and J. Goodwin (Secretary and Editor).

TAUNTON MEETING, 1870.—The contracts committee reported that for the privilege of supplying refreshments at this meeting only one tender had been received, viz., that of Mr. William Gibbs, confectioner, Southampton, conjointly with Mr. Hine, wine-merchant and brewer of the same town. As this was the only tender, it was provisionally accepted by the Council, and a discretionary power was granted to the committee to make such arrangements as to minor details as they might think desirable prior to the February meeting of the Council.

GUILDFORD MEETING, 1871.—The Deputation which visited Guildford, on the 4th of November last, reported in highly favourable terms of the site in Shalford Park, proposed to be placed at the disposal of the Society for the meeting to be held in 1871, and it was resolved by the Council that the invitation from the inhabitants of Guildford be accepted, and that the usual conditions be signed by the Secretary, on behalf of the Council, and interchanged with the conditions already signed by the authorities at Guildford.

PRIVILEGES OF MEMBERS.—Several new Members were proposed for election at the next meeting of Council to be held on Tuesday, February 22nd; and it transpired that no person not proposed on or before that day will be eligible to exhibit at the Taunton meeting on the same terms of advantage as those enjoyed by duly elected members. Persons desiring to be admitted as members of the Society should therefore at once put themselves into communication with the Secretary, at his offices in Bath.

THE GRAND PUMP-ROOM HOTEL, BATH.—The Secretary was directed to convey the thanks of the Council to the Directors of this hotel for the accommodation placed at the disposal of the Society, free of cost, for the purpose of holding council meetings there, prior to the removal of these meetings to Bristol.

THE LEEDS FAT CATTLE SHOW.

Despite the circumstance of Birmingham to some extent clashing with this meeting, and taking some of the good animals that belong to Yorkshire—despite the weather being cold and nipping to an extent to make it disagreeable for some to leave their “ain fireside,” and despite, also, the further diminution of the entries of cattle and sheep, by prudential considerations, under the circumstances of this district having been visited with the foot-and-mouth disease—the meeting has been a success in every particular. The show was held in the Smithfield Market Hall, a large rectangular building, 300 feet long by 30 feet wide, in one covered open space. To this a temporary wooden erection of the same size was attached, so as to make a covered show ground of 600 feet by 60 feet wide.

In the first class of Shorthorns, the prize for the best ox of any age fell to Mr. John Orthwaite for his 3 yrs. 11 months old ox without competition. It would have taken a very good animal to have displaced this had there been a large entry, as was proved by the fact that the Innkeepers' Plate of 10 gu. was awarded to him as “the best animal in the Shorthorn classes.” He came very near winning also the Presidents' Cup, as the best animal in the yard, being one of the three best in the ring. There are those who say that this, however, was his due, for he is an extraordinary good even animal, has size, quality, and symmetry; he is, in fact, extremely level in his points, has good hair, colour, and handling, and is a capital specimen of the Shorthorn. He took a second prize here last year, and has “trained on” very well. In class second for best Shorthorn Ox not exceeding 3 yrs. old, there were six competitors, out of which the judges distinguished two—one with H.C. and the other with C.—in addition to the prize animals. The 1st prize ox, belonging to Mr. Pulver, Northampton, is a roan, 2 yrs. and 9 months old, and is well worthy of his position. He has a grand forequarter and capital ribs, his beef is well spread, and he stands straight on his legs. He will certainly be heard of again next year, as he is an animal that will be “going on.” He has a tendency to *embospoint* more than we like, and has a very second-rate purse. In this particular the second animal, the property of Mr. John Orthwaite, has much the best of it; and like the winner of the previous prize, he does credit to Baines. He is a nice roan, and has all the look of a real Shorthorn; his touch is good, and his outline correct; his hind legs are not quite straight enough, and his neck vein and forequarter not equal to the first-prize animal. The H.C. ox, the property of Mr. Drydale, Fifeshire, is fully entitled to the honour. He is a true-made animal, and beef all over; though his meat is not exactly up to the mark in quality, the rough parts being too much developed, and his bone rather coarse; he also looks a little narrow to follow, and his handling is slightly loose. The commended white ox of Col. Markham is a fine, upstanding one for his years; like lads of a certain age he looks leggy, but if he lets down he will make a good big ox; he has a fine long quarter, but is weak in the middle and light in the thigh, and certainly in this class has achieved all he is entitled to. He gains something by standing in juxta position with the worst animal in the class and in the yard—an ox exhibited by Mr. Robinson, of Wingate Hill, Tadcaster—*sans* size, *sans* beef, *sans* symmetry, *sans* everything desirable in a show animal.

The class of Shorthorn cows having had living calves, is the best in the yard. It is worth a very long walk, in very cold weather, to see the three animals that have “taken honours here.” There were eight entries, and the judges have awarded honorary distinction to seven of them; a fact which justifies our opinion of the high merit of the class. The Earl of Feversham gets first, Sir Walter Trevelyan second, and Mr. Willis *prizéed accessit*. The winner, Sweet May, a roan, 6 years and 7 months old, has had but one calf, and makes her *début* on this occasion. She has the Bates' blood in her, and shows it slightly in her hair. The character of her which used to appertain to the Feversham herd is only very slightly manifested. She is by Photograph, dam Sancebox. Photograph was by Skyrocket, a prize winner at the Royal

Agricultural Society's Show at Leeds, out of Piccolomini by 5th Duke of Oxford. She is a gay-looking animal, and exhibits all the characteristics of the breed, and, as a Holderness breeder said, “is full of Shorthorn points.” Although very fat she moves well, and stands well and square on her legs, covering a great deal of ground. The space marked by her four feet on the ground, if enclosed by a line, would form a broad and perfect rectangle. This is rarely seen. She is, however, rather wanting in her fore shoulder, and slightly deficient behind the arm in the girth place. She has, also, one weak button in the back. Her girth is, however, very good, 8 ft. 10 inches. The second prize cow of Sir Walter Trevelyan makes her first appearance also on this occasion. She has Oxford blood in her, and is a very compact piece of beef at first sight. Her handling is too loose, and she is decidedly deficient on the fore-rib; and our opinion is confirmed by her girth of 8 ft. 4 inches, which we have since obtained. She is altogether short; and in fact, she has no business to be second. *Humanum est errare*—and if one man may often err, *tres* judges may sometimes make a mistake. This is one we think, in placing her before Mr. Willis' Rose of Lucknow. It is quite possible that in rejecting this cow for the first prize, for some certain reasons unknown to us, these reasons may have been urged so forcibly against her in comparison with Lord Feversham's cow, that they have not only operated in displacing her from the first prize, but have also operated in favour of Mr. Drydale, who certainly had not the same pretensions to compete with her that Sweet May possesses. The Rose of Lucknow is thus beat by two new aspirants. In one case the decision is sure to be reversed, and in the other it possibly may; as in our judgment it will. The Rose of Lucknow has been out for some time, and has achieved numerous successes. She was the best cow or heifer at Birmingham in 1868; and the winner of five other prizes in London, Liverpool, and elsewhere; as also of Lord Bolton's Cup for the best Shorthorn in the yard at the Richmondshire Agriculture Show in August last. She is between seven and eight years old, and has been so much in public that the general rumour was that she was over-trained, and getting *passé*. Now, it is extraordinary how a *notion*, once given currency to, floats through a crowd, and is accepted for a time. We bowed to it at first, but frequent examination of the class induced us to come to a different conclusion. It is true amongst Shorthorns as amongst “Formosas,” a fast liver cannot be a “girl of the period” for many seasons; but seven years old is *not* a very great age for a cow that has had a calf, and has had to be fattened for the “boards,” on the occasion of the annual agricultural Christmas parties, at Smithfield and Birmingham. In fact, she is only eight months older than the first-prize cow, Sweet May, who could not possibly have been got up in much less time than the Rose has required. But the question is one of fact rather than argument. We cannot detect any falling off; she is still the fine, blooming, full-blown Rose she ever was, a long, deep, and barrel-shaped Shorthorn; her crops are massive, her ribs arched, and covered behind the arm in the girth place with double the depth of beef that any other Shorthorn in the class has; her back and loins are also evenly covered, and her hind-quarters massive, inside the thigh particularly good. The top of her shoulder is rather bare. This is her one fault in our eye; and in this point Lord Feversham's cow fails also. The Rose of Lucknow is, however, inferior to the winner in her flank, and though she stands well, she has not the superlative merit in this point that Fair May has. To whichever of these two animals the palm may be awarded, the decision must be respected. We have an impression, however, that when the problem is worked over again at York, that the result will be different. A nine years' old cow, the property of Mr. Wainman, Workop, is commended in this class. She is short of hair and leggy, but is long and level, and has a commanding appearance; she is a fair specimen of the old style of Shorthorn. Two other commanded cows belonged to Mr. Dawson, Weston Hall, Otley, and another to Mr. Maynel Ingram, of Temple Newsam.

For the prize for best three years old heifer there was no award. The only animal shown by Mr. Reid, Aberdeen, not having sufficient merit. In "other breeds" there was short competition. In the two classes for cross-bred, or Irish, there were only six entries for four prizes and a cup. The class for oxen had, however, the honour to produce the winner of the President's Cup, for the "best animal in the yard," value 20gs. The same animal, of necessity, took first prize for oxen, and also the "Leed's Tradesmen's Plate," value 10 gs., for "the best beast in the cross-bred classes." The second prize ox, in this class, was Sir W. Trevelyan's. He is a dun Highlander, of first-class merit—long and level—and round as a churn. His beef is capital, and despite a little coarseness, he is a capital representative of a Highlander, with a tinge of Lowland blood in his veins. The winning animal, which comes from Forres, in North Britain, on the other hand has, in our opinion, a good deal more of the English than the Scotch blood in him. He is said to be "out of a cow not quite a Shorthorn by a polled Aberdeen bull." He is a good red, without a single speck of white, and of great length and weight. His outlines are both correct and elegant, and he is wonderfully even all over; a perfect *mole* in smoothness of outline and softness of skin; there are neither hills nor dales on the surface of his frame. He is what anyone must call, at first sight, an elegant fellow, of commanding appearance, and though a great weight and fat, he does not look so. Still he is not at all fed up to perfection of the art, as practised at present; and he will, we think, bear a good deal more training; his girth is exactly 9 feet hand measure.

There are only two animals in the yard that had a shadow of a chance with him for "the Cup," in Mr. Othwaite's four-year-old Shorthorn ox, and a Shorthorn heifer in the Farmers' Class belonging to Mr. William Hill, Wetherby, whose experience in bringing out "stars" renders him at all times a dangerous man in his class, be it what it may. Both these animals found many backers for the great event. The Crossbred Cow prize went to Mr. Bruce for a blue-roan polled cow, full of good beef, but of no particular merit in shape. The second prize was taken by Mr. Reid, with a crossbred horned animal, very uneven in shape and make.

In the class for Polled Scotch Ox, Mr. Reid again met no competitors. In this instance the judges awarded the prize. And similarly in the next class, for Polled Scotch Cow, he again walked over with a black heifer, long as a ship, and pretty full of lean beef, but coarse as a hippopotamus, and flat as a barn door on the ribs.

In Highland Cattle there was more competition, and the animals were altogether of higher character than the polled Scots and the crossbreds, the winner of the Champion Cup excepted. Mr. W. Drysdale's first-prize Highland ox and Sir Walter Trevelyan's second prize are only average specimens. The winner of the first prize Highland Cow or Heifer, the property Mr. Eastwood, Clitheroe, is an animal of another stamp. She is a thick, well-fed, beef-to-the-hock beast, of great size, and weight for a Highlander, with a back like a dining table a full thigh and twist, and is a good fleeced one all over. She girths 7 feet 9 inches; exactly the same as the prize Highland ox. The second-prize animal, exhibited by Sir W. Trevelyan, has a capital back, but with beef rather too loose. We certainly prefer the animal *specialty* commended in this class, the property of Mr. Seed, of Clitheroe. She comes from the same place as the winner, to which she is scarcely inferior, though she has not quite size enough; she has as good loins as the winner, and is even more level across from hip to hip, her twist being wonderful.

In the Tenant Farmers' Class the competition was very close, and the animals were of a high order of merit. The first-prize ox, the property of Mr. Reid, is a heavy-fleshed black Angus of great length and great weight. Better beef could not be. His handling was capital, and his breast point extraordinary. His outline is far from correct, his top rugged, and his general symmetry very deficient. He is thin through the heart, and girths only 8 feet 5 inches. The second-prize ox is a very fine specimen of the Shorthorn, of equal weight with the black one he has also breeding, and unexceptional symmetry. He girths 8 feet 11 inches, and was at the head of his class without doubt; and we do not hesitate to announce to Mr. Wiley, the venerable and venerated nonagenarian "father of Yorkshire farming" and veteran breeder of the north, that though he did not get the prize, public opinion

without hesitation awarded him the honour. The representative of the high school of breeding, and successful manager of the Wetherby herd of Duchesses, must have been grievously annoyed at having to agree to this "placing"! The *dead-meat* view we are afraid preponderated in the triumvirate, who have in this case struck out for *suet versus* blood, figure, and weight. If shape and make have nothing to do with decisions in the fat show-yards, when size and weight are *estis* factory, and if the absence of symmetry is to be no demerit, where killing qualifications are present, it will be quite as convincing and much cheaper to use a pair of butcher's scales, than to appoint judges to determine the relative merits of competitors.

The first cow prize went to Mr. W. Hill, Wetherby, for a capital specimen of Shorthorn beef, aged 4 years and 8 months, bred by Mr. H. S. Thompson, Kirby Hall, York. She took first prize here, and as fat cow at York last year. She girths 8 feet 3 inches. The second prize is just a useful animal.

The heifer class under four years old brought out another of Mr. Hill's Shorthorns, 8 years and 11 months old. This is one of the gems of the yard—a tip-top Shorthorn in touch and points, and a thorough fat beast in weight and quality of beef. She has decidedly the greatest weight of beef, with the least of coarse pieces, and the smallest bone of any animal in the yard. Her fore-legs can be comfortably spanned by the hand. Her girth is 8 feet 9 inches. We are told that she stood in last with McPherson's ox for the President's Cup; but this of course we cannot vouch for. If it be a rumour merely, it is one that is extremely likely to be true. As combining the most merits as a fat beast, she will be very near winning in another court, should they ever meet again. Of course she took the Butcher's Cup, value 10 guineas, for the best Beast in the tenant-farmers' classes, as well as the prize in her own class. Mr. Seed took second honours with a very handsome Highland maiden, 3 years and 9 months. In all the local, and also official reports, this honour is placed to the credit of another exhibitor. The mistake arose from the animal in question appearing to stand opposite the second prize card. This we detected when we inspected the class. A very good blue Irish half-bred was highly commended in this class.

The prize for a cow in milk was given to an animal with every point of a milch cow in great force, and several other fine animals were exhibited.

The show of sheep was very small. The Leicester and Lincoln came against each other, and all that can be said is that Mr. Byron's Lincolns were fully entitled to the first prize in the eyes of Lincolnshire farmers, while Yorkshiremen as a rule preferred Mr. Jordan's Leicesters, placed second. Both were equally good of their kind; as fat animals we think the Lincolns would be coarse. Lord Wenlock's Shropshire Downs took the prize in their class mainly from being the only entry. The cross-bred wethers belonging to Mr. John Hunter, of Dipple, Fochabers, were grand specimens of what a Scotch sheep can come to by judicious crossing; they took also the silver cup for best pen of sheep in the show-ground. On the other champion prize, that against all-comers, following close upon the award of the President's cup to a half-bred Scot, shows an extraordinary aptitude in the Scot, when crossed, to combine the excellence of the breeds. The Scotchman is generally said to do well when he "comes over the Border"; and, in this instance, the "Clans" have made a pretty successful raid on the gold and silver of the prize-list, the MacPhersons, the Reids, and the Hunters having come down with a vengeance on the Saxon show-yard.

The pigs were, as they always are in West Yorkshire, capital class. The entries were also very good, 58 animals being shown in nine classes. The first and second prize large breed fat pigs are both worthy of notice. We think that the winner, Mr. Listers, of Amuley, will not hold his own when he comes against Mr. Duckering's second prize pig. This animal has been a Royal, a West of England, an Essex, and a Norfolk winner. He was also distinguished at Altona in Prussia, and many other places, and he will win again. The cup for best pigs in the yard goes to Mr. Keyworth's "sow of the middle breed," a very good animal; but we think not equal to two or three other animals. The small breed sow, the property of Mr. Duckering, we should proclaim to be Queen of Beauty in these "lists." "Little Queen" is well known to fame, and in this instance beats some choice and

male. Mr. Sagar's second-prize sow has the best head we ever saw; but she is growing the worse for wear.

The poultry is a great success at this show. The Leeds Society has followed the example of Birmingham in encouraging this department; and the public has responded, there being large entries of poultry and of pigeons.

The Game classes were a large show, from 20 to 30 in each class; and the birds generally good. The Dorkings were a good show in numbers, and in quality rarely equalled. The year-old birds, which took the first prize and cup, weighed 10lbs., and were the property of Mr. Maud, Leeds. Mr. T. Kell, Wetherby, took prize for Dorking chickens weighing upwards of 8lbs. each! Brahma Pootras were a very fine class; the Fowls also were a capital lot; and the Hamburgs, in all classes, were an extraordinary show, and equal to anything ever seen.

Bantams in every class, but especially black, were numerous

and good. Ducks, geese, and turkeys were also well represented. The price at which owners value their birds is most probably put in to discourage applications to purchase; otherwise £50 for a black bantam and £100 for a couple of geese are fabulous figures to attach to even fancy birds.

In a very good show of roots some splendid swede turnips, grown by Mr. William Ripley, of Kirk Hammerton, won the first prize; they weighed from 14 to 18lbs. each. The man-golds were also very large and handsome.

The financial results of the meeting have been very satisfactory, the receipts being 50 per cent. over last year. There was a strong attendance on each day from the country, and in the evening the town population attended in crowds.

JUDGES.—Cattle and Sheep: J. Ruddock, Berwick-on-Tweed; J. Knowles, Wetherby; H. Spurr, Sheffield. Pigs: G. Hutchinson, York; S. Barret, Harewood. Poultry: E. Hewitt, Birmingham; R. Teesbay, Preston.

THE CENTRAL FARMERS' CLUB.

A FARM AGREEMENT.

The concluding meeting of the Farmers' Club for discussion during the year was held on Monday, December 6, in the Club Rooms, Salisbury Square, and was numerously attended. The Chair was taken by Mr. R. J. NEWTON, President for the year. Mr. R. H. Masfen, of Pendeford, Wolverhampton, introduced the subject on the card—viz., "The Common Form of Farm Agreement as Tending to the Fullest Development of Agriculture."

The CHAIRMAN said, important as the subjects discussed during the present year in that Club had been, he could not but think that the topic on the card for that evening was at any rate as important as any of them, and to his mind it seemed even more important (Hear, hear). It was certainly a subject that deeply concerned the whole agricultural body of Great Britain, while indirectly it concerned the entire community. The title of the subject suggested the important question, Do the present forms of agreement answer the purpose expected—namely, the full development of agriculture? He would at once frankly say that in his opinion they did not. In these days farmers were urged on all hands to use their utmost efforts to improve the culture of the land through the application of steam power, the extensive use of artificial foods for the feeding of cattle, and of artificial manures for the growth of roots, and of course all that meant the employment of an increased amount of capital. Again, the question arose whether under present circumstances there ought to be any restriction as regarded the mode of cropping. In his opinion there should not. He thought that, with the farming of the present day—he was not speaking of 30 years ago—every restriction as to the course of cropping ought to be removed. If a man kept his farm in good condition, so that the land was sure to grow a fair crop, that was, he thought, all that could justly be required. He had remarked that the subject on the card involved the introduction of a larger amount of capital. That suggested another question, Do the present forms of farm agreements allow farmers a fair return or equivalent for the capital which they have invested when their occupations are vacated through death or other causes over which they have no control? Again, he answered in the negative. It would be out of place for him to suggest anything which might have a tendency to remedy those defects, so that might be anticipating the remarks of the introducer of the subject, and he would now at once call upon Mr. Masfen to proceed, only adding that the subject was one which

required to be ventilated, and that, in his opinion, the more it was ventilated, the better it would be for the farmers of England and the community generally.

Mr. MASFEN then read the following paper:—The subject we are assembled to discuss this evening—"The common Form of Farm Agreements, as tending to the fullest Development of Agriculture"—is one of importance not only to the owners and occupiers of the land, but to the consuming population of this great and increasing country. I trust I shall not disappoint the Committee, who requested me, through their Secretary, to introduce this discussion, by reading to your Club this short paper. In dealing with it, I shall have occasion to refer to opinions expressed by different gentlemen and agricultural bodies, who are more able to give a practical solution of this matter than anything I can do; and I will here express the obligation I am under for any ideas or expressions I may have received either from them or their writings. The first consideration must, as a matter of paramount right, be given to the owner of the soil, and in such a manner as is least likely to prejudice the interest of the occupier, extending to the one security for the investment of his capital, and to the other an assurance that the property shall not be depreciated by any incongruous act of an unscrupulous individual who, by misfortune or otherwise, might be disposed to act in a manner at variance with the recognised systems or principles of good husbandry. In introducing this subject to your notice, you are well aware that it is not its novelty that caused the Committee to select it for the concluding evening of this year's gathering, neither can I plead ignorance to some of the most striking features which, at this time, seem to be occupying the attention of the agricultural community; for during the last few years it is a rare circumstance to take up a paper where you do not find that various agricultural bodies have been discussing the very subject we are met together to propound this evening. The mere relation of landlord and tenant creates an implied obligation on the part of the tenant to use a farm in a husbandlike manner, according to the customs of the country where the premises are situated, unless the lease or agreement contains some express covenant or promise inconsistent with such customs and sufficient to exclude them. It is extremely difficult accurately to state the various customs prevailing in different counties, and it is still more difficult in practice to determine to what extent those customs are, or are

not, inconsistent with the special stipulations in agricultural leases or agreements. All disputes should be submitted to arbitration and settled in the usual manner—the customs give way and the express contract prevails. The agreement should be both agriculturally as well as legally good: litigations on agreements and customs can be best controlled by mutual arbitrations between landlords and off-going and in-coming tenants and by the non-adoption of numerous stringent and complicated farming clauses, which are now too frequently introduced, but are of little or no practical value. I often hear expressed that a good understanding between landlord and tenant is an antidote for all ills that may arise between them. No one more highly values the advantage of that good understanding; but that is not all that is required. In how many cases is a considerate landlord succeeded by a spendthrift son, or his trustees? or what guarantee have you that the property on which you are placed may not for a hundred reasons change owners? It would not be necessary for me to give illustrations of the great hardships brought unintentionally upon old tenants by their landlords, in ways the least apprehended by either party, or by circumstances over which they had no control. In the compiling of agreements one fundamental principle must alone be recognized—the owner, the occupier, and the labourer each receiving the consideration due to their respective positions. The owner of the soil is entitled to paramount consideration, which should not be entertained to the injury or disparagement of the others, for be it remembered that an amount of obligation is also felt by the farmer in a degree, which the circumstances of the case demand. The laws of property extend protection to the one, which the other does not enjoy: hence we are naturally led to ask. What is the corresponding amount of capital which a tenant, who is subjected to a six months' notice to quit, has embarked in the occupation, as compared to the relative value of the fee simple of the land? Statistics are not palatable to those who listen to papers of this kind, and tend frequently to embarrass the introducer of a subject, let his information have been derived from the most reliable source. Mr. Mechi's statement of the amount of capital required to farm well and profitably, goes far into the subject before us. As an illustration of the position necessarily existing for better security, if £15 per acre is required, it is one-third the value of the fee simple of the average land of England. The owner, the occupier, and labourer are so identified, that any assistance given to the one is appreciated by the other, as tending most directly to the interests of all. The service of the labourer is so indispensable, that it forms one of the most important elements of success. Without his help, you find the motive power completely scotched, therefore he is not the least worthy of consideration in the subject before us. Each one is a necessary element in the success of the other, the one cannot look for prosperity when the other is not regarded. It is not my wish or intention to stretch out such an array of illustrations as will tend to disparage the one, or claim for the other that consideration which is not due to them. Residing as I do in the mid-land counties, and in a county where I think the great landed proprietors have done, and are doing much in assisting their tenants to develop the resources of the soil to a greater extent than formerly, it must not be inferred that my voice of complaint is raised against *them*, but from a feeling, ay! a knowledge that in many parts of this kingdom there is not that amount either of help or consideration extended to the tenant farmer, either by the landlord or his agent, that is required for a fuller development of the soil. I hope in the paper I have before me I shall not be considered diverging too much from the title it bears, by introducing in various parts matter referring to the social bearing that the three classes, landlord, tenant, and labourer have upon the important question, and how desirable it is that each should progress in accordance with the spirit of the age. This leads me to consider the necessity for a better and more liberal education of the sons of farmers; I view it as one of the most important elements of success. The machinery of the present day is so costly, so are the various scientific discoveries and appliances which have been brought to light, that it renders a liberal education indispensable; and that education it is most essential should be brought within their reach, at a moderate rate. The mere elementary education which has satisfied too many of our class, is to be regretted. What is necessary for the improvement of agriculture is, to attract capital to the cultivation of the soil, by placing in the hands

of every tenant a *good and liberal agreement*. Let the term of tenure be either long or short, afford to the occupier a fair opportunity of a return for the investment of his capital, and at the expiration of his tenancy a fair remuneration for unexhausted improvements. There are many counties where such arrangements are now made, and you need not inquire in passing through any county or district the sort of understanding that there exists. What I and all who think and act with me are desirous of seeing is, "the exception become the rule, and the rule the exception;" let the production of this country be 50 per cent. over its present return. There is a growing feeling in favour of an extension of the principle I so much desire to see carried into general practice. It is not to be supposed the same agreement will suit all soils, or be compatible with the views of all, but, as I before said, all should admit the principle. During the years I have been engaged in the profession of agriculture, circumstances have arisen which never entered the heads of our forefathers, hence so much dissatisfaction is expressed to the agreements, which have not been revised during the last 20 or 30 years, when some of the covenants there introduced, and still retained, are contrary to existing views, and unsuited to the enlightened age in which we live. "Red tape" had too much to do with farm covenants, and in too many cases I fear continues to hold its sway. By this I mean, that when you ask an agent to allow a certain clause or clauses to be removed before signing it, in reply you are told, "Oh! it is of no consequence, you need not take any notice of it, or make exception to it; we don't intend to take it literally, you will not be expected to farm up to those stipulations." Then, I ask: Why allow them to appear? Why not at once remove them? If they are useless dispense with them; if they are of moment insist upon their remaining, and see that your agents insist upon their due fulfilment. "Red tape" placed them there, and in times when the requirements of the land were not so well understood as in the present day. Some few years ago I was one of the individuals who had to award a premium to the best form of agricultural agreement, and I entered the arena of competition, and the thing which struck me most was, *not* the amount of good ones set forth, but the number that appeared in form at the present time. If one-half of their stipulations were entered into, it would place the occupier in a position the landlord never contemplated, and would be attended with no advantage to the estate. It is no wish of mine to insert a ruthless hand, but I contend that it is desirable for all classes that useless clauses should no longer be introduced in farm covenants, which irritate the occupier and find food for that portion of the press from whom we have no favour, but are used as fair weapons with which they make us a reproach to the various classes whose attention they may attract. When we compare the quantity of food and other raw products obtained from a given surface of a well-cultivated country with those obtained from the same extent of an equally fertile country occupied by hunters and shepherds, the powers of agricultural industry in increasing useful productions appear so extraordinary that we cease to feel surprise at the preference which has been so early and generally given to agriculture over manufacture and commerce. Men's attention was first called to the occupation of husbandry, and although we live in a country where the mineral resources have so far placed us in a prominent and enviable position in the scale of nations, our profession must always be "the true barometer of national prosperity": commerce and manufactures pass away; the land alone continues to the end of time. Agriculture, in which I am deeply interested and a zealous and ardent supporter, is the most ancient and not the least honourable occupation in which man is engaged, and I trust I may never be found backward in giving any and all the assistance in my power to remove *some* of the trammels which tend to impede its necessary progress. The agriculture of this kingdom has been labouring under a transition state during the last 20 years, as we know by that period's experience; great changes have been brought upon us, over which the laws of nature had like ourselves no control. Political economy has brought us to a widely different state of things to that preceding the Repeal of the Corn Laws and Sir Robert Peel's Bill permitting the importation of foreign live stock. The principal or staple commodity with many farmers was *wheat*; but from the reduction in its value, caused by the great importations of foreign grain, his attention is naturally turned to another source of profit, viz.: the

production of a greater amount of animal food and wool. The altered circumstances of the case, and the necessity for the employment of a large amount of capital in the occupation of land, render many of the agreements that are now, and have been in force, a clog and a hindrance to that full development of the power of production from our own native soil which the ever increasing population of this country demands. The additional number of live stock, and the enormous amount of artificial food and manures now used, the steam engine and improved machinery being necessary for the production of the same, render that investment imperative. The great obstacle to the improvement of the general agriculture of the country being, as I before stated, the absence of capital, is I fear too frequently encouraged by the number of applicants for farms, and the unwillingness on the part of the agent to inquire more fully into the means at the disposal of the various applicants. We are often reproached for not bringing more of the commercial element into agriculture, and with some degree of force it can be said we are to blame; but our position varies materially from the position of commercial men. If a business in one place does not answer his purpose, he can, with little loss of capital, remove somewhere else; but when a farmer invests, he runs a great risk of losing considerably by the change. Hence it is that other arrangements are imperative for the amelioration of our class. The isolated position of the agriculturist must ever be a disadvantage to him. Before the introduction of railways, we had few opportunities for the interchange of opinions; this I view as our misfortune, not our fault. It is now nearly thirty years since the originators of this Club, who were fully alive to the disadvantages under which they were labouring, determined upon the establishment of these gatherings, the success of which is apparent to all. In taking a financial view of the comparative difference in the expense of assembling a number of gentlemen of our class in this room, and an equal number of the citizens of London, at any given place in their own city, to discuss their general interests, I think the position of the one will compare more favourably to the other than the outer world are disposed to extend to us. In the year 1868 the Royal Agricultural Society offered a premium for the best form of agricultural agreement, or an essay upon the same; and the gentleman who took the prize, gave us a form of agreement which met the views of the Council more fully than any other—and I do not think I can proceed better than by laying before you some of the clauses introduced therein. The Royal Agricultural Society, in awarding this prize to Mr. Cadle, recognise by their act the existing necessity for more liberal covenants. When we consider the importance of that Society, and the position held by those gentlemen composing its Council, I think it must be apparent that a great object is gained, from the fact of such an agreement appearing in its Journal. I do not know what competition there was for the prize; neither is it necessary that we should be acquainted with that fact. The recognition of the necessity for an agreement, in accordance with the altered circumstances of the times, and an endeavour to remove the trammels so often introduced, which prevent the utmost development of the soil, and the acknowledgment of the principle that it is necessary to give the same protection to the capital invested in the occupation that is afforded to the owners of our broad acres—this recognition I consider by the representatives of the first agricultural society in the world (when we know that in the constitution of that body over 70 per cent. are either landed proprietors or their representatives), should carry a weight with it, the effect of which must be felt far and wide if they earnestly assist in carrying out their recommendation. I do not know how far my views may be endorsed by the members of this Club, but if the motive power of the Royal Agricultural Society will assist in carrying out the revolution proposed in Mr. Cadle's agreement, I think we have grounds for hope that a point is gained, and we shall soon find a better system than the present unsatisfactory mode of meeting out justice to quitting tenants. Although the successful competitor is a stranger to me, I have had much satisfaction in reviewing his essay, and can distinguish the practical knowledge of the writer. He tells us it is compiled from various sources, and embodies the best part of Lord Lichfield's agreement, which he considers as complete as any he has seen. I have much pleasure in referring to the name of that nobleman, feeling sure there is no one who knows him as well as I

do who will not feel that any improvement introduced by one so desirous to ameliorate the position of the British farmer, should receive that amount of consideration at the hands of the landowners generally which this great question deserves. It will not be necessary for me to go *seriatim* through the various clauses introduced in Mr. Cadle's essay, but merely to refer to some of the principal parts where a difference of opinion may arise, and where anything so completely opposite is proposed to anything now in general use. This agreement sets forth that the straw, hay, &c., all belong to the landlord, and that the hay, straw, fodder and roots of every description be consumed on the farm, except that certain quantities of hay, straw, and roots may be sold, the full value being returned to the farm in the shape of cake or artificial manure. Now, this is a boon not generally given to farmers, and the great waste you frequently see of straw, where a tenant is compelled to consume it all, is such as to render it little better than rotted straw, returning nothing fertilising to the land for succeeding crops. Referring to the sale of hay and straw, returning the value to the land in purchased food and manures. Railways have done much to render this desirable, finding a ready market for the production of the farm, and the facility for returning the elements for greater productiveness. Another clause not generally found is, that a tenant may sow two white straw crops in succession; now this, I think, will be advantageous in many localities, and not injurious to the land; it has been so in my case, having frequently found a great difficulty in the growth of clover, and in each case, when I have adopted the second white straw crop, preceded by a liberal application of manure, the result has been a satisfactory root of red clover. Mr. Cadle proposes compensation for artificial food and manure, and *that* on a liberal scale, and I think it will meet with many supporters; as far as the *food* is concerned I will go with him, but I am not disposed to sanction his views as regards superphosphates—the last year but one for a manufactured manure. The *last* year in my opinion goes far enough. For draining and all permanent improvements in building, fencing, laying down grass land, and planting fences and fruit trees (the sanction of the landlord for all improvements being given) I fully endorse his proposals, and coincide with his general mode of compensation for the various appliances referred to as the productive elements which a tenant, farming highly, must leave for the benefit of his successor. In all agreements, the great object to be kept in view is to place such an one in the hands of all men, as to give them the greatest inducement to farm well up to the expiration of their tenancy. The great failing in covenants is the absence of any inducement to farm well to the end of the term: no policy can be more mistaken. In clause 9, stipulation is made for all land seeded to be paid for, if clean, 5s. to 30s. per acre, at the discretion of valuers, in addition to the clover or grass seeds sown; thus returning to the tenant an equivalent for good cultivation, for which he would receive no direct benefit, but is enjoyed by his successor. In a discussion at the Midland Farmers' Club, Mr. Randall, of Chadbury, alluded to the absence in almost all agreements for stipulation for clean farming. He proposes that, at the expiration at Michaelmas of any year, half the arable land shall be fit to plant with white straw crops; one moiety shall have been fallowed with green crops during the previous summer; the other moiety shall have been wholly under clover or mixed grass seeds, or part in clover, the rest beans and peas; after being manured, none of the clover or grass seeds being allowed to stand for seed. He requires that not more than one-fourth of the arable land should need to be fallowed in the year after the termination of the tenancy, nor require an outlay of more than £2 10s. per acre to clean it; if it required less than that sum the landlord or the in-coming tenant to pay the difference, if more the out-going tenant to pay it. Then follow the compensation clauses: Not less than one-fourth of the clover or mixed grass seeds shall be mown for hay during the last year, for the use of and to be paid for by the in-coming tenant; for the remainder of the land, whereon clover or other grasses have been grazed the whole summer by sheep, the in-coming tenant shall pay after the rate of 40s. per acre, provided such land be clean and that only one crop of corn has been taken since the previous fallow. There are other covenants that relate to the purchase of manures, which are dealt with in the manner proposed by Mr. Cadle. With one exception, Mr.

Randall proposes that one-half the proceeds of the hay, straw, &c., sold be returned to the land. Much diversity of opinion exists on the time of quitting and entry on farms; it is contended in some localities that Michaelmas is a more desirable time for change than Lady-day. It is not general in my locality; but on several occasions I have valued on farms where a change has taken place at Michaelmas, and in those cases I have found it has given satisfaction. In the Michaelmas change one thing is apparent—that the off-going tenant can clear away, and that the in-coming tenant, by paying for the produce, which is then secured, is at liberty to proceed in all matters without hindrance, and carry on the various operations of the farm, which are often very unsatisfactorily performed by an off-goer who leaves at Lady-day. I should here observe that, although I oppose any set rule of cropping, considering it quite unnecessary, I should require the farm to be given up in a certain course, although the valuers would never consider a farm up to the required standard of good husbandry when a preponderance of any one crop or state of cultivation prevailed. A landlord has an agent, whose business is to attend to his estate, who must keep a schedule of the cropping on each field on entry. All men in charge of estates should be thoroughly practical, who could at once discover any tendency on the part of a tenant to reduce the standard of his farm, of which he should remind him; and, in case of a second intimation being found necessary, he should give him notice to quit, and remove him. This would be attended with much more salutary results than requiring him to sign a stringent agreement and farm by it, believing he could do little injury to the property, when each succeeding year might find him and the land in a worse position than the last. As a general rule, it is bad for all classes that he should remain. This, I fear, has had more to do with impeding the progress of British agriculture than many are aware. A great landowner and myself have many times spoken of this subject, and on one point we could not agree; but recently, I am pleased to say, he has entertained my views. I always contended an agreement should be made to suit a good tenant. He said, "No: there is no necessity for one with a good tenant. They are required to make bad ones farm better, and against any fraud that might be practised." My reply was, "Give liberal agreements, and the number of bad tenants will soon be reduced to the lowest possible point. All practical men know much land is improved by the aid of artificial food, and the extent of benefit it derives from a liberal diet to domestic animals. The return for invested capital is not expected to be made by the animals who consume the food, but from the fertilizing properties of the manure: hence, you see, the want of recognition in all farming customs of ancient date. It is now an ordinary thing for men to expend annually sums amounting to half, or in many cases to even more than the rent of the land: it is, therefore, self-evident that, under a six-months' notice to quit, and no saving clause in an agreement to protect a tenant from contingency, it is obvious improvement must in a great measure be retarded. It must not be imagined that the present occupier is the only party interested in these things; the landlord also, and the in-coming tenant, are equally concerned; and, as I said previously, I view it as a great national question, and in no other light can I consider it should be introduced to the community at large. In some instances the manure upon the farm belongs to the tenant; he pays on entry, and, as a matter of course, receives for it on leaving. In that case there is no object gained by lowering the condition of the farm. If he has a limited quantity of manure on entry, and leaving a larger proportion at the expiration of his tenancy, he receives for all additional, and is thus recompensed for the expense to which he has been by that increase. This is considered by many farmers the best form of occupation, and as one of the best of all old agreements has certainly much to recommend it. In other counties there are various customs in general use, called compensation for dressings and acts of husbandry, that find favour as tending to a good state of husbandry; the off-going tenant receives compensation for the last year's artificial manure bill, deducting certain sums for the roots, as per the mode of consuming them. Another most important consideration for the tenant is to see that he stipulates for the provision of good cottage accommodation. We are often told we provide our cattle with comfortable and warm shelter, but the lodgings of our agricultural labourer is not

taken into consideration. This is a thing that requires attention; proper accommodation within a reasonable distance from his labour should be provided. The Union Chargeability Act has in some measure removed an obstacle in the way of this great good, but there is much still to be done to make the matter as satisfactory as I could wish. Lord Leicester expressed a good opinion upon this subject a few years ago. He told us that in improving the dwellings of the labourer we were not to expect a return for our capital direct, but must charge the additional convenience we receive with some share of the expense incurred, which should be borne by both landlord and tenant; and in that view I think he would find many of those best able to express an opinion join him. The labourer must be better educated, and with that increased education you fit him for a more elevated position in the social scale, and in no way so well reward him, as in increasing the happiness of his own freidae. Education enlightens him, and should make him a better labourer, and that same information makes him more alive to the position in which he has been too much of a reproach to our class and of commiseration by another. I believe the agricultural labourer of this kingdom will bear favourable comparison with the operative classes generally, still I consider there is necessity for his condition being improved, the requirements of the age make the service he has to perform more intricate than formerly. The education of the labourers' children will occupy the attention of Parliament during the next session, and I trust that in dealing with it provision will be made to educate them to the position they are expected to fill; and if in addition to their book knowledge some scheme can be devised for their technical education, an additional object will be achieved. The steam engine, plough, reaping machine, in fact every new appliance for the general cultivation of the farm, is rendered more valuable, the amount of property in the shape of machinery more costly than formerly, hence you require a better man, as more intelligence must be brought to bear in nearly every branch of labour in which he is engaged. The next is one of the most difficult questions to deal with in connection with landlord and tenant, I allude to game. Mr. Cadle, in his agreement, provides for the destruction of rabbits all the year, and for no dog during the breeding season, which is quite right, and with the general stipulation I agree. With regard to compensation for damage done by game, I cannot coincide with the proposal, knowing from practical experience the evil attending the clause, viz., "To allow for all damage done by game exceeding 20s. per acre for each and every acre so injured," and the delusion it has been to hundreds of tenants, to suppose they are secured against damage (which apparently they are); but at the same time, in grasping at the shadow, they too often lose the substance. This is apparently a practical solution of the difficulty, but I fear it is only the beginning of greater differences than at first sight appear. I have frequently been called in to assess damages done by game, and all who have been similarly placed will agree with me that it is surrounded by a variety of disagreeable circumstances. You must first as per this agreement submit to an amount of damage, receiving no compensation; you then have to make a claim of a nature not the most agreeable, and no claim is viewed either by a landowner or his advisers with a more jealous eye than the one alluded to. I will ask you as practical men. In how many cases of this kind have you not found that a notice to quit has followed on almost the very next opportunity after such a claim has been made? if, gentlemen, you have not, I have. When consulted upon matters of this kind, my first question is, Do you value your occupation? if so, do not do anything likely to irritate your landlord, or those in his employ, for it must be well known there are besides the owners those who are often fully as difficult to deal with in things of this kind. I believe no greater evil exists than this over preservation of game. I am sorry to see in many localities great tendency to that end, the un-English fashion of "batter shooting" finding favour with too many. I should be sorry indeed to deprive noblemen and gentlemen of the recreation afforded by the sports of the field; every good tenant wishes and is proud to find his landlord a good day's sport, and happy to entertain him and his friends. Another most objectionable practice on some estates is to introduce a second tenant to *setting* the game. This should *never* be done without first offering it to the tenant, and if he refuses to have it at all value placed upon it when he takes the farm (which shows

always be a fair one) the landlord should then be considered at liberty to deal with it as he thinks well. The case of Mr. Dickson, tenant to the Duke of Portland, is familiar to many, and the state of things there disclosed, where game, was set to a company, and the unpleasantness which ensued; and there are hundreds of cases which I fear are much on a par with it. I look for the whole question to be more completely set at rest by public opinion being brought to bear upon it than anything else. Men and things are more influenced by that than by any other power. The law now gives the tenant the game, but by a voluntary act he resigns his right to the owner, feeling at the same time he has little option in the matter. But here I could observe that in all cases where land is set at a reduced rent for the over-preservation of game, it is only just that the rates should be in the same proportion the land would yield if there was not that joint occupation, which arrangements of that kind must be considered. We are now frequently called upon to pay rates for its protection, adding to our rates by the fact of police being interfered with in their useful work, by being called upon to protect some ardent sportsman's game and assist his keepers. Nothing tends more to fill our goals and workhouses; and be it remembered that no class contribute so largely to the rates of this country as the occupiers of the land, and with the imperative necessity that exists for producing a larger amount of food for the increasing population of this country, the public require that every obstacle should be removed that interferes with the largest amount of production for their use. It is not well to attack private interests upon public ground, but if there is one question more than another where that is admissible, it is on the subject we are now considering. Agricultural energy, enterprise, and skill are much retarded by localities where you have an over-preservation of ground game, and, assuredly, the interests of the many should receive a prior consideration to the pleasure or caprice of the few in support of that system which makes less than valueless some thousand acres of the best land in this kingdom, and compels us to seek food for our teeming millions, from sources which could not add so much to our natural prosperity as when it is produced from the sources within our own command. I refer to those instances where there is an excessive preservation. There is one remark I wish to make upon the rabbit clause in Mr. Cadell's agreement; it provides for the destruction of them at any time, but there are hundreds of farms where rabbits never remain on the land during the day, although at night they visit you by hundreds, to the utter destruction of your crop. Now, in cases of this sort, the stipulation affords no remedy, you have no power to enter the coverts where these pests of the farm take shelter during the day, and to attempt to interfere there would be considered sacrilege. I know two instances under my own observation where the tenants have great damage done them, and where the privilege of catching is given as stated in the agreement: they both say they could not kill a couple if they were offered a hundred pounds for them. In one case a small covert adjoins some arable land, and in three years over one thousand head of rabbits have been shot and otherwise killed in the covert, but not one single head outside. Now where, would I ask, were all the one thousand fed? by whose property were they rendered a marketable commodity? There never was a time in the history of this kingdom when the question for discussion this evening presented itself to us with the same force as the present. In feudal times, and when men made laws to protect their own individual interests, as of yore, the will and action of the one was subservient to the other, there was then little fear of the one moving more rapidly than the other thought desirable to proceed; but now the case is widely altered. We are placed in competition with the world, and that competition becomes keener every day. The great resources our continental neighbours are bringing to bear compel us to move at an equal pace. Railways, canals, and all means of locomotion are extending themselves as rapidly there as at home. The amount of our machinery which is exported year by year must tell its own tale; and whether we are disposed to look with enviousness, or bestir ourselves, it is evident to me that the great changes which we have witnessed during the last few years are only the beginning of the great transition to which I before alluded, and render every effort we can make desirable to keep pace with foreign competition. The great resources of Russia are now being developed by the

extension of railways, bringing grain to the ports at a price never before known. America, who is now recovering herself from the calamity occasioned by internal commotion, will be found a greater exporting country than before, the great drain of the over-population of our sister island doing much to develop the best resources of the virgin soil of the Far West. All these, I say, point, with more force than I can express, the necessity there exists for the removal of every unnecessary hindrance to the fuller development of our native productions. When we review the amount of imports of corn, wool, bacon, butter, cheese, eggs, &c., which annually reach our shores, it must be conclusive to every one that we can only keep even in the race, not only by the removal of all obstacles, but by emulation and encouragement. The interest of the landlord (or I would rather say supposed interest) alone being considered an amount of superfluous matter, being introduced and still insisted upon in farm covenants, acts as a certain barrier to a better cultivation of the land. Let two estates contiguous to each other be set on terms to suit the ideas of men entertaining opposite views upon this question, and I will undertake to say that in five years the tenancy and the appearance upon the one will contrast very differently and most favourably with the other. I am unwilling to believe that there are men to be found who would wish to hold their tenants in bondage as it were, but in honesty I am bound to say I have heard a landlord say, "Smock-frock men are the tenants for me." If such a state of things exist, and I believe it is only in isolated cases that they are to be found, this Club will join with me in expressing an opinion that landlords with these views are as much to be pitied as the unfortunate men who become their tenants. The attention of Parliament will be called next session to the land question of Ireland. I do not hold an argument in favour of fixity of tenure, but what I say every agreement should give is this: A fair compensation for unexhausted improvements. Only recently a landlord told his tenants and the general public at an agricultural dinner, that his tenants felt as secure as under a hundred years' lease; and so they may, but he did not tell them of the hundred and one circumstances that might arise to make them consider that the long reposed confidence had been misplaced. How many sales of large estates are going on every year and breaking off old connections! and it must be borne in mind that there is no old association between our millionaires and the tenants of a century upon old territorial possessions; one single discordant sound of the auctioneer's hammer dissevers those ties which preceding generations would have scorned as idle dreams if the slightest insinuation had been made of their possible termination. Has not the uncertainty of life, too, on the part of the occupier told its sad tale to too many widowed mothers and fatherless families? the *all* spent in putting a farm in a good state of cultivation, with the hope of a profitable return for the investment, when the ruthless hand of the destroyer has made desolate that once peaceful, confiding, and happy home. It requires more of the stoic than I command to say that this is a desirable state of things. I am no alarmist, and I hope this Club will not consider I am painting an exaggerated picture. I fear it is in the power of too many who hear me to endorse to the fullest anything I have sketched, in setting forth the various modes in which these questions may be presented to the world in a true and instructive, but not in the most agreeable position for them to be portrayed. When this Club last assembled here it was to listen to one of the most elaborate and instructive papers ever read before it. I have had much pleasure in perusing it, setting forth the comparative difference between continental agriculture and our own. I was prepared to hear we were ahead of them, but we can plainly see, from the information Mr. Howard so kindly conveys, that as rapid strides are being made there as here, and gives the same warning to us, which I thought well to make in a preceding part of my paper. Irrigation and sewage, which he points out as being carried on in Italy and Switzerland, are bringing about great changes in those localities, and are deserving the attention of both owners and occupiers, who should realise the necessity for rendering available all possible matter for the reproduction of fertility to the soil, and make serviceable that which in some districts is injurious to the locality and prejudicial to health. The large and important town of Wolverhampton is at this time preparing to convey their sewage, for the purpose of irrigation, to a farm adjoining my

own occupation, the progress of which undertaking I watch with much interest. Mr. Howard speaks unfavourably of small farms, and the honourable member for East Norfolk, Mr. C. S. Read, confirms the opinions he expressed; and within a few miles of the neighbourhood in which I reside, I have seen enough to convince me of their undesirability—prejudicial alike to the owner, the occupier, and the labourer. Small farms are let at a higher rent than larger ones, and such must of necessity be the case as security against loss, and from the general want of capital upon such occupations much less return is made. To the labourer, no doubt the large farms are of the greatest advantage, giving continuous employ, and on the other only occasional occupation, which I believe to be most dangerous to the labourer, as well as being attended with consequences disastrous to his family. No one with half-employment can be considered a desirable labourer; they are frequently the worst men, and when partially occupied, generally require higher wages than are ordinarily paid—and this has the effect of making them dissatisfied with that fair and equitable compensation which is extended to men in constant employ. Hence it is conclusive that small holdings pay for casual and temporary labour a higher rate of wages than larger ones. One word upon Scotch farming and leases: As you are aware, in Scotland the general system of tenure is by lease of 19 or 21 years, renewable at a certain period, prior to the expiration of the term specified. The system of farming there has much to recommend it to our notice—land well-farmed, masters and labourers happy and prosperous, the amount of capital there invested contrasting very favourably with that of England. No complaint can there be heard of the uncertainty of tenure, and the want of security for invested capital; the tenant immediately makes a liberal investment with an assurance that there is an opportunity during his term to reap the reward of the same—and it is as applicable to the case of a yearly tenancy, if the security which Mr. Cadle sets forth in his essay be acted upon. We were told by the late Mr. Grey, of Dilton, a lease will bring a barren heath to the productiveness of a garden, and that a yearly tenancy will return the garden to its original desert state. This cannot and must not be considered a tenant's question only. I feel persuaded that if either of the systems here proposed were generally adopted, it would tend more than anything else to increase the value of the land of this kingdom, and would give nearly cent. per cent. more available food for the people. And is this, I say, a thing of slight moment, when we consider that in the last three years we have imported into this kingdom grain to the value of £37,000,000, and £5,000,000 annually of live stock, irrespective of the value of butter, cheese, bacon, eggs and wool, all of which find a ready market here? Mr. Allison has recorded an opinion that the husbandry of Flanders in our plains, and of Tuscany on our hill sides, would easily raise food enough for double our population. Mr. Smith, of Deanston, whose name will everywhere command respect, has expressed his conviction that by draining and subsoiling alone, leaving the question of manure out of sight, that Great Britain in 20 years will become a corn-exporting country; while Professor Johnstone, in his lectures upon agricultural chemistry, expresses his deliberate conviction that, as a whole, this island does not produce one-half the food for man which it might be made to bear with profit to the farmer, and which by the time our population is doubled he believes will be found readily to yield. His Royal Highness the late Prince Consort, who took so deep an interest in the progress of agriculture, in one of his speeches said: "Agriculture, which was once the main pursuit of this as of every other nation, holds even now, notwithstanding the development of commerce and manufactures, a fundamental position in the realm; and, although time has changed the position which the owner of the land with his feudal dependants held in the empire, the country gentleman with his wife and children, the country clergyman, the tenant and the labourer, still form a great and, I hope, united family, in which we gladly recognize the foundation of our social state. Science and mechanical improvement have in these days changed the mere practice of cultivating the soil into an industrial pursuit, requiring capital, machinery, industry, skill, and perseverance in the struggle of competition. This is another great change, but we must consider it a great progress, as it demands higher efforts and a higher intelligence." His Grace the Duke of Marlborough so

aptly said: "Whatever the material prosperity of the country may be, it must be based on that which supplies the resources of natural life and vigour to the nation." Sir John Pakington also "repudiates the idea of a man placing confidence in his landlord; let him treat it commercially, and place his trust in a written document." If then we are to credit these assertions—and I fully believe to a great extent in their correctness—I ask my brother farmers if we should not be "Up and doing." The name of Earl Ducie is familiar to most in this room; his views upon the question before us are clear and concise. At an agricultural dinner he thus addressed those present: "Those farmers who look with dislike upon the progress of improvement, under the impression that it operates against themselves, could not entertain a greater mistake, for go through the length and breadth of England it would be seen that where the landlord was found the most enlightened, the tenant was found in the most flourishing circumstances; the tenant knew his duty to his landlord, and the landlord to his tenant. No question could affect more the relative position of both parties than that of leases, and his opinion was, that till that question was fairly and clearly understood, all their efforts after improvement would fall short of what they ought to be. He (Lord Ducie) would give every tenant a lease, but in return he must have intelligence. He considered a man a fool who invested his capital without security." Mr. Randall says, that by sensible and business men, a lease was considered most desirable, but we are often told by landlords what we know to be a fact, that in very extensive and highly cultivated parts of the country (he alluded to Yorkshire and Lincolnshire) land was occupied from year to year. The farms in the neighbourhood alluded to remained from generation to generation in the hands of the same family of tenants, who considered if they had leases their farms would be re-valued, and might be called upon to pay an increase of rent, which increased value was mainly due to their own industry and outlay. I need not in concluding this paper, detain you more than a few minutes in taking a summary review of the points which I think of the most importance for the better security of invested capital, and for the mutual progress and advantage of all classes. In the first place I feel bound to express my opinion in favour of a lease, considering it the best security for investment of capital tending to the independence of the occupier, and an increase of value to the landlord, with a largely increased production for the benefit of the nation at large. Secondly, in cases where an objection is made to granting a lease a liberal tenant-right should be given, extending a scale of compensation for unexhausted improvements, and for clean farming to such an extent, or in an equal ratio to that proposed in the agreement selected by the Royal Agricultural Society, and with at twelve months' notice to quit. Having referred to some of the first men of the age, and adduced the opinions expressed by them and of those now removed from us, whose memories are still dear, and considering the views they entertained and expressed bearing upon this subject, and to which I will here again call your attention, his Royal Highness, the late Prince Consort, aptly alluded to the position we occupy in the social scale. I have referred to Lord Lichfield from the interest he has always taken in the welfare of the British farmer; to his Grace the Duke of Marlborough, to show how much the prosperity and vigour of the nation depends upon the supplies of the resources of natural life; to Earl Ducie, the late Mr. Grey, of Dilton, and Mr. Randall, on the advantages of leases; to Mr. C. S. Read, M.P., and Mr. J. Howard, M.P., on the comparative advantages to the public of large over small farms; to the late Mr. Smith, of Deanston, on the value of drainage and subsoiling; to Professor Johnstone and Mr. Allison, on the practicability of largely-increasing the production of our broad acres; to Lord Leicester, on improving the dwellings of the labourer; to Sir John Pakington, for the necessity of treating contracts between landlord and tenant commercially; to Mr. Mechi, as tending to show that a much larger amount of capital is required for the improved cultivation of the land; to Mr. Howard, in drawing our attention to the importance of irrigation and sewage; to Mr. Cadle and Mr. Randall, as showing the necessity existing for an equitable tenant right in the absence of a lease; and to the Council of the Royal Agricultural Society, by offering a prize for an essay on farm customs recognizing the necessity for a better understanding between landlord and tenant. Perhaps

I may have disappointed some present by not recommending something more definite on the vexed question of game; but from the experience gained by our brethren in the north, you will, I think, see that those who are agreed on things generally have found greater differences arise in this matter than they were disposed to admit. Having referred fully to this question, and introduced instances of the disastrous effects arising from over-preservation, will, I have no doubt, tend to a discussion and expression of opinion, from which I trust more practical knowledge tending to the solution of the difficulties with which this question is beset, than anything I can adduce; and before I resume my seat, I would say that the landlord should feel that his property is in the custody of one who will not depreciate it, the tenant that his capital is invested in that which will be returned to him at the expiration of his term, and the labourer that he is under the joint guardianship of those men whose interest it is to make him feel that he is not forgotten in the arrangements that are made for the better fulfilment of the various obligations which are attendant upon any satisfactory solution of this great problem. In fact, it is a more equitable adjustment of the right of landlord and tenant that is required. The landlord should feel that his property will not depreciate, but may increase in value; the tenant that the capital expended is still his own as much as the owner who lays out money for improving his estate. And that the threefold cord that binds the interest of those directly engaged in the cultivation of the soil, the landlord, the tenant-farmer, and the labourer, may be strengthened and more firmly united by this and each future discussion of this important Club, is the earnest wish of your humble servant.

Mr. CADLE (Gloucester) said he was glad that they had had such an excellent paper. He was also pleased that Mr. Masfen had endorsed that evening many of the opinions expressed by himself in his essay for the Royal Agricultural Society. He took exception, indeed, to one point in his paper to-night, which appeared to him most important—that which had reference to superphosphate of lime. If a tenant is not allowed to sell off hay or straw without bringing an equivalent back to the farm, it was perfectly immaterial whether the manure was in the field or in the rick-yard. He saw no reason why the tenant should not be paid for more than last year's manures. If he used them for a crop of corn he would thereby increase it, and they all knew that the more the straw crop was increased the less likely the land was to be foul. As regarded leases he had seen so many disadvantages arising from them that he thought a system under which the tenant would be fairly compensated for improvement would be far better than a lease. Of course a twelvemonth's notice would not do away with the advantage of tenant-right. He certainly thought it was a great mistake to have an arrangement under which a man would first spend 10 or 15 years in getting a farm into a good state of cultivation, and then spend the next 5 or 6 years in undoing in this way all that had been previously done. Instead of a tenant recouping himself for what he had done, the landlord or incoming tenant ought to pay him for it, rather than allow the farm to be run out. In the case of a yearly tenancy the tenant should have an opportunity of getting back what he had invested, and how was that to be done without over-cropping or compensation? In this respect it was far better, he thought, for the outgoing tenant to be overpaid than not paid at all. Of course he would not put manure on the land when he knew he was going to leave unless he was to get something by it, and it should be made his interest to keep the land in good condition, so that his successor would share the benefit.

Mr. W. BROWN (Ting) said he had listened with much interest to the paper read by Mr. Masfen, and considered it, on the whole, a fair view of the question. At the same time, he must say that that gentleman had addressed himself far more to the question of the tenants' than to that of the landlords' interest. (A voice: "They are identical"). He (Mr. Brown) was not, he must observe, at the outset, a farmer, but a land-agent, and would remind them that there were bad tenants as well as bad landlords (Hear, hear). He had been several times in a court of law when evidence had been given with regard to questions of this kind, and when the judges and others concerned had said, in effect, to the landlords, "You had an opportunity when you were letting the farm of making any conditions you pleased, and if you did not take care of your-

self you must put up with the consequences." One great point connected with the discussion that evening was the want of capital. Some owners of large estates were in the habit of putting farms together, thus adding to the holding of those who, perhaps, had before great difficulty in carrying on what they already held in a proper manner. In that way hundreds of acres had in some cases been added to the occupations of farmers, not from their own free choice, but because that was the system adopted on certain estates in this kingdom, and it was one of the greatest hindrances to the advancement of agriculture that so many persons took land who had not the means of properly cultivating it (Hear, hear). With regard to farming agreements, Mr. Clinton, whose name would be received with respect in any public assembly as that of a man who was one of the greatest land agents in the kingdom (Hear, hear), had intimated to an institute of which he was a member that in his opinion the law of landlord and tenant must soon undergo alteration, and he suggested that, in the mean time, it was desirable that in every case there should be a contract which would prevent those disputes which arose out of what was called the custom of the country. He had himself seen illustrations of the necessity of a change in that respect. "The custom of the country" was the most indefinite description that could be conceived. Within a distance of 10 miles the customs differed so much that it was impossible to tell what they really were (Hear, hear). In a neighbourhood with which he was acquainted there was an agreement which had for the last 30 years been applied on an estate of four or five thousand acres, which after a mass of nonsense contained one clause to this effect, that the landlord agreed to allow the tenant at the end of the tenancy for all improvements of a permanent nature made on the farm, of which he had not reaped the full benefit (Hear, hear); such compensation to be settled in case of disagreement by arbitration (Hear, hear). He had never made an agreement since he first commenced business which did not provide for arbitration, the arrangement being that each party should appoint an arbitrator, that the arbitrators should appoint an umpire, and that in case these could not agree the arbitrator or umpire should be appointed by the under-sheriff of the county. As a land agent he might remark that on one occasion he was requested by a gentleman, a former member of this Club, to put a fair price upon a farm which had become vacant, and after having done so, he advertised the farm to let by tender, the result was a practical farmer in the district offered 8s. per acre more than his (Mr. Brown's) valuation (Hear, hear). It was the farmers as a body who raised the price of land, and not the land agents (Hear, hear). He could mention numerous instances in proof of that. He could not agree with the chairman that men ought to farm without restrictions. It was necessary to provide for the case of bad tenants as well as good ones (Hear, hear). He had never met with a case in which a landlord whose head was screwed on the right way found fault with a man for good farming. [Mr. T. CONGREVE: "The rent is raised"—Hear, hear.] It was only trumpery kind of people who did that. [Mr. MASFEN: "There are a good many of them"—Hear, hear.] Allusion had been made to payment for seeds. He had just had a case under his notice in Surrey, in which the tenant had to pay for seeds put down in grass land, the period extending back 20 years, no less than from 50s. to £3 an acre. As regarded the period for terminating tenancies, he thought Lady-day was far preferable to Michaelmas because it afforded less room for dispute. He had found the Lady-day arrangement a great convenience in Oxfordshire. At Lady-day when one man walked out and another walked in everything was easily settled by two men coming to the farm to value.

The CHAIRMAN observed that that was not the general custom in Oxfordshire.

Mr. BROWN continued: As regarded the drawing of leases; in many cases the reason why more practical clauses were not inserted, was that the matter was left to the family lawyer. An hon. baronet, whose predecessor was well known to everybody in England, having once consulted him about becoming his agent, told him that he was not to receive the rents, nor draw up agreements, as the lawyer would do this, neither did he wish him to interfere with the tenants, because they were a very respectable set of men, who always paid their rents regularly, adding that only one tenant, who was a book-farmer, had

ever given him any trouble (laughter). It appeared, in fact, that all Sir Robert wanted him for was to examine into demands for repairs, and hence he declined to act on his behalf. As regarded artificial manures, he contended that there were many which ought not to be paid for. Take, for example, the use of nitrate of soda. Of what benefit could that be to the incoming tenant. [A VOICE: "None."] As to cottage accommodation, he maintained that in the case of every farm the labourers ought to be enabled to reside within a convenient distance, and not compelled to walk two or three miles to their work, and that landlords should treat the question of cottages just as they dealt with that of farm-buildings. Labourers' cottages were strictly appendages to the farm. Game—one of the great questions of the day—had, as they must all feel, a very close connection with farm agreements. With regard to rabbits, he would say let them be annihilated, but as respected other kinds of game let farmers give all the encouragement they could to gentlemen who were fond of field sports (Hear, hear).

Mr. J. J. MECCHI (Tytree Hall, Essex) thought they were all quite agreed as to whose duty it was to effect certain improvements, as to what improvements should be made by the landlords, and what by the tenant. If a tenant had, as he had done, spent six or seven pounds an acre in draining perfectly heavy clay land, and five pounds an acre more in chalking it, and if he happened to die at the expiration of a short lease, by the custom in Essex not one shilling would be paid to his wife and family for the £12 thus expended. The custom of the county did not sanction that outlay, and hence nothing could be obtained. Drainage should be done by the landlord. Let him, if he liked, charge a per-centage upon it, but let not money expended by the tenant for such a purpose be taken from his capital. No one could doubt that the value of the land was greatly improved by drainage, and if, in order to secure good cultivation, the tenant was compelled to make the necessary outlay, he or his widow and children ought not to be deprived of the capital expended. Although he was called an apron-string farmer, he had farmed now for six-and-twenty years; and the drainage on his farm being as perfect now as when it was first made, no one could say that that was not a permanent improvement. He considered the discussion of such questions as that of great importance as respected agricultural progress. He believed that the great bulk of the landlords wished to do what was right, and he did not think that rents should always remain at the same amount. Considering the increase of population and of the general wealth of the country, it seemed to him only fair and equitable that if at the end of a twenty-one years' lease it turned out that the land had increased in value there should be a reasonable amount of increase of rent. The question of game was a very delicate one. He was a believer in the great value of winged game to farmers as destroyers of insects. He had generally three or four hundred fowls; they had access to every field on his farm, and within fifty feet of their home he had always the largest crop of corn (An exclamation: "The deuce you have!" followed by laughter). He was stating what he well knew to be a fact, and he still maintained that winged game were advantageous to crops (laughter). But when he came to rabbits and ground game that was another question. As an old sportsman he thought it was desirable to encourage landlords to reside on their estates, and not to tempt them to imitate the Irish absentees. Farmers ought to make everything agreeable to them, so far as they could do so consistently with justice and equity to themselves. But he wished to say that he had seen the worst farming round covers, and he thought that if there were one place where they ought to farm twice as well as they did anywhere else, if they wished to study their own interest, it was immediately round the covers (laughter). He was speaking cautiously and practically, having seen immediately round the covers some of the best crops on the farm (laughter). Again, if they wished to remain on good terms with their landlords, about £40 spent on wire netting might secure that object. The question of agreements between landlords and tenants was a very large question. Many of the agreements now in operation originated at a period when farming was in a totally different position from that which it occupied at present, and when it was not contemplated that farmers would buy large quantities of foreign cake and other articles for the purpose of making up the damage done by corn crops. He knew a farmer who expended £3,500 for

1,200 acres in that form. As to valuations for improvements, he felt that it must not be assumed that all farmers were honest. There were dishonest and unfair tenants as well as unreasonable and unjust landlords, and the grand point was to aim at securing a system which would ensure an equitable settlement of the claims of both classes (Hear, hear).

Mr. H. TRETHEWY (Silsoe, Ampthill) said: He would begin by endeavouring to answer the question put by Mr. Mechi. What improvements a landlord and what improvements a tenant should make? In his opinion that question was very easily answered. He thought that all such permanent improvements as Mr. Mechi alluded to, draining, building, and so on, should be made by the landlord, a fair per-centage being charged on the outlay, according to agreement. Everything of that kind resolved itself into a question of rent. If a farm were very low-rented, it would bear a per-centage upon improvements; and on the other hand, if it were very highly-rented, the same amount of burden could not be equitably imposed. For his own part he must say—and he had considerable experience in this matter for many years past, and had given evidence before a committee of the House of Commons, consistently with principles which he had acted upon ever since—he thought it was fair to charge under ordinary circumstances five per cent. for an outlay of that kind, and he thought such an arrangement was mutually advantageous to landlord and tenant. Chalking and liming were operations which should, in his opinion, be done by the tenant for obvious reasons. In the first place, the tenant probably found the chalk on the land; he had his own carts to cart it home with, and it would be as absurd for him to call upon the landlord to come and chalk the land for him, as it would to ask him to plough it. He thought the tenant should be compensated for marling or chalking; but he would not have the thing done by valuation. Many gentlemen might differ from him on that point, but he entertained a strong opinion, and had reasons for it. Before chalking or liming, or any operation of that kind was commenced, he would have an agreement with the tenant; he would say to him, "In the event of a change of occupation you shall be paid so much for your outlay in proportion to the advantage derived from it." That could be endorsed in an agreement, and in the event of death there was no difficulty in settling the matter. Such an arrangement did away with a great deal of unpleasantness and uncertainty, and at all events people knew what they were dealing with. Some people thought that a tenant should be paid for everything which he considered an improvement. What a tenant considered to be an improvement, a landlord might consider the reverse, and he (Mr. Trethewy) held that a landlord should not be called upon to pay for anything, unless he has been consulted. A tenant might take it into his head to set up a fence, or even a building, which in the landlord's opinion would be far from improving the farm. He thought that each party should be consulted in such matters, and that the landlord should not be required to pay for every improvement which the tenant might feel inclined to make. A great deal has been said lately about leases. Many persons thought leases were a panacea for all the evils complained of; they said "Give a tenant a lease, and then he is sure to farm well." His opinion was, that tenant-farming was better under a yearly agreement, with a compensation clause than under a lease without compensation (Hear, hear). With a seven or fourteen-years' lease there was almost always an increase of rent at the end of the period. Leases were the rule in Scotland, and what was the consequence? There was no other land in the kingdom which was rented so high.

Mr. T. CONGREVE: The leases are for 31 years (Hear, hear). Mr. TRETHEWY: He was well acquainted with several large estates in different counties, and he had found everywhere that where leases did not prevail, many occupations remained in the same family for generations, and that where leases prevailed there were frequent changes (Hear, hear). Another vexed question had been raised, through which he did not see his way. I sounded very feasible to say, as Mr. Mechi did, that all the hay and straw should be consumed on the farm, and that a certain proportion should be brought back; but he wanted to know how anyone could tell how many tons of cake or guano had gone off the farm, and how many should be brought there. His opinion was that the best farmers were those who consume their own hay and straw, and instead of selling bought. He said that unhesitatingly and fearlessly. Mr. Masfen whispered

and he thanked him for the hint, that that question depended a good deal on the situation of the farm. If a farm were near a town or a railway station, the occupier might be able to sell his hay or straw, and get back what he wanted for cultivation; but the case was totally different when four or five miles intervened—then the carting would beat them. As regarded game, he might remark that no man in that room perhaps had set himself more against ground game than he had done. He thought the tenant should be allowed to destroy the rabbits; but where the landlord lived on his estate, and reserved the right of shooting, and the farm was taken on that condition, the tenant could not blame his landlord for exercising his right. If a landlord had let his land on the understanding that the ground game should be reduced, then it was a most unjust thing for him to allow the estate to be over-run by it, and he thought that rabbits should under all circumstances be killed down. Mr. Mechi seemed to think it impossible for tenants to kill rabbits, because they got into the covers. In such cases landlords might employ a warrener to kill them.

Mr. T. CONGREVE: They never do it.

Mr. TRETHEWY begged Mr. Congreve's pardon for differing from him—some landlords had done it, and he (Mr. Trethewy) appealed to a gentleman sitting opposite to him whether he had not begged him to let him have one of his men to destroy rabbits in different counties where he had agencies.

Mr. EDMUNDS (Bugsby) said he could not help asking where they were—in other words, what was their position as farmers in relation to that question. What tended more than anything else to hinder the development of agriculture was, he believed, uncertainty of tenure, under which a man could not tell whether or not he would ever get back what he invested in the soil. In every farming agreement which he had seen yet, there was too much left to good feeling. In commerce nothing was left to good feeling—a man would not trust his own brother, but would have everything in black and white. As regarded agriculture, however, Mr. Jasper More and other gentlemen said, as he had observed lately, that no landlord would do this thing or the other, because good feeling would not let him. If good feeling existed everywhere, the tenant might be safe; but unfortunately it did not (Hear, hear). Where a landlord employed an agent, who was a good practical man of business, the tenants might practically be in a secure position; but there were cases in which noblemen left everything to a lawyer in London, who knew nothing about the tenants or their wants, and then there could be no security or improvement, because red tape ruled everything. As regarded forms of agreements, he should be glad to see something emanating from an authoritative body. There were the Royal Agricultural Society, the Chambers of Agriculture, and the Farmers' Club, either of which might deal with that question. He had more hope of the Farmers' Club in that respect than of either of the other societies. That Club consisted chiefly of men who were practical farmers and men of business; he did not know of what the other societies consisted, though he saw a great many big names connected with them. He thought that Club might draw up a form of agreement which would show what ought to be done. As to laying out seven or eight pounds an acre for chalking, as Mr. Mechi appeared to have done, without any security for compensation, if a man did that, he committed an act of folly, and deserved to lose his money (laughter). As to the poultry about which Mr. Mechi talked so much, he might remark that he kept a good deal of poultry on his farm, and he was sure that if they could have their own way they would eat all he grew (laughter). The land immediately round the covers ought in his opinion never to be let at all (Hear, hear); it belonged properly to the landlord, who kept the game to consume the crops.

Mr. L. A. COUSMAKER (Westwood, Guildford) said, being his own landlord and tenant he considered himself perfectly unprejudiced on that question, and having farmed for seven-and-thirty years, and kept his eyes open on all around him, he was not without experience. In the case of agreements generally there were only two parties; but in the present instance there were virtually three, and they had to consider not only what was best for landlord and tenant, but also what was best for the public at large. If a farm were let on certain conditions, which were strictly adhered to, neither of the immediate parties to the agreement could complain; but, then,

the third party to which he alluded might step in and inquire by what kind of agreement it would be likely to benefit most. Hence the question under discussion was, What was that form of agreement between two parties—landlord and tenant—from which a third party—the public—would derive the greatest advantage? He was against long leases, he thought they could not be advantageous to either party. A landlord who had granted a lease might soon find that he had for his tenant a man who was very different from what he had expected or hoped to find him. He might find a very bad farmer instead of a good one, or that he had got a good farmer but a very unpleasant fellow, and in neither case was he likely to feel satisfied. Such a state of things could not encourage landlords to do what was so desirable—reside on their estates. Even if the tenant were a desirable one, he might, of course, die, and the widow find herself saddled with a long lease. He thought that tenancy at will was the best mode of occupation, tending, as it did, to promote a good understanding between landlord and tenant. A good landlord would never refuse to good tenant any proper permanent improvements on his estate. Having satisfied himself that the things asked for would be improvements, it would be his duty to do one of two things—either to execute the improvements himself, charging the tenant a fair rate of interest for the outlay, or else to allow the tenant to execute them upon the security of a written agreement, that whenever he quitted the farm, whatever might be his interest in what had been done, he should receive compensation for it. No tenant occupying a farm on such conditions would be much aggrieved, and he believed that under such a state of things agriculture would advance much more than it would under a system of leases (Hear, hear).

Mr. C. S. READ, M.P., thought no one could doubt that whoever made improvements should be paid for them. As to the landlord, of course he would take care of himself; unless, indeed, he happened to be in the position shadowed forth by Mr. Trethewy, of having let his land at so high a rent that he could not possibly make any additional charge. As regarded the tenant, he did not agree with Mr. Trethewy that it should be necessary for him to go to his landlord and consult him about every improvement in the cultivation and management of the farm (Hear, hear). If a good system of Tenant-Right, similar to that in Lincolnshire, were established throughout the length and breadth of the land, there would be no necessity for the tenant to go to his landlord and say, "I want you to drain this field, and to chalk that one;" every man would then farm the land in the best possible manner, feeling satisfied that he or his representatives would some time or other reap the benefit (Hear, hear). No one could be more in favour of long leases than he was, having observed how much good they had done in his own county; and he felt convinced that if tenants received reasonable compensation for improvements, either through leases or a system of tenant-right, the agriculture of England would be rapidly advanced by that means (cheers). There were many things in Mr. Cadie's model agreement of which he entirely approved; but there were one or two which he could not endorse. In the first place, he objected very strongly to a six-months' notice to quit (Hear, hear). He objected to that short notice more every day he lived, not because he wished to give the tenant a greater chance of running out the land; but to give him a longer chance of finding some other occupation (Hear). Again, any agreement enforcing a Lady-day entry on arable land would be altogether wrong (Hear, hear); and any clause which reserved rabbits to the landlord would certainly be a great mistake (Hear, hear). If he were rightly informed, many farms in Scotland were at the end of the lease let by public tender, the outgoing tenant having no prior claim, whereas he thought the right way was to have an understanding at least two years before the lease expired as to a renewal of the term. He agreed with Mr. Trethewy that in parts of Scotland more changes of tenants took place where leases prevailed than in many districts of England where land was held at yearly tenancies. Considering the immense amount of capital embarked by the tenant farmer in the cultivation of the soil, and believing that in a few exceptional cases landlords took advantage of that want of security. He thought the time had arrived when a liberal and comprehensive system of Tenant-right should be extended over the whole country (cheers).

The Rev. E. SMYTHIES (Hathern Rectory, Loughborough) considered that this question was, after all, one simply of de-

mand and supply. A great deal of disputing and dissension arose from the fact that the demand for land greatly exceeded the supply, and those who were subject to the effects of excessive competition naturally disliked it. On a large estate with which he was acquainted the farms were very moderately rented, but they were very badly managed, and when his friends talked to the owner about making improvements, he replied that he did not know why he should trouble himself about them, seeing that if a farm happened to become vacant at 10 o'clock at night he had a dozen applications for it the next morning (Hear, hear). The truth was that a great many men who had piled up money in towns seemed anxious to lose it in the country, and that greatly increased the competition for farms, and the rents paid for them. Indeed, such persons as he alluded to hardly seemed to mind what rent they paid, while practical farmers had learnt by experience the necessity of caution. This question suffered through being overshadowed by a cloud of vague generalities. They constantly heard such phrases as "unexhausted improvements," "custom of the country," "duties of landlords," and so on. What did they mean? Let some one try to represent them by figures. No arrangement could be applicable in every county. Moreover the owners of the soil were many of them sadly ignorant as to what concerned their own interest. It was matter of fact that noble lords and hon. baronets who owned a large proportion of the soil of this country knew nothing about it; many of them actually prided themselves on their ignorance, and when questions arose they referred them to the family solicitor, who also knew nothing about the matter. Being himself once concerned in the letting of about 1,200 acres, he gave instructions that there should be no restrictions as to cropping, but the lease being drawn by the family solicitor he was obliged to yield to a certain extent to his representations that the usual covenant as to cropping should be inserted. The solicitor also objected to a stipulation which he desired giving to the tenant an absolute right as regarded sporting, but on that point he (Mr. Smythies) remained firm. What, however, was the result? Within one week after the agreement was signed the tenant advertised the game, and he let the whole to a London man at a shilling per acre; and it turned out that the lawyer was right and he was wrong. So that there was something to be said on the landlord's side as well as the tenant's as regarded game (Hear, hear). What Mr. Masfen said about education reminded him that it would be a great mistake to suppose that the farmers who met there and took part in the discussions constituted a fair representation of the farmers of this country. It was no flattery to say that they were, in fact, *la crème de la crème* (laughter); and he might add that they might find in almost any district a number of men who had never been near the Farmers' Club, and whose notions were very different from those entertained by the men whose position was sketched by Mr. Masfen (Hear, hear). There was an immense number of cultivators of land whose object seemed to be to get as much land as possible, no matter how small their capital, and who endeavoured, as it were, to save their rent rather than to make it (Hear, hear). Such persons were very apt to get into the *Gazette*, and to leave their farms in a far inferior state to that in which they found them. The better class of tenants ought to be allowed to use a farm as the miller used his mill, that is to make as much as they could by keeping it well oiled and in good working condition. In these days men could get artificial manures at a much cheaper rate than they could make manures on their own farm. He could not recall any period last year when straw was worth less than three guineas a ton. He himself sold some at four guineas, and would any practical man tell him that there was some process of making manure by which he could make straw manure worth that amount? (Hear, hear). He thought that men should be allowed to take advantage of an exceptional state of the markets. If landlords wanted to secure the right kind of men as tenants they must insist on there being sufficient capital. A good deal had been said that evening about the comparative merits of leases and tenancies year by year. Much had been and might be urged in favour of both. When there was the right sort of man let him have a lease. He might here remark that he had been told by a member of that Club of a case in which the same family had occupied under the same family ever since the Conquest. That spoke well for both.

A MEMBER: Was that under leases or an agreement?

The Rev. E. SMYTHIES replied that it was an annual tenancy. He would add, with regard to cottages, that landlords as well as tenants might be short of capital, and it was not an easy matter for an owner whose estate was deeply encumbered to provide all that was needed in regard to labourers' dwellings. He might fairly reply to appeals that he could not afford the requisite outlay.

Mr. G. H. HUSARY (Green Farm, High Wycombe) said that in from twelve to twenty cases in which farms had passed through his hands as an agent, the tenant having been offered the option of a lease terminable in seven or fourteen years or a two years' running agreement, had preferred the latter (Hear, hear). He thought that on no account should there be less than eighteen months' notice either from the landlord or the tenant. In speaking of improvements, several gentlemen had spoken of the landlords as if they all came under one category: it did not seem to have occurred to them that there was trust-property, and cases where the "landlord" had not the power to expend money on improvements. Where a landlord had the power he thought the fair plan was for the landlord and tenant to agree on the per-centage that should be repaid by the tenant for such permanent improvements, leaving the detail for subsequent arrangement, or that the landlord should supply the pipes (in the case of draining) and the tenant put them in at his own expense. In his opinion tenants should be allowed to sell wheat-straw, trefoil, sanfoin, and clover hay on bringing back manure equivalent to the manure which the hay and straw would have produced if consumed upon the farm. He did not see how without such an arrangement the London and other large markets could be supplied.

Mr. G. JACKSON (Tattenhall Hall, Chester) said it was nearly fourteen years since, as a member of that Club, he introduced the question, What form of agreement was best calculated to give a stimulus to agricultural improvement? They had been asked that evening where they were in relation to that question? In that respect he was exceedingly gratified with the discussion, showing as it did that they were far ahead of the position they were in when he read his paper in February, 1858 (Hear). At that period the subject was looked upon in the Club with great suspicion, and he met with little sympathy; but the case had been very different that evening. In Cheshire, it being felt that little could be done to improve agreements without the consent and approbation of landlords and agents, a committee was appointed, consisting of landlords, agents, and tenant-farmers, to consider the question. Three committee-meetings were held, each lasting about six hours. It was found that landlords were far more desirous of encouraging tenants in the path of improvement than had been anticipated; and the result was the framing of an agreement for Cheshire, which could hardly be improved upon (Hear, hear). If the farmers of each county in England would take that hint, and endeavour to collect together the landlords, agents, and tenant-farmers in their several localities, that would, he believed, tend greatly to establish tenant-right; and without tenant-right there could, as they all knew, be no farm-right. It was no use for one county to think of framing a form of agreement for another, for each locality required a separate kind of management; but he felt quite certain that, if what he had mentioned were carried out generally, they would soon have throughout England that kind of tenant-right which they were all so anxious to see.

The CHAIRMAN said before closing that discussion he felt it incumbent upon him to thank Mr. Masfen for his practical, and at the same time temperate, paper, containing as it did a vast amount of information well worthy the consideration and the serious attention of the members of the Club (cheers). He thought Mr. Cadle's opinion, that the condition of a farm should not be allowed to run out during the last years of a lease, was a correct one. Probably a notice for two years, with compensation for unexhausted manures used and improvements made during those two years, would answer the purpose of a lease. Mr. Brown's idea as to cottages on a farm also seemed to him correct. In speaking, as he did in his opening remarks, of no restrictions as to the course of cropping and the free use of the raw material, the land, he wished to be understood as having spoken of the modern and advanced and not of the slovenly farmer (Hear, hear). A good farmer farmed by growing restorative in rotation with exhaustive crops, and were he to do otherwise he would be cutting his own throat. Mr. Edmunds said, and said rightly, that too

much reliance was placed upon the good feelings existing between landlord and tenant. To his mind something more definite ought to exist through an equitable agreement being drawn-up as between the parties. Mr. Jackson's idea of forming a committee of landlords, agents, and tenants to discuss the question of an equitable agreement was a very sound one, and worth attention. The resources of the soil

could not be fully developed without either security of tenure or compensation for unexhausted improvements. The entire community were deeply interested in the proper solution of that problem.

Mr. MASFEN briefly replied, and this terminated the proceedings.

THE ANNUAL DINNER.

The took place on the Tuesday evening at the Salisbury Hotel, and was attended by nearly a hundred members and visitors. The chair was taken by Mr. R. J. Newton, president for the year, and the vice-chair, in the absence of Mr. James Howard, M.P., president elect for 1870 (in consequence of indisposition), was filled by the hon. member's brother, Mr. Charles Howard.

After an excellent dinner, grace was said by the Rev. Rowland Smith.

The CHAIRMAN gave the usual loyal and national toasts, Mr. J. DUMRELL responding for the Army, Navy, Militia, and Volunteers.

The CHAIRMAN rose and said that the next duty which devolved upon him was to propose what he presumed would be accepted as "the toast of the evening," namely, "Success to the Farmers' Club" (loud cheers). Happily this would not entail upon him much difficulty, as it would be seen by the Report submitted by the Committee to the Annual Meeting of Members, held that day, that the Club was in a very satisfactory position (cheers). Its receipts had never been higher in any previous year than the past, whilst the outgoings were considerably within the income. Many new members had been elected in the course of the year, and, fancifully speaking, the institution was altogether in a flourishing condition (cheers). The discussions which had taken place during the twelve months were of a useful character, and the subjects to which they related of great importance. The first was on the question of pauperism and vagrancy, which was commanding a large amount of attention out of doors at the present time; for, unhappily, both pauperism and vagrancy were largely on the increase in the country. The adulteration of cattle food and manures was the next subject, and more particularly concerned the members of the club, who belonged to the class that constituted the chief consumers of these articles. In the course of the discussion Dr. Voelcker explained which were the best sources whence to get them, and observed that the best and purest manures and foods were after all the cheapest: a remark which every practical man could appreciate and understand (Hear, hear). Passing on he came to a subject also of very great importance, though the discussion upon it took a different form from what many members anticipated it would take. It was introduced to the notice of the Club by Captain Dashwood, and it related to the different systems of rating as between England and Scotland. It appeared that the system in Scotland was based on the principle that one-half should be paid by the landlord, and one-half by the tenant, and this system had no doubt one good effect—that it increased the number of contributors to the rate and interested more persons in its proper expenditure (Hear, hear). The next subject to which their attention was directed was what he might term the Rabbit abuse (loud cries of "Hear"), the existence of which was the cause of much injury in many districts (Hear, hear). Foxes versus Rabbits was the title of the paper read; and he must say that, in the discussion which ensued, foxes had decidedly the best treatment of the two (Hear, hear, and laughter). They were good things in their way, by affording sport to the gentry and farmers; but as to rabbits, why they were an unmitigated evil (cheers). True, a reverend speaker complained that fox-hunting was carried to an excess, but at the same time it must be remembered that he had the candour to confess that having three boys growing up towards manhood he sent them fox-hunting whenever he could (loud cheers and laughter). The next subject on the card had been discussed so recently that it must be fresh in the minds of all present. It was raised on an interesting paper read by Mr. James Howard, the Member for Bedford, on

Continental Farming; but the only remark he would make on the subject was that Mr. Howard showed conclusively that the peasantry on the continent had to work harder and for less wages than our own labourers, and this was so far satisfactory, that it showed the English farmer did not object to pay his men a fair scale of wages. Mr. Howard pointed out, and Dr. Voelcker confirmed him, that there was a wide field open to the agriculture of this country for the growth of beet for the manufacture of sugar, and Dr. Voelcker also hinted that, although it was generally thought that the climate of England was unsuitable to the growth of beet for that purpose, this was altogether a mistake, and that as good beet-root could be grown here as elsewhere to make sugar (Hear, hear). With respect to the previous night's discussion on "the common form of farm agreement as tending to the fullest development of agriculture," he only hoped that some satisfactory result would follow from it; for on all hands it was admitted that something was wanted in the nature of a common form of agreement between landlord and tenant, and whatever that "something" might be, it was certainly for the interest alike of landlords, tenants, and labourers that the question should no longer remain unsettled. It was not in his power to point out what were the best means of doing this, but he was much struck by the statement of a Cheshire gentleman who spoke in the discussion and said that a committee had been formed in that county composed of landed proprietors, agents, and farmers, and that they had succeeded in settling an agreement so far as their county was concerned (Hear, hear). Whether a similar procedure in other counties might not be adopted with an equally good result was, he thought, well worthy of consideration (Hear, hear). Great success had attended the operations of the Club; moreover, through its discussions, helping to diffuse a general knowledge amongst the agricultural community by the agency of the Journal of the Club, and especially of the agricultural press, *Bell's Weekly Messenger* and the *Mark Lane Express*, papers which were also the means of spreading throughout the country a vast amount of useful agricultural information (loud cheers). That was not the only mode, however, in which the Club had exercised a beneficial influence; for it could not be doubted by members who had attended the meetings of the Club for a succession of years, as very many of them had done and he hoped would continue to do for years to come, that much practical information was interchanged in social chat both in the smoking-room and in the club-room, and he would venture to add that no man of ordinary intelligence could meet the members of the Club on any occasion without gaining information (Hear, hear). He thought he had now said enough to show that the success of the Farmers' Club of England was an accomplished fact (Hear, hear). That success was generally acknowledged, and the influence of the institution was gradually making itself felt in every way. Indeed he should not be saying too much if he added that opinions emanating from the Club were received by the press with greatly increased favour as compared with a few years ago. Why, that great organ for the diffusion of knowledge, the *Times*, recognized the utility and value of many of their discussions—an unmistakable sign of the success which had attended their efforts (Hear, hear). In the course of the past year members of the Club had gone as deputations to the Privy Council to express their views and opinions upon matters which deeply affected the agricultural interest, and he was happy to be able to say that those deputations had been received with courtesy and their opinions treated with marked respect by Mr. Forster, the vice-president of the Committee of Council. Further, the opinions of members of the Club had been asked on several occasions by per-

sons in high authority—which was an additional proof of the high position the Club occupied, and justified him in the assertion that as an institution it never stood in a better position than at the present moment (Hear, hear). In conclusion, he called upon the company to drink in a bumper “Success to the Farmers’ Club.”

The toast was drunk with immense applause.

Mr. A. PELL, M.P., in proposing the health of Mr. Newton—the chairman, said he had attended most, if not all, the meetings of the club held in that room during the year just closing; he felt entitled therefore to speak with some confidence respecting the manner in which Mr. Newton had performed the duties of his office; and he was prepared to say that a more business-like, intelligent, winning, and, he might add, commanding chairman in keeping an audience in order and promoting the transaction of business it had never been his good fortune to meet (cheers). And how was it they had come to find those qualities in their chairman? It was simply because he was no mere theorist, but had devoted the best years of his life to the business with which the name of the club was associated, that he was able in his riper days to preside over their deliberations and show how ably and well a practical man could conduct a business into which theory also entered largely (cheers). For many years, and he hoped for many yet to come, practice in this country had not had to retire into a place secondary to that of theory. We had seen enough of that in its most hideous colours in a country over the water, and he thought we might see there too that it was not unlikely to bring these simple pursuits to grief, if not to destruction. In England, at all events, we gave respect and a hearing to men who, like the chairman, had proved by the manner in which they have conducted their business that they were entitled to a hearing and respect, and that their opinion was of value (Hear, hear). It had not been his privilege to know Mr. Newton beyond the circle of his official sphere, but all that he had ever heard of his hon. friend confirmed his own impression that he was a right-down good, practical farmer; and, if he were that, then he must be to all of them a teacher and a benefactor (Hear, hear). He had been very much amused that morning on his visit to the Smithfield Club Show by going into one of the side rooms which branched off from the ground floor, where he found himself in a place which appeared to him to be devoted, if he might say so, to “the period in which we live” (a laugh). In that room, having previously secured his watch and deposited what little bit of chain he had in his waistcoat pocket (continued laughter), for there was a great crowd assembled, he found himself all at once brought up before a creation which called itself the “Little Wanzer,” and which he discovered was a sewing-machine. A little lower down he came to the “Gold of the Period,” but what that was he did not know. Passing on, he next came to the “Pump of the Period,” and he need scarcely say that in every direction the “Girl of the Period” was to be seen pressing upon the visitors rather severely (loud laughter). But it struck him as he looked around that what was still wanting there was a “Chairman of the Period” such as this club had the honour of possessing in the gentleman at the head of the table, whose health he begged to propose, not only as chairman of the Central Farmers’ Club, but as a model chairman of the period (loud cheers).

The CHAIRMAN briefly returned thanks, and in doing so expressed his acknowledgments for the ready and useful assistance he had received during his presidential year, from the Committee and the secretary, Mr. Corbet; while, in resigning the chair of the Club, he hoped he should do so with the conviction in all their minds that the honour of the post had not suffered at his hands (cheers).

Mr. T. HORLEY, jun., proposed as the next toast, “The Royal Agricultural Society of England, the Highland Society of Scotland, and the Royal Agricultural Society of Ireland.” There might possibly be a difference of opinion as to whether these societies had achieved the greatest possible amount of good in their power, and particularly he referred to the Royal Agricultural Society of England; but when they called to mind the first county show of that society at Oxford, in 1839, and looked back a few months to the last meeting at Manchester, the magnitude of the Show on that occasion, and the interest which it excited among all classes of the community, it was obvious that a great deal must have been done by the Society’s agency (Hear, hear). Then, taking a glance forward at the meeting

to be held at Oxford in 1870, and comparing what it would probably be with that which was held in the same place thirty-one years ago, he was sure all would admit that a vast stride had been made in the interest of agriculture by the institution to which he alluded. At the time of the first show at Oxford, all the people who could be collected were contained in the quadrangle of one of the colleges; and the question which he now put to himself was, what they would do with the multitudes that were likely to gather in Oxford at the Society’s Show in July 1870 (Hear, hear). On the whole he came to the conclusion that, although the Society might not have done all that was expected from it, nevertheless a great deal had been done. With regard to the Highland Society of Scotland, he gathered from its reports that it had made considerable progress, and been of great service to the agricultural interests in that part of the kingdom, and he felt sure that our Scottish brethren would always continue to be “up to the mark.” As to the Royal Agricultural Society of Ireland, he knew a little about that himself, and was aware that it had been very successful in promoting the advancement of agricultural improvement. One of the finest collections of roots that he ever saw was sent over to the English Society’s exhibition by the Irish Society. Subsequently it had been his lot to visit the shows of that society several times, and he ventured to say that the Roscommon sheep were very fine flesh and wool bearers. Expressing a hope that brighter times were in reserve for the sister country, Mr. Horley concluded by giving success to the three great associations of the United Kingdom, with which he joined the name of Mr. John Thompson (loud cheers).

Mr. THOMPSON responded, and said that he had had some little connection with the Highland Society of Scotland in his younger days; but as nearly a quarter of a century had passed since he crossed the Tweed, and settled in England, he regretted to say that he had not been able to keep up that connection as he should wish to have done. As a humble member of the Royal Agricultural Society of England he had great pleasure in acknowledging the toast, and he believed he might safely say, though it was hardly necessary to do so after what had fallen from Mr. Horley, that the history of that society from first to last was one of continued progress. Moreover, he also thought, notwithstanding all that had been said about exclusive management, favouritism, and so forth, that there was no body of men more anxious to do their duty, and conduct the business of a society in accordance with the requirements of the present age, than the existing Council of the Royal Agricultural Society. For his part, however, he should like to see a closer connection established between the Royal Agricultural Society and the local associations of the country (Hear, hear). He felt that it would be infinitely for the advantage of agriculture generally, if such a connection were effected, so that the local societies might form as it were the branches, and the central society the trunk of the great agricultural tree; and the circulation of knowledge, based upon the principles of practice with science, kept going throughout all parts of the country, for he could not see how the benefits they were all anxious to disseminate could reach the smaller tenantry and labourers without the agency of the local societies (cheers). He knew there were difficulties in the way of forming a union of the sort; but once that it was properly established and cemented, he was satisfied that it would be productive of great and wide-spread advantages (cheers).

Mr. GARNETT, in responding for “The Royal Agricultural Society of Ireland,” said he felt it a great privilege and pleasure to be associated that evening with the farmers of England, which was owing to the fact that his friends Mr. Read and Mr. Pell had visited his poor country, which was now in such an anomalous position, in order to judge for themselves as to what were its real resources. It had, in fact, enough agricultural resources to be a worthy rival of England. The Times had sent through the country a gentleman whom it called its private correspondent, the object being, he supposed, to obtain information for the guidance of Parliament in the coming session. Whom had it selected for that purpose? He had no wish to say anything offensive; but this correspondent was, he believed, a briefcase barrister, and a man who was as incapable of telling the public what was the nature of the soil, or for what kind of cultivation it was best adapted, as the smallest child in the city of London (laughter). This gentleman went from town to town and from village to village, picking up information

here and there for those who, he regretted to say, had never proved themselves the real friends of Ireland (Hear, hear). How differently did his friends Mr. Read and Mr. Pell act! They went to those parts of Ireland which formed the nursery for young stock—he regretted that they did not become better acquainted with the localities where it was brought to maturity; and, although they visited some of what might be called the worst parts of the country, if the *Times* correspondent was to be regarded as an authority, yet he ventured to say they met with no insult (cheers). It was the object of a certain party, for some political purpose, to keep Englishmen out of Ireland; but agriculturists were glad to see them whenever they came. The next meeting of the Royal Agricultural Society of Ireland was to be held in the far-famed town of Ballinaloe, which stood almost unrivalled as regarded the show of both sheep and cattle. He might here observe that his friend Mr. Read was so enamoured of the Roscommon heifers that he invested in them very largely; he bought no less than seven of them, and they were such animals that when his friends in Norfolk saw them they could hardly believe that they came from poor Ireland, fancying that they must have come from the Yorkshire volds, or some locality in which the huge Shorthorns were produced. Ireland produced as good cattle as good sheep, and as good roots as any other part of the kingdom; and, notwithstanding the Fenian disturbances, he believed the population generally would prove well-disposed if it were only properly treated and governed (cheers). The Irish agriculturists wanted to see English farmers among them (cheers). They did not care about seeing lawyers, who were interested in the continuance of dissension and discussion, which helped to make breach and bring business (laughter). He thought that the people of England should insist that if a Land Bill were passed for Ireland in the next session there should also be one for England. The countries forming the United Kingdom should not be dealt with as if they were separate; there should be one kind of legislation for all. They were all under the same authority; there was the same Government; the same Queen—God bless her! and he trusted that her Majesty would never forget what placed her on the throne, and would not consent to the Constitution being frittered away. In his opinion a crisis had come when they must all stand together as one man, for if Ireland went, England must go too (Hear, hear). There was a democratic spirit abroad, which must be resisted; but if all true patriots were firmly united, they would, through God's help, be enabled to maintain the empire in the position in which their forefathers placed it (cheers).

Mr. C. SWELL READ, M.P., on rising to propose "The Vice-Chairman of the Club," Mr. James Howard, M.P., said, At this our annual dinner almost everybody seems disposed to take a sort of retrospect of the closing year; and, as you have given me such a kind reception, you will, perhaps, before I proceed to the toast, allow me to take a little retrospect of Parliamentary matters in connection with agriculture (cheers). You may naturally ask what the agricultural members did for the farmers in the last session. Well, if you judge us by results, I fear I must reply "Precious little" (laughter); but if you will judge us by our earnest and hearty desire, I hope we shall have a favourable verdict at your hands. Never was it more true than it is at present that the minority is always in the right (laughter). We agricultural members happen to be a minority in the House, and we cannot be responsible for the doings of a tyrant majority. In the last session of Parliament I took upon myself on two occasions the great responsibility of dividing the House. The first question on which I divided was comparatively a very small and insignificant one; but as I believe I was right, I hope my conduct met with your approval. I wished, and I believe you wished too, that all servant boys under sixteen years of age should be exempt from taxation in that capacity. I do not know, indeed, that it might not be a very good thing for masters if the employment of such persons were taxed very highly, for there is not a more disagreeable set of persons to be found than stable-boys; but, on the other hand, considering how long it takes to teach such lads to perform their duties properly, it seems rather hard that masters should have to pay a tax of 15s. for the trouble they have with them (laughter). On another and more important occasion I divided the House on the question of the establishment of a separate market for the sale and slaughter of foreign stock; and, although we agricultural members were not successful in that division, sub-

sequent events have tended to prove, not only to the farming interest but to the nation at large, that we were in the right and the Government in the wrong (cheers). One word as to the future. In the first speech which I made in the House of Commons I said, in reply to a taunt which was thrown out against the agriculturists, that the farmers would never be the persons to call for protection again (Hear, hear). I then ventured to say that the skilled artisans and the manufacturers would ask for the restoration of protection long before we should think of doing so (cheers). Free trade is a very good game as long as it "beggars your neighbour;" but when it beggars yourself it is not so pleasant (Hear, hear, and laughter). As long as those who were engaged in the manufactures of this country begged the farmers they thought free trade uncommon nice (laughter); but now that it has had the effect of considerably reducing the wages of the artisans, such persons naturally think it is not quite so pleasant as it was at one time. I hope and trust that we farmers shall never be humbugged by protection any more (cheers). Let us go in for thorough and complete free trade—free trade seen not only in the abolition of import duties but in the right to buy and sell, convert, and manufacture all our produce in the manner which we consider best for our own interests (loud cheers). And now, gentlemen, for the toast which I have undertaken to propose, which is our future President, Mr. James Howard (cheers). I regard that gentleman not merely as a double-barrelled gun but as a regular revolver (laughter). In Parliament he is, in my opinion, a great weight and an immense benefit to agriculturists. One evening, after I had made a speech in the House, and Mr. Howard, besides endorsing all I had said, had added some useful, valuable, and pertinent statistics, a member from the other side came over to me and said, "You are, of course, a very respectable person, we, on the other side, like to hear you speak, and we give you great credit for sincerity; though all you fellows connected with the land have such narrow-minded notions. But," he went on to say, "there is that Mr. Howard, who sits on our side, let him say what he will, with his liberal politics, and that enlightenment which commercial enterprise gives a man, we seem to fancy that what he says must be true" (laughter). It is, gentlemen, on questions connected with the land that Mr. Howard will help us in the House of Commons. If in the next session a philosopher gets up to talk about peasant-proprietors, one of Mr. Howard's barrels will, I believe, go off and double that man up (laughter). Let politicians talk wildly on any subject connected with agriculture, and Mr. Howard will bring forth his practical experience to refute him. One evening last session, when there was a debate on the Patent Laws, and that great man Sir Roundell Palmer and that other great man Lord Stanley had denounced the Patent Laws, up got Mr. Howard and abolished the legal arguments of the one and the philosophical arguments of the other in the most charming and beautiful way (cheers). A gentleman who was sitting behind me said, "Well, that Liberal man on the other side of the House seems to me to knock those great dons over just as if they were ninepins, and this he does while he is beaming with good-nature and his face is as radiant as that of a cherub" (laughter). Mr. Howard's calm and collected manner, his thorough independence, and his practical knowledge of farming matters, combined as it is with a large degree of commercial intelligence, cannot but prove of the greatest service in Parliament to the agricultural interest; and I believe that at such a crisis as this you could not possibly have selected a more worthy or valuable person to be the president of your club (cheers). There are men who are so good that they will probably work themselves up; certainly they will never rust up; and I think perhaps our good friend Mr. James Howard, who is supposed to have been taking his holiday quietly and calmly, has in fact been doing rather more work than he should have done. It grieves me, and I am sure it will grieve all of you, to know that at the present time Mr. Howard's health is such that it would not allow him to be with us this evening; but let us drink with all enthusiasm his health—his better health (cheers)—and his future prosperity; and let us hope that he will be enabled at all times throughout the coming year to preside over the meetings of the Farmers' Club (cheers).

Mr. CHARLES HOWARD, in responding for his brother Mr. James Howard, observed that the state of his brother's health was such that his medical adviser had urged him to lay by for

a few days, but he (Mr. C. Howard) trusted that the indisposition was only of a temporary nature, and that he would shortly be able to resume his ordinary avocations (cheers). He felt very much indebted to Mr. Read for the kind manner in which he had proposed his brother's health, and he could only say that no one was more sensible of the honour conferred upon him by his election to the office of Chairman of the Club than his brother himself (Hear, hear). His brother was essentially an agriculturist; and although perhaps he might not be, strictly speaking, an agricultural member, or a member of what was called the country party in the House, yet he believed no agricultural member or member of the country party could feel more alive to the interests of farmers than his brother did, and he would add that he should not believe in him unless that were the case (cheers and laughter). Not that his brother had not done very much himself for agriculture—he was sure they would all give him credit for that (cheers), but agriculture had done very much more for him (laughter). It was to agriculture that he owed his present proud position, and he felt quite sure that when matters affecting the agricultural interest came before the House of Commons, although he held political views somewhat different from those of his friend Mr. Read, he would be found doing all he could on behalf of agriculturists. He (Mr. C. Howard) could tell them that there was in fact very little difference of opinion on many subjects between Mr. Read and his brother. They sat, indeed, on opposite sides of the House, but when they got down to the smoking-room it was "Hail, fellow, well met" (laughter), and the difference manifest in the House was no longer visible (laughter). They had heard a great deal as farmers about what Parliament was going to do for agriculture, and how many agricultural members and members of the press were striving to promote their interest. He had been engaged in agriculture now for about five-and-twenty years, and during that period there had always been somebody who was going to help the farmer; but he did not know that the farmer had derived much benefit from help of that kind. In his opinion that had been tried long enough, and farmers should now help themselves (cheers). Hitherto they had relied too much on assistance from extraneous sources, and they must now help themselves a little (cheers). If men would take game farms, or farms on which they would have to trust to the kindness of the owner instead of having the security of a proper agreement, let them not afterwards ask the public to assist them on the ground that they were not properly treated. In conclusion he had to propose "The Smithfield Club," and in doing so he would observe in reference to some remarks made by the Chairman at the Club dinner on the previous day about the small amount of stock produced on many farms, that if landlords would be more careful to select men of skill and capital to occupy their farms, instead of accepting as tenants those who offered the highest rent, not only would more corn be produced and the land be better cultivated, but there would also be more food, in the form of cattle and sheep for the people.

Mr. BUCKLEY briefly responded for the Smithfield Club; and Mr. TREADWELL having given "The Committee of Management,"

Mr. COUSSEMAKER, after returning thanks, proposed "The Secretary," Mr. H. Corbet, and observed that the Club was most fortunate in having had for two-and-twenty years such an efficient officer to represent it (cheers).

Mr. H. CORBET, who was received with cordial and prolonged cheers, said if he consulted his own feelings only, he should content himself with returning thanks in two words; but as the officer of the Farmers' Club, he wished to say something about the position which it occupied in relation to agriculture. For a great many years it was the special weakness of the farmers of England that they had no representation, whereas the attendance of that evening spoke to a different state of things. There was the honourable member for Leicestershire (Mr. Albert Pell), and he saw one of its most respected members in the person of the honourable member for Norfolk, Mr. C. S. Read. He found that whenever any agricultural question had to be settled, whether the Government were Whig or Tory, Radical or Conservative—whatever those mysterious terms might mean (laughter)—the honourable member for Norfolk was consulted, while,

as regarded the Government side of the House, if a politician had to be knocked down, or a philosopher confronted on an agricultural question, there was the honourable member for Bedford ready to do it (laughter). Thus in the Chairman of the Club in the past and the Chairman in the future they were well represented in the House of Commons. As regarded the discussion of the previous evening, he could not help remarking he was more than surprised at some of the things to which he listened. For example, he heard one gentleman remark, in effect, that the question of tenant's right or tenant's improvements, was just being taken up by the Farmers' Club! That reminded him of the character of Rip Van Winkle: he would not say where the "Sleepy Hollow" was (laughter). It would appear that many members of that club had no idea of what it had really done in past times (Hear, hear). On the previous evening doubts were expressed as to whether anybody could distinguish between durable and temporary, or in other words, landlords' and tenants' improvements. Twenty years ago, as was shown by a Blue Book, the Farmers' Club did that: it then distinctly drew a line between landlords' and tenants' improvements (Hear, hear), and yet gentlemen now spoke as if they were utterly ignorant that this had been done. One gentleman suggested that the Farmers' Club should attempt to draw up a form of agreement. He (Mr. Corbet) hoped that the last thing that club would do would be to try and draw up a form of agreement which would suit all the counties of England (Hear, hear, and cheers). A Shropshire Society attempted that, and with the most lamentable result; the attempt of a Suffolk Society was an equal failure; and though the Royal Agricultural Society of England gave a prize to Mr. Cadle for an essay having the same object, he would assert, Mr. Masfen notwithstanding, that again the result was lamentable (Hear, hear). If he (Mr. Corbet) wanted to set up a shuttlecock for everybody to knock about he would draw up a model agreement (laughter). The most valuable evidence on this subject was laid before a Committee of the House of Commons in 1848, at the instance of that club, and it might still be referred to. It had struck him, and the idea had been in his mind for some years, that it would be desirable to make a digest of all the discussions of that club, extending over about twenty-five years, for reference on agricultural matters (Hear, hear). He could scarcely conceive anything more valuable, and the only thing which had prevented him from making such a digest himself was a doubt whether, instead of occupying only a volume, it would not run to a number of volumes. He believed that club never stood in such a good position as it did then (cheers).

The concluding toast was "The Visitors," for whom Mr. Garnet briefly returned thanks.

DEATH OF MR. ANTHONY HAMOND.

This well-known agriculturist and Norfolk Squire died at West Acre, in that county, on Monday, Dec. 13, at the comparatively early age of sixty-four; for he was until lately a burly hale looking man. He was elected a Member of the Council of the Royal Agricultural Society in 1848, and had for the last twenty years been a prominent figure at the Council meetings in London and the annual shows in the country. Mr. Hamond was a man of much ability, seasoned by a sarcastic humour peculiarly his own, and there were few greater treats than to hear him "roast" his dear friends and neighbours, or "thump London strangers" at meetings in his own county. His keen wit scarcely tended to make him popular, and he offered himself again and again, but always in vain, as a Liberal representative of his own county. Nevertheless, what he said was always the point, and long before the game abuse had reached its crisis it has now, he denounced his brother squires as "fast degenerating into poulterers. Game had become a commercial affair and he hoped that the system would soon end in thorough bankruptcy." Mr. Hamond, however, was a sportsman at heart and his son and heir, by a sister of the famous John Musters is now Master of the West Norfolk fox-hounds.

THE CENTRAL CHAMBER OF AGRICULTURE.

A meeting of the Council of the Chamber of Agriculture, followed by the annual meeting of the Chamber itself, took place on Wednesday, December 8, at the Salisbury Hotel; Mr. C. Sewell Read, M.P., presiding at both meetings.

At the Council meeting a balance-sheet was presented, which showed a balance at the bank of £265 2s. 7d., independently of £31 in the hands of the Secretary. £36 of arrears was, it was stated, due from district chambers—a statement which created surprise and dissatisfaction in the meeting. The Treasurer and Secretary were re-elected; and some discussion ensued as to the connection of one of them with some journal, but no explanation was offered as to the Sub-Secretary's connection with the *Daily Telegraph*.

The draft Report, prepared for presentation to the annual meeting of the Chamber, was then read.

Mr. T. WILLSON having moved, and Mr. HORLEY, jun., having seconded the adoption of the Report,

Mr. GEORGE ANDREWS moved the insertion in it of the following: "That, notwithstanding the increase of the number of members, and the means of the Chamber, the Council feel that the subscription list at present represents very inadequately the great body of the owners and occupiers of England and Wales." He remarked that the number of members was under 200; a state of things which he considered very unsatisfactory.

The resolution having been seconded, after a short discussion was negatived, and the Report was then adopted, as prepared by the Business Committee.

The annual meeting of the Chamber followed immediately after.

The following Report of the Council before referred to was presented:

The Report stated that the progress of the Chambers of Agriculture during the past year had consisted chiefly in consolidating and extending the influence of the organizations which sprang rapidly into existence in the years 1867 and 1868. Thus, while all the chambers had added to their power by gathering in many new supporters, the two important ones of Cheshire and Monmouthshire had doubled their list of members within twelve months; the Banbury and the Herefordshire Chambers had increased to the extent of two-thirds; the Peterborough and the Warwickshire Chambers had grown one-fourth; the Leicestershire Chamber had added one-sixth, and the Essex and Worcestershire Chambers one-seventh. The work of planting centres had also been proceeded with, so that five chambers had been placed on the list since the issue of last year's report; while active measures were now in progress for the establishment of new chambers in several counties, and the Chamber of Agriculture movement had also been set on foot in Ireland. The number of members in the provincial chambers actually reported to the Council early in the year was 14,500, and, allowing for an increase up to the present time and for eleven chambers which had not returned the precise number of their members, the total constituency of the Chambers of Agriculture at the close of this year was probably upwards of 17,000, and the collective annual income of the chambers £3,000 or £9,000. There were now 71 chambers and branch chambers, of which 51 had contributed during the year to the funds of the Central Council a total sum of £245, entitling them to send 100 deputed members to the Council meetings. The Council, therefore, was at present composed of 100 members representing the provincial chambers, together with 26 members elected by the subscription members of the Central Chamber. To the total sum of £245 furnished by the provincial chambers, the subscription members of the Central Chamber added about £185, making the total income of the Council for the year about £430, being an improvement of about £65, or nearly one-fifth over that of last year. The Council acknowledged with satisfaction the valuable aid of the Press, particularly of the agricultural newspapers, in reporting the proceedings of the Chamber and the meetings of the Council. Having glanced at the subjects discussed in the course of the year, the action of the Council with reference to

local taxation and the present aspect of that question, the measures taken in promoting the successful opposition to the Valuation of Property Bill, and the passing of the County Administration Bill and the Adulteration of Seeds Bill, and having enunciated the views of the Council and Chamber on the malt-tax, the over-preservation of ground game, the existing method of taking the corn averages, and a uniform system of weights and measures, the Report mentioned that the resolutions of the Council on the subject of corn averages and weights and measures on being forwarded to the Board of Trade elicited the following answer from that department of the Government:—

"Statistical Department, Board of Trade,

"Nov. 26th, 1869.

"SIR,—I am directed by the Lords of the Committee of Privy Council for Trade to acknowledge the receipt of your letter of the 9th inst., forwarding a copy of resolutions passed unanimously by the deputed members of the Chambers of Agriculture, at a Council Meeting of the Central Chamber, upon the system of taking the corn averages, and upon the mode of selling corn. And I am to request you to be good enough to inform the Council of the Central Chamber of Agriculture that, as regards the corn averages, the Government will be ready to pay every attention to representations respecting the operation of the system of taking the corn averages, and will carefully consider any proposed change of the system that may be deemed equitable by the payers and receivers of tithes; and, with reference to the mode of selling corn, that, as the subject of weights and measures of the United Kingdom is before the Commissioners appointed to inquire into the condition of the Exchequer Standards, a copy of the resolutions of the Chamber bearing upon the standards for the sale of corn shall be forwarded to the Standards Commission for their consideration.

"I am, Sir, your obedient servant,

"R. W. FONBLANQUE."

The Report further enumerated the steps taken by the Council with reference to the importation of foreign cattle and the measure proposed by the Government, which subsequently became law, for the prevention of the spread of contagious diseases amongst home-bred stock. The Council add the expression of their "regret that, notwithstanding the strenuous efforts of their friends on both sides of the House, so few of their proposed amendments were accepted by the Government. The bill as passed leaves the whole action and responsibility of regulating the import of foreign stock in the hands of the Privy Council, and the way in which those duties have been performed may be gathered from the fact that foreign sheep which have been associated with diseased animals were allowed to go into the country, and have caused the fearful outbreak of foot-and-mouth disease from which the agricultural interest is now suffering."

Mr. T. WILLSON moved that Sir Massey Lopes, M.P., be the Vice-Chairman for 1870.

Mr. ELLIS seconded the motion, and it was passed unanimously.

The following were elected to fill the vacancies caused by the retirement of eight members of the Council by rotation, the first six being retiring members re-elected, and the last two new members:

Mr. R. Masfen, of Pendeford, Wolverhampton.

Mr. R. J. More, of Linley Hall, Bishop's Castle.

Mr. A. Poll, M.P., of Hazelbeach Hill, Northampton.

Mr. C. Sewell Read, M.P., Honingham Thorpe, Norwich.

Mr. E. Riley, of Kipling-cotes Farm, Beverley.

Mr. J. Smyth, of Newells Bury, Royston, Herts.

Capt. P. G. Craigie, of Partney Grange, Lincolnshire.

Mr. T. Rigby, of Over Winsford, Middlewich.

The auditors having been reappointed,

Mr. DANIEL LONG moved, in pursuance of notice, that retiring members of Council shall not be eligible for re-election for one year. He thought that such an arrangement would

tend to increase the subscriptions; while, as regarded the objection that it might deprive the Chamber of the services of valuable members of Council, he remarked that such gentlemen might still be deputed members.

The motion, having been opposed, was negatived, 8 hands being held up for, and 22 against it.

Sir M. LOPES, M.P., as chairman of the local taxation committee, presented the following report: "The questions embraced by what is commonly spoken of as local taxation have been before the country and the legislature for several years, and in 1850 a committee of the House of Lords decided that the relief of the poor was a national object, towards which every description of property ought to contribute. Not only has this charge now considerably increased, but additional burdens—such as police, highways, vaccination, registration, lunatics, militia stores, shire halls—have greatly aggravated the amount, and multiplied the objects of local taxation. Until the formation of the Central Chamber no great prominence was given to the consideration of this question, although the necessity for fresh legislation had been affirmed by the high authority of the House of Lords. The Central Chamber, formed in 1867, considered this question one of the greatest grievances which the agricultural interest was subjected to, affirmed the injustice of the present system of local taxation, and urged the chambers throughout the country to take up the question. This was done with alacrity, and during the past two years no question has been more extensively canvassed, and upon no one does there prevail such unanimity of opinion. The Somerset Chamber took up a leading position in the matter, and, after discussing the subject, a copy of their resolutions was forwarded to every chamber in the country. In February, 1868, Sir M. E. H. Beach moved in the House of Commons for a return on local taxation. In May, the same year, Sir Massey Lopes brought the question prominently before the House, and in June Mr. Corrance moved for a select committee; but, owing to the lateness of the session, the motion was, after an animated discussion, withdrawn. Again, in July, 1868, having previously been discussed by almost every Chamber in the United Kingdom, the question was finally brought before the Central Chamber at Leicester, on a motion by Sir George Jenkinson. On the proposition of Mr. Pell, the following resolution was passed: 'That a committee of the House of Lords in the year 1850, having decided that the relief of the poor is a national object towards which every description of property ought to contribute, this meeting recommends the chambers of agriculture to support by every means in their power legislation for carrying the principle into effect.' The resolutions passed by the chambers were very ably condensed in two of the resolutions presented at the interview of the deputation from the Central Chamber with Mr. Gladstone on the questions, viz.: (1) 'That the unequal pressure of the poor-rate, as at present imposed, is a grievance which renders necessary the early and serious consideration of Parliament.' (2) 'That the maintenance of the poor is a national liability, to which income from every source should contribute.' It will be remembered that the opinions of the chambers were forcibly set before Mr. Gladstone by Mr. C. S. Read, M.P., Mr. Randall, of Lincolnshire, Mr. Hodson, of West Kent, Captain Craigie, and Mr. Thomas Duckham. At the commencement of his reply, Mr. Gladstone said, 'I was very anxious you should feel assured we were very sensible of an imperative obligation to give our best attention to a matter of such importance;' and finally he added, 'I fully agree with Mr. Read that it is a question which is entitled to the gravest consideration, apart from political parties.' A month elapsed, and then upon the motion for a royal commission, moved by Sir Massey Lopes, the ministers had an opportunity of giving a more deliberate reply to the questions previously submitted. After the discussion on the motion, Mr. Goschen admitted that the question, which affected both town and country equally, must be dealt with speedily. It occupied now the attention of the Government; but it must be dealt with by Parliament, and not by an irresponsible tribunal like a royal commission, one result of which, he pointed out, would be to hang the question up indefinitely. After some further discussion, Mr. Gladstone said the motion was one which recommended itself by every motive which could address itself to the indolence and indifference of an administration; because, if the Government were to accept that motion and appoint a commission for the purpose recommended by the hon. baronet, it would give the

Government a lease of several years' peace and tranquility in reference to the discussion of the matter. As regarded the suggestions of one or two hon. gentlemen that a committee of that House should be appointed, he would only say that he looked upon the subject as beyond the range and scope of a committee, and he could not forbear from expressing the opinion that the Government would be in a manner shrinking from their just responsibility were they to propose a general relegation of the question to a select committee. He hoped it would be understood from his remarks that the Government was by no means insensible of the importance, and he would even say of the urgency of the question; and, if indisposed to accede to the motion of the hon. member, it was not because it was indisposed to the performance of its duty, but rather because it did not wish to turn that duty over to an irresponsible body. The committee regard with the utmost satisfaction the result of this debate, and await with anxiety the fulfilment of the pledges given by the Government. With the view of concentrating the objections, and exposing the anomalies of the present system into one form, the committee offered a prize of £50 for an essay which should deal with the whole subject; and they have much pleasure in reporting that sixteen essays have been received. As these are now in the hands of the adjudicators, it is not desirable to say anything further at present. The preparation and dissemination of useful information on this great question is one of the principal labours devolving upon the committee; and for this purpose liberal money contributions are indispensable. Up to the present time about £250 in donations have been received or promised from different Chambers, in sums varying from £2 to £50; but a much larger sum will be necessary to enable the committee to prosecute their work with vigour and success; and it is to be hoped that landholders and householders, as well as tenant farmers and occupiers, will see how interested they are in aiding and supporting this important movement."

On the motion of Sir M. LOPES, M.P., seconded by Mr. T. WILLSON, this Report was adopted.

Mr. T. DUCKHAM moved the following amendment of Rule 3, postponed from the last annual meeting:—"Local Chambers subscribing in advance the sum of Five Pounds per annum, to the funds of the Central Chamber, to have the power of sending a Deputed Member to the Meetings of the Council, Two Members for Eight Pounds, and an additional Member for every Two Pounds subscribed—such Members to be called 'Deputed Members of the Council.'" He contended that it was very desirable to increase the income of the Central Chamber, and that, considering the great importance of the objects in view, it was but reasonable that the subscription of £5, which was the amount fixed when the Chamber was in its infancy, should now be raised to £5.

Captain CRAIGIE having seconded the resolution,

Mr. ARKELL opposed it, urging that an increase in the amount of the subscription of the Local Chambers would not necessarily augment the aggregate received, and that many of the Chambers being small market ones, could not fairly be expected to contribute £5 per annum; while, on the other hand, many of the larger ones might easily subscribe £10 or £15.

The motion was afterwards opposed by Mr. T. CHANDLER and Sir G. JENKINSON, while the Chairman recommended its postponement, and it was ultimately withdrawn in deference to the general feeling of the meeting.

The CHAIRMAN announced that the subjects appointed for discussion in the ensuing year were as follows:—In February, "The Best Means of providing for the Future Maintenance of Turnpikes and Highways" and "The Present System of collecting Agricultural Statistics"; in March, "The Best Mode of providing Means for the Extension and Maintenance of the Education of the Industrial Classes"; in April, "The Causes now in Operation which discourage the Application of Capital to Agriculture"; in May, "Local Taxation," the precise terms of the subject to be settled on a future occasion. The June meeting of the Council was fixed for the 14th, a change being made in consequence of the first Tuesday in that month falling in Whitsun week.

Mr. ARKELL called attention to the fact that the conserrators of the Thames are going to apply for extraordinary powers as regards the management of that river from its source to London, remarking that the question was not a mere local one, commissions having been appointed to inquire into the state of other rivers,

The CHAIRMAN recommended Mr. Arkell to lay the subject before the Council; and, at the same time, expressed a hope that local chambers would in future not only discuss the topics originated by the Council, but do so at the proper time.

On the motion of Mr. T. WILLSON, a vote of thanks was

given to the Chairman for the manner with which he had performed the duties of the office of President during the past year.

The CHAIRMAN having briefly replied, the meeting separated.

CALENDAR OF AGRICULTURE.

This month is the stormiest period of the year, in continued frosts and deep snows in northern latitudes, and in heavy rains and furious winds under more benign climates. The ploughing of stubbles of clays and loams for fallows of wheat and root crops will be finished early in the month, and grass leys ploughed for Lent crops, always preferring the clay lands, to have the benefit of exposure to effect the pulverisation of the soil. This month suits very well for this purpose, and does not, by a very long exposure of the land in a ploughed state, reduce it into a hard, battered condition. The ploughing of all lands, stubbles, and leys, for fallows and crops is very advantageously performed during this month.

During the frost and snow of northern localities, the farmer's attention will be directed to carting operations of every kind—of stones to drains and roads, fuel to all house-holders on the farms, and of earths and lime for the purpose of compost manures. Deliver grains to the merchant, if any be sold, and perform all work of carting that may occur.

On lands that have been missed in autumn, sow wheat of the Lammas or spring varieties where the latter is used; the former may be later in harvest, but will be an equal crop.

In fresh weather continue the cutting of copes and underwoods, the cutting and plashing of hedges, the scouring of ditches and road sides; and clear water courses. Collect to be mixed well all earthy and vegetable matters, to be converted into a compost manure of great value; cut field drains to half the depth, to be finished in summer.

Plant trees of all kinds in clumps; single standards in underwoods, and along with new hedges. In all cases select healthy and vigorous stems of some years in growth.

Flood watered meadows, and lay dung occasionally.

The live-stock on the farm of every kind will demand the most constant attention of the farmer, if he would rear the animals to profit, and derive advantage from his labours. Never forgetting the great effects of minute care in increasing the produce of a farm, supply to the cattle in the yards, and to the horses fresh straw daily from the frequent thrashings of grain by machinery, or the constant use of the flail. Spread all litter evenly and thinly over the yards into level surface, and remove the straw cribs frequently, in order to prevent the dry position underneath remaining in a different quantity of dung from the surrounding mixtures. Give turnips or other roots early in the morning, that be cattle may eat during the day-light, and be seen when choked or swollen. The quantity given be the utmost that can be consumed by fattening animals without waste, and to store animals

about half that allowance. Turnips are best in quality when drawn from the field daily for use; but the risk of heavy snows covering the crop, and heavy rains rendering the access inconvenient, obliges to have a month's consumption in store at the homestead to supply the constant demand. A storing beyond three or four weeks lessens the quality of bulbs and tubers. A few young store pigs are very useful to roam in the cattle yards, and pick up any shells of or remnants of roots that may fall from the cribs, and to move and turn over with their snouts the straw and dung, in search of pickles of grain, and thus mix the various articles of the contents of the yards. The animals pass from yard to yard, and through a hole cut in the under bar of the gate except one.

The milch cows will now begin to drop calves; feed the dam with succulent food, with steamed roots, and chaffs. Juicy food is most essential to the secretion of milk. Suckle calves for any special rearing of animals; and feed others from the pail: but for any purpose suckling will be preferred, as no substance yet known can equal nature's milk from the mother, transferred from the udder into the stomach without exposure or evaporation. The cows may be divided into a suckling and a milking lot, to rear animals, and to produce cream, butter, and cheese. Have the calf pens divided into single apartments of about four feet by eight feet, opening into the cow shed from the end or from behind, if the width of the shed admits. The apartments are boarded in the floors, pierced with augur-holes to remove moisture, with a box or two in the corners to hold chalk or rock salt, to be licked by the animals, which are fed thrice daily.

The sheep in the fields require fresh turnip daily pulled from the ground, rooted but not topped, and carried to a stubble or ley ground, or confined by hurdles on the growing crop, and should have fresh ground every two or three days, or be confined in folds, or cleaned, and fed with sliced turnips placed in troughs. This last method is chiefly for fattening flocks. Early lambs will be dropped in some places. Juicy food must be largely allowed to the ewes, and a warm shelter in covered sheds, with an open yard.

Feed bacon hogs twice a-day with steamed roots, as steamed potatoes mashed and mixed with meals and bran. The food of brood sows may be thinner and more washy. Store pigs may have the roots in a raw state, and one feed of cooked food daily. Bacon hogs must be finished for the market by a month's feeding with hard corns, as oats and beans, to produce firmness and whiteness in the flesh. Barleymeal is the favoured food for pigs in a prepared condition.

The poultry must not be neglected. Feed with

light grains and steamed potatoes, with meals, and given in troughs, placed under a shelter sheet. Poultry houses should be heated underneath the boarded floor by pipes of hot water from the boiler house. By this means the laying of eggs and hatching of chickens will be continued throughout the year.

The foremost fattening bullocks and the early bacon hogs will come into market this month, and will command a higher value beyond later

articles. This circumstance should stimulate the forward provision for the market of the early produce.

Work-horses are best maintained on dry food, as oats and beans, chaffs, and dried herbage. But one meal daily in the evening after work may be useful, of steamed potatoes, boiled barley, with other roots and grains. The horse is a dry feeder, and warm meats may open the skin to colds, from the great exposure of the animal.

CALENDAR OF GARDENING.

KITCHEN GARDEN.

The directions of this month are necessarily few, as the weather is the stormiest of the year, in heavy cold rains in the southern parts, and in the northern with long-standing, iron-bound frosts overlaid by deep snows that cover every surface under a canopy of the severest cold; consequently, with a glorious uncertainty of weather, it is impossible to do more than suggest. At all events, they who desire to have lettuces, radishes, and salads early must be possessed of frames and lights. We do not allude to forcing, but simply to protection, yet this will imply some kinds of linings, either of dung, fern, or straw, laid so thick around the box and lights or brick pits, so as to exclude a frost of 20 degrees, which frequently visits us, and lasts many days. Every vegetable grown in frames ought to have air in fine intervals by day, but the sashes should be closed every night, and be covered whenever it freezes with straw-mats, the most effectual means of defence that can be constructed.

If the weather and ground be open, the green and white cos lettuce, and the brown Dutch, and also a sprinkling of short-topped radish, can be sown on a warm border: the earth should be free and open and rich, to promote a quick growth, and straw or fern should be at hand to throw over the surface during hard nights. Sow radishes twice over.

A little brown carrot seed, a drill of round spinach, and some mustard and cress, may be sown, but little good will result in general.

Peas and broad beans should be sown at least 2½ or 3 inches deep, in soil enriched in the autumn.

Earth up peas and beans if any be ready, observing to select the driest weather. Transplant cabbages from the seed beds.

If frosty, protect the frames and caniflowers under glasses; celery by a couple of boards laid ridgewise, or by straw on each side of the ridges; wheel out manure to be ready for plots, asparagus beds, &c., &c.

Dung applied to the ground in the spring is the better from being fermented in a heap, with the process still going on when placed in the land: the heat is very useful to the germination of seeds, and to the tender plants or the young growth, and the dung is in a condition for a ready amalgamation with the fresh-dug lands of the winter exposure. On the other hand, manure that is

saturated with moisture, as in the liquid pit, and consequently in a comparatively fresh condition, being applied to the ground in autumn, enjoys the winter months during which to decay in the land, amalgamate with the soil, and produce the black humified earth of mutual contact, which is both the product and source of life, and well known to be most highly beneficial to vegetation. Substances in a fresh state, with inherent or imbibed moisture, when used as a manure for the purpose of an immediate effect, tend to produce fibres, rootlets, and leaves rather than roots and fruits, which is avoided by using fresh dung in the autumn applications, and the fermented heaps in the spring operations.

Fermentation is very beneficially excited and continued by frequent waterings of the heap of dung with urinary and soapy liquids; and a proper mixture of the different matters in the heap, the wet with the dry, and the half-rotted with the wholly-decomposed, must be effected by turning over the heap with a fork, and with a minute attention to shake out the clods or lumps. Place in the inside the former—the whole mass in a new position of mixed matters, with a light weight. Two turnings of the heap may be required to make the changes that provoke fermentation with the new conditions and capacities of bodies. Nearly the whole value of manures rests on this result being obtained in the proper state and quantity.

FRUIT DEPARTMENT.

Prune very little unless the buds swell materially. Lay manure around the roots of raspberries, gooseberries, and currants, which very largely hastens and improves the spring growth, and increases the quantity of fruit. Place dung around the roots of fruit-trees and espaliers to produce the same results, which will be improved by placing a thin grass turf or a thin layer of soil over the animal dung that is used as mulch.

In fresh weather during the month plant trees of all sorts in clumps—standards, fruits, and berry-bearing bushes. Plant each kind in a separate connection, to preserve the generic affection which is seen to prevail in the vegetable world. Shake snow from off evergreens to save the foliage from scalding.

FLOWER GARDEN.

Little can be done in this department at this season of the year. Sow seeds in pans, mark

each, and place them in a frame. Perennials are mostly all to be propagated from the roots by divisions, slips, and cuttings, which may be

planted in the open weather of the month, along with all hardy and semi-hardy flowers of strong stems and fibrous roots.

AGRICULTURAL REPORTS.

GENERAL AGRICULTURAL REPORT FOR DECEMBER.

During the past month the wheat trade has continued in an extremely depressed and inactive state. The receipts of foreign produce have been very heavy, and altogether in excess of the calculations made at the opening of the season, while, as we write, there is a further considerable quantity of produce on passage from all quarters. Millers have, therefore, operated with great caution, as it became evident that they would be easily able to supply their wants, from time to time, if prices did not further recede, and events have fully justified their course of action. As a necessary consequence of these retail sales, the larger portion of the arrivals have been warehoused, and the demands for granary accommodation have been very great, so much so that at one time no little difficulty was found in obtaining storage room. We believe, however, that there is now full provision for all probable demands. It may be observed that the accumulation of produce, though large, comprises little of superior character, as the arrivals of Baltic and Danish wheats have not been extensive. A great proportion of the wheat in granary consists of Russian and American qualities, which have been much depressed throughout the month, though somewhat firmer in value towards the close; whereas there has been little disposition shown to accept lower prices for fine Baltic descriptions. Prices are not now likely to recede much lower, as any further reduction would again bring the continent into the market. Already several cargoes have been taken for near continental ports, the result being a slight reaction in values, which, however, has also prevented further operations on continental account. The general aspect of the market is such as to induce speculators to venture large purchases for holding, but there is an evident feeling that prices have now seen their lowest point, and as this opinion becomes more prevalent we may anticipate a return of animation, millers being unusually bare of stocks. The quantity of grain on hand, however, is too great to allow of any considerable advance in prices, and we therefore look for a steady upward movement, rather than for an excited demand.

The tendency of prices, both on the continent and in America, has been downwards, but the quotations current on this side have been too high to allow of further extensive shipments. The closing of the navigation for the winter has also had the effect of curtailing operations for the market; but the quantity of surplus produce still on hand in the south of Europe and in America is very large, and continues to make its appearance at the ports of shipment. It is expected that shipments will be resumed as soon as the navigation reopens.

The spring corn trade has ruled extremely dull throughout the month. The mild character of the past season, and the abundant supplies of maize on offer have tended to curtail the demand for feeding stuffs, and prices have accordingly been influenced in a downward direction. At one period of the month oats were extremely depressed, but a better feeling has since prevailed. Beans and peas are 3s. to 4s. per qr. cheaper than when we last wrote. Inferior and grinding barleys are also lower in price, but fine malting descriptions have maintained late rates.

Large forced sales of potatoes have continued to be made. The receipts at the metropolitan markets have been considerably in excess of the demand, and very low prices have been submitted to. The imports of foreign produce, however, have not been very extensive.

There has been a firm feeling in the hop market. With a decidedly short home crop, and disappointing importations, the trade has ruled more active, and a heavy advance has taken place in the quotations. It was anticipated that the arrivals of American hops would be very heavy; but up to this time the expectation has not been fulfilled.

The metropolitan hay markets have been fairly supplied with hay and straw, but the trade has ruled dull throughout the month, and prices are lower on the average.

Wool has been firm, although the transactions have not been very extensive. All qualities have met a fair demand, but choice lustrous and fine descriptions have been in steady request. It is believed that the improvement in the yarn trade will be maintained, and that the demand for wool will be more active in consequence.

REVIEW OF THE CATTLE TRADE DURING THE PAST MONTH.

The month of December is, without exception, the most eventful month of the year, so far as the cattle trade is concerned. Judging from the appearance of the stock exhibited on the "Great Day," the time-honoured custom of producing fat cattle for Christmas consumption has by no means deteriorated. The supply both as regards number and condition was very fine; but, at the same time, we do not think that it in any way exceeded expectations, as the necessary adjuncts for bringing stock to perfection have been liberally supplied throughout the season. On the whole, however, the show was a decided success. During the month the receipts of beasts have been on a full average scale, and a heavy increase has been noticed in the actual weight of meat. At the earlier part of the month there was a healthy demand, especially for prime stock, and the best breeds realised 5s. 8d. to 5s. 10d. per 8lbs. So soon, however, as the wants incidental to Christmas time had been met, the trade assumed quite a nominal character, and the best Soots barely realised 5s. 8d., the more general quotation being 5s. 6d. per 8lbs.

As regards sheep the supply has not been extensive, but some good serviceable stock has been exhibited. Prime breeds have been in healthy request at full prices, realising as much as 6s. per 8lbs.; but inferior qualities have been difficult to move. As in the case of beasts the demand flagged with the satiating of Christmas requirements.

Calves have changed hands quietly, but full prices have been realised. A moderate supply has been offered.

Pigs have been dull, but steady in value.

A satisfactory feature has been the cessation of the foot-and-mouth disease, owing to the cold weather; and it is to be hoped that measures will be adopted to prevent a fresh outbreak with the advent of milder weather.

Until very recently cattle have been enabled to obtain a fair feed in the pastures; but the severe frost has since effectually checked the growth of vegetation, and the demand for feeding stuffs has, in consequence, improved.

The imports of foreign stock into London have been as under:

					Head.
Beasts	5,896
Sheep	34,130
Calves	1,670
Pigs	3,119
Total	44,815
Same time in	1868	17,231
"	1867	38,336
"	1866	34,658
"	1865	66,721
"	1864	41,712
"	1863	34,435
"	1862	25,435
"	1861	21,904
"	1860	20,795
"	1859	17,430

The total supplies exhibited in the Metropolitan Cattle Market have been as follows:

	Head.
Beasts	25,689
Sheep	24,170
Calves	1,946
Pigs	680
Total	122,485

COMPARISON OF SUPPLIES.

	Beasts.	Sheep.	Calves.	Pigs.
Dec. 1868	17,770	81,780	935	1,070
1867	21,910	92,490	943	1,880
1866	20,750	71,390	1,053	1,950
1865	31,720	128,170	2,823	2,930
1864	23,780	78,410	1,441	2,700
1863	29,302	88,470	1,150	2,680
1862	25,810	85,621	1,354	3,082
1861	24,840	84,630	701	2,950
1860	24,540	82,340	1,577	2,445
1859	24,484	78,980	1,171	2,187
1858	20,523	74,275	1,472	2,450
1857	19,830	67,132	1,209	1,915
1856	23,995	73,200	1,525	2,880
1855	22,412	90,030	1,876	3,184
1854	20,219	88,880	1,573	2,746

The arrivals from our own grazing districts, as well as from Scotland and Ireland, thus compare with the three previous years:

	Dec. 1869.	Dec. 1868.	Dec. 1867.	Dec. 1866.
From—				
Lincolnshire, Leicestershire, & Northamptonshire	7,620	7,845	9,700	9,550
Norfolk, Suffolk, Essex, and Cambridgeshire	1,900	550	2,000	650
Other parts of England	2,480	2,330	2,500	2,700
Scotland	1,954	2,190	1,710	1,560
Ireland	2,990	1,292	1,042	2,670

Beasts have sold at from 3s. 4d. to 5s. 10d., sheep at from 3s. 6d. to 6s., calves 4s. 2d. to 6s., and pigs at from 4s. 4d. to 6s. 4d. per 8lbs., to sink the offal.

COMPARISON OF PRICES.

	Dec., 1868.	Dec., 1867.
	s. d. s. d.	s. d. s. d.
Beef from	3 2 to 5 8	3 4 to 5 2
Mutton	3 0 to 5 6	3 4 to 5 0
Veal	3 8 to 5 10	4 4 to 5 4
Pork	3 6 to 4 8	3 2 to 4 2
	Dec., 1866.	Dec., 1865.
	s. d. s. d.	s. d. s. d.
Beef from	3 4 to 5 6	3 2 to 5 6
Mutton	3 8 to 6 4	3 8 to 6 8
Veal	4 2 to 5 10	4 0 to 5 0
Pork	3 6 to 4 6	4 0 to 5 4

About an average supply of meat has been offered in the dead-meat markets. With a rather quiet trade, prices have ruled as follows: Beef from 3s. 4d. to 5s. 2d., mutton 3s. 4d. to 5s., veal 4s. 10d. to 5s. 4d., and pork 4s. 4d. to 5s. 8d. per 8lbs., by the carcase.

AGRICULTURAL INTELLIGENCE,
FAIRS, &c.

DONCASTER FAT CATTLE MARKET was well supplied, and at which there was a good attendance. Some prime useful, well-fed bullocks and heifers were on offer, and a good business was done, notwithstanding that most of our leading butchers had already supplied themselves from the large shows and from local breeders. All prime lots made good prices—beef averaging from 8s. 6d. to 9s. 9d. per stone. Not a large supply of sheep, but what were on offer met with ready purchasers and moved off briskly at from 8d. to 8½d. per lb. for shearing sheep, and 7½d. to 8d. per lb. for ewe mutton.

MARKINCH GREAT MARKET.—There was a capital turn-out of cattle, and the lots of fat shown were superior in quality. There was a good attendance of dealers, and a large amount of business was transacted. The top fat sold at from 9s. 3d. to 9s. 9d., and middling and inferior at from 8s. to 8s.

6d. per stone. Among the lots of fat animals disposed of, the following may be mentioned: A prime lot of three stots a £30 10s. a-head, a superior got lot of four at £22 10s., a capital lot of six at £23, three at £23, two queys at £15, two queys and a cow at £18 a-head. Farrow cows sold at from £12 to £14 a-head, and milch cows at from £12 to £22.

MUIR OF ORD FAT STOCK MARKET.—Although the number of animals shown was large, the demand for beasts exceeded the supply, and consequently good prices were obtained. Fat cattle sold at from 75s. to 78s. per cwt. Calves were in great request, and the long prices required by sellers were exceeded to by purchasers. A few lots of sheep were on the ground, for which good prices were also obtained.

NEWMARKET FAIR.—The prices of sheep and store cattle advanced, but bacon remained stationary at recent rates. Fat beef from 56s. to £3 per cwt.; new milch cows from £9 to £15, according to quality; springers from £8 to £14; strippers from £6 to £11; store hoggets from 30s. to 40s.; lambs from £1 to £1 8s.; fat sheep from 35s. to 52s.

PRESTON FAIR.—With few exceptions, the beef was only of moderate quality. There was a fair supply of sheep and calves of good quality. Beef fetched from 7½d. to 8½d.; mutton from 8½d. to 9½d., and veal from 7½d. to 8½d. per lb.

WORCESTER FAIR.—The show of fat cows, oxen, &c., was greatly under that of last Christmas, but good prices were maintained, principally 7d. to 8½d. per lb., and extraordinarily prime 9d. per lb. The top price was obtained for a heifer, fed by Mr. Pratt, of High Green, viz., £39 10s. Of sheep there were very few, and for these prices ruled good. Best wether mutton fetched 8½d.; ewes, 8d. per lb. Pigs were numerously represented, the show of porkers being in excess of recent years. Prices ranged from 12s. 6d. to 14s. per score.

IRISH FAIRS.—**NEWPORT (CO. MAYO):** First-class lots of three year old heifers and bullocks were sold at prices varying from £17 to £21 each. Second-class quality sold at from £15 to £18 each, and inferiors, which were not very numerous, from £11 5s. to £15. Good springers (scarce) changed hands at from £18 to £20; milchers (top lots) went briskly at very remunerative prices, in some cases as high as £17 each. Two year old bullocks and heifers sold readily at £14 to £16 10s. each, while inferior kinds went at £11 and upwards. Yearlings were also plentiful, and brought good prices; heifers went at £6 and £7, and bullocks from £4 to £6 10s. per head; stirks from £8 each upwards; weanling calves from £2 to £4; strippers sold at from £9 to £11 each. Best pork sold at 57s. and 58s. per cwt.; stores sold from 3s. 15s.; heavy fat pigs, which were largely supplied, went from £5 10s. to £7 10s. each; bonhams, which were numerous, sold at 20s. and £1 5s. each. Best mutton may be stated at 7½d. per lb.; best fat widders, 5½s. to 6½s. each; fat ewes from 25s. to 50s. each; ewe mutton sold at 6d. to 6½d. per lb.; lambs from £1 5s. to £2. Good cart horses brought prices as high as £16 and £17, and nags went at from £8 to £11 each.—**BALLYVAUNIS:** Springers and milch cows sold at from £13 to £20 each, three year old heifers, £11 to £15 each; two year old do. £7 to £10 each, yearlings from £4 10s. to £6, three year old bullocks from £11 to £15 each, two year olds from £7 to £10 10s. each, and yearlings from £4 5s. to £5 each.—**NEWPORT:** Some very important lots were disposed of at prices averaging from £11 to £13 for store heifers and bullocks. The majority of the stock were from mountain pasture, and consequently this class met with much dulness and prices tended downwards. The sheep department was rather diminutive, prices steady and demand dull. The following might be quoted as the average prices:—Three years old heifers and bullocks from £11 10s. to £13, two year old do. £9 to £10, yearling, £7 to £8, milch cows £11 to £12; not much in request.

CARMARTHEN BUTTER MARKET, (Friday last.)—Weather very fine, frosty, and most seasonable. The supply of Butter very limited again to-day. It is supposed farmers are holding back for higher prices. Market without change to-day, varying from 120s. to 126s. per cwt. for good dairies. Cheese steady at 27s. to 30s.

GLASGOW, (Wednesday last.)—There were 2,629 cheese laid down, and 2,149 sold. Business slow, but no quotable change in price. Cheddars, 59s. to 72s.; Dunlop, 65s. to 66s. per cwt.

MR. HENRY J. MEAKIN'S SALE OF SHORTHORNS.

BY MR. STRAFFORD.

The middle of December, after all the fat shows, is not exactly the pleasantest time of year for the sale of an entire herd of Shorthorns. The stock may look fresh from the houses, well and good; but they may also look, fresh from the pastures, very poor and bad—and such was the case with Mr. Meakin's cattle. The catalogue was only attractive for a few animals of "fashionable blood;" one especially, Fidget 7th, drawing inquiries and admirers from all parts of the kingdom. A "Bates upon Knightley" also made the journey worthy; but great was the disappointment of the number to find "Charming Maid," a poor, thin cow, with good form and a stocked udder, and Fidget 7th, with a pure pedigree of Bates blood, and no appearance of a thorough-bred animal save a little style; but, such are the caprices of fashion, the former went for 170 gs., and the latter 210 gs., both to Messrs. F. Leney and Son. Mr. J. K. Fowler and Mr. Slye were keen bidders for the "Bates upon Knightley" element; but the "pure Bates" was put in at 40, to the great astonishment of the locals, who freely talked of her market value, no flesh and no udder, as £14, and then not everybody's money, even with store cattle dear and scarce. Fifty was the next bid, and away she went rapidly to 120, which Mr. Thos. Bell, formerly of Kirklington, offered; 140 came from the representative of Col. Kingscote; and "Fifty" said the auctioneer. To the no small surprise of the distinguished *Stile*, a man in a blue coat bid and rattled away at five and ten guinea bids to 306; "ten, two hundred and ten, and the glass runs," and it did run in earnest, and out too. No name being called, it was assumed that the man in the blue coat had bought her, and somebody shouted "Is it to kill?" but it turned out that she was to join that vast multitude at Watlington, the last bidder being Mr. Geo. Allen, Knightley Hall.

The other cattle scarcely call for any notice. The first four cows went only at market value; Empress, a large, useful cow, bred from a Derbyshire herd, made 35 gs. from Mr. Parr; and the preceding lot to Charming Maid, a five-year-old cow of old Berghley Park blood, and six months in calf, realized 17 gs. One of the best-looking animals, an in-calf four-year-old heifer, with two crosses of blood, made 36 gs. to Mr. Parr. Lady Geneva, of the Walnut family, with a Booth Gwynne and Bates cross, was bought for Lord Dunmore at 75 gs., and her heifer calf by Duke of Cumberland fell to Mr. J. K. Fowler for 50 gs. A poor white heifer of the Zeal tribe sold for 53 gs. to Mr. Willingham Fowler, and Mr. J. P. Foster got the best of two heifers from the Chantress family at 33 gs. Two bought-in calves from a neighbouring sale made respectively 11 gs. and 8 gs.

The first bull was sold as fat stock for £45 5s., and a pretty roan bull calf, out of Empress, went to a Derbyshire farmer for 35 gs. Mr. J. K. Fowler bought Charming Maid's white bull for 37 gs.; and the sale of some fat bullocks and heifers, at fair market value, wound up the business. The average of £37 for 38 head is no small result for a winter sale of poor stock; and the company, many of whom got fairly stuck fast in the mud, went away soon after three with that common talk of the Midland Counties that the best beast had not made the most money.

SALE OF ROYAL STOCK.—A sale of stock, the property of Her Majesty the Queen, at Prince Consort's Shaw Farm, Windsor, was held under the hammer of Messrs. Buckland & Sons. The stock consisted of 30 very fine prime Shorthorned beasts, in excellent condition, having been fed for Christmas; also 150 Down and half-bred sheep in prime condition, the feeding of which reflected great credit on Mr. Tait, the royal bailiff. There was a large attendance of buyers, and the prices realized exceeded the average amount of the sales at the Royal Flemish Farm, on the 8th of the present month. The sale realized £1,200. The highest price of the beasts was £45 10s., and the lowest £31 15s.; the highest price of the sheep 70s., and the lowest 56s. The average of the beasts was £30 6s., and the sheep 40s. The sale altogether proved exceedingly satisfactory.

LORD DURHAM'S FAT STOCK SALE.—The annual sale of fat cattle at Bowes' House Farm, Lambton, was held last month, by Mr. Thomas Wetherell. The proceeds of the sale amounted to £4,834 8s. 25 half-bred cattle, average £31 10s. 6d.; 16 polled half-bred cattle, £38 10s.; 8 Shorthorns, £33 13s. 9d.; 25 Galloway heifers, £28 7s. 7d.; 7 West Highland heifers, £19 4s. 3d.; 3 Shorthorn cows, £28 5s.; 2 Shorthorn bulls, £30 10s.; 10 lots of half-bred Cheviot wethers, £3 2s. 7d.; 11 lots half-bred Cheviot gimmers, £3 1s.; 7 lots half-bred Southdown wethers, £3 8s. 7d.; 8 lots half-bred Southdown gimmers, £3 1s. 8d.; 5 lots Cheviot wethers, £3 5s. 3d.; 18 lots half-bred Cheviot ewes, £3 2s. 4d.; 22 lots Cheviot ewes, £3 5s. 3d.

SALE OF FAT STOCK AT BLAGDON.—The prime beef and mutton, fed on the Milkhope Home Farm at Blagdon, the country seat of Sir Matthew White Ridley, Bart., was sold. The prices were exceedingly good. The wethers averaged £3 4s. 4d., ewes £2 18s. 0d., Shorthorn bullocks £33 3s. 6d., Shorthorn heifers £34 9s. 6d., polled Galloway cattle £23 11s. 3d. The prices of the half-bred wethers ranged from 58s. to 72s. each, the ewes from 55s. to 60s., Shorthorn bullocks from £27 10s. to £44, Shorthorn heifers from £26 5s. to £50, and polled Galloway cattle from £19 to £36.

HOP MARKET.

BOROUGH, MONDAY, Dec. 27.—Our market continues exceedingly firm, with very little doing, as usual at this period of the season; but in face of the small stock of new home-growths now remaining, there is not the slightest disposition to press sales. The falling-off of arrivals from the continent, and the decreasing imports from New York impart strength to quotations and confidence to holders, giving promise of a better trade after the holidays. Advices from Bavaria and Bohemia remain without change, the market being reported steady. The Belgian markets continue weak. New York letters to the 12th inst. indicate no change in the market, which continues quiet, but firm.

Mid and East Kent	£7 0	£9 15	£12 12
Wealds	6 0	7 0	7 15
Sussex	5 12	6 10	7 0
Bavarians	7 0	9 0	11 0

POTATO MARKETS.

SOUTHWARK WATERSIDE.

LONDON, FRIDAY, Dec. 24.—Trade dull, with no alteration in prices.

Yorkshire Regents	70s. to 100s.
Lincolnshire do.	60s. to 85s.
Kent and Essex do.	60s. to 80s.
Dunbar and East Lothian do.	70s. to 100s.
Perth, Forfar, and Fife do.	70s. to 80s.
French and Belgian whites	55s. to 65s.

BOROUGH AND SPITALFIELDS.

LONDON, MONDAY, Dec. 27.—These markets have been fairly supplied with potatoes. Owing to the holidays the trade has been quite of a nominal character. The import into London last week consisted of 517 bags 1,521 packages from Antwerp, 118 sacks Dunkirk, 10 bags Dordt, and 10 bags Rotterdam.

English Shaws	70s. to 80s. per ton.
" Regents	70s. to 100s. "
" Rocks	65s. to 70s. "
Scotch Regents	75s. to 100s. "
French	60s. to 70s. "

COUNTRY POTATO MARKETS, (Friday last).—**DONCASTER:** Our market was poorly supplied with potatoes this morning; holders stood out for high prices, but these are not obtained. Regents continue to make from 9s. to 10s., and rocks from 6s. 6d. to 7s. 6d. per load.—**MALTON:** The potato trade was most retail, at 6d. to 8d. per stone; wholesale prices 7s. 6d. to 8s. per tab. Trade still.—**OTLEY:** Potatoes 8s. per load.—**YORK:** The prices of round potatoes, of which there was an average supply, were from 6s. to 7s. per tab of 280lbs. wholesale, and 5d. per 14lbs. retail.

REVIEW OF THE CORN TRADE DURING THE PAST MONTH.

The close of the year 1869 has been in character with the fluctuations which have marked all its seasons. Beginning with a smart frost, December soon gave place to extensive and damaging floods, especially affecting the Northern, Eastern, Midland, and Western counties; and, though frost again set in as Christmas came, we have yet to learn the extent of injury done to the country flooded. The property lost cannot fail to be immense from the overflow of rivers, and much injury must necessarily accrue to the health and well-being of those whose domiciles have been entered. Many fields will have to be resown, for thousands of acres have only exhibited an expanse of water; and where farmers incur the risk of leaving matters to right themselves, there is so much less prospect of a crop. Notwithstanding the perpetual excessive imports from abroad, prices were previously so much reduced that the turn of late has been upwards, and from the lowest point prices have risen during the month about 2s. per qr. This, though no material help to farmers, seems to indicate that the greatest period of depression has already passed, and should they continue as close-handed with regard to arrivals as they have been of late, in sending to London, the year will probably open with somewhat brighter prospects. Much indeed is yet coming from the Mediterranean and California; but, with the present frost, we may reckon with certainty that the Black Sea, the Baltic, and North America will do but little in the way of export. It is very remarkable, after a deficient crop, that our prices this year should have sunk so much below the rates of 1868, a year of unmistakable abundance; but as stocks in the country diminish, and confidence increases, we may yet see a moderate advance before next harvest, especially as there are general complaints abroad of the present lowness of prices. In Germany, France, Holland, Hungary, and Russia but little reduction has lately been noted; though the accumulation of stores at Odessa amounts to about 700,000 qrs., and at New York to 500,000 qrs. Most of the former will probably find its way here; but not till the frost has broken up in spring can either of these ports be available to any extent. The following prices were recently quoted at the several places named: White wheat, at Paris, 51s., red to 45s. 6d.; best wheat, at Bordeaux, 46s.; red qualities, in Belgium, 46s. to 47s.; white Zealand, at Rotterdam, 56s.; fine qualities, at Porrentruy (Switzerland) 47s.; at Romanshorn, 51s.; new red, at Hambro', 43s. 6d.; best new high mixed, at Danzig, 45s. free on board; red, at Stettin, 42s.; at Rostock, 42s.; choice heavy red, at Pesth, in Hungary, 40s. 6d., inferior 35s.; Saide wheat, at Alexandria, 37s.; red, in the Italian States, 42s. to 46s. per qr.; at Vienna, 43s.; No. 2 spring red, at New York, 36s. 5d. per 480 lbs.; winter and amber qualities 39s.; white, at San Francisco, including cost and freight to Liverpool, 48s. per 500 lbs; wheat, at Adelaide, 5s. 6d. per bushel.

The first Monday, in Mark Lane, commenced on a short supply of English wheat, and a very heavy arrival of foreign, most of which was from various Russian ports. The show of fresh samples on the Essex and Kentish stands during the morning was very limited. The demand for really fine white parcels was improved, and this enabled factors to obtain an advance of 1s. per qr., but inferior sorts were passed over. The extraordinary arrival

from Russia made sales of this sort difficult, and most was ordered to granary, but American, from improved advices, obtained an improvement of 1s. per qr. over the previous Monday's quotations. With limited arrivals of floating cargoes, these were more readily placed at fully as much money. The wheat trade in the country this week showed diversity of opinion. From the better tone at the close of the previous week, several places looked for a 2s. advance, but only a few were able to report it. Others, not so sanguine, noted a rise of 1s., with but a limited trade. Liverpool gave way 1d. per cental on Tuesday, and was dull on Friday. Edinburgh noted a decline of 1s., and Glasgow nearly as much. Foreign qualities at Dublin were dull; but fair-conditioned of home growth, not being plentiful, were fully as dear, and in request.

The second Monday noted a moderate arrival of home grown qualities, and still plenty from abroad; but not so much as the previous week by 25,000 qrs. The morning's show of samples from the near counties was unusually limited, yet millers hung back refusing to buy without some concession on former prices, which in several instances was submitted to, and low rough qualities hung on hand. The large recent arrivals from Russia and America was against the values of these sorts, and they were cheaper on board ship to the extent of 1s. per qr., some holders preferring to make this sacrifice rather than land, especially with such difficulty in procuring good storage. Floating cargoes were fully in sympathy with the general state of the market, and importers were willing to accept 1s. to 2s. per qr. less money. Again a reluctance to accept less money was shown at many country places, as at Boston, Birmingham, Leeds, Oakham, and Stockton, where no concessions were made; but 1s. less was accepted at Salford, Sleaford, Spalding, and Melton Mowbray; while Gainsboro', Lynn, Market-Rasen, Hull, Rotherham, Wolverhampton, and Gloucester were down 1s. to 2s.; but Ipswich, generally forward in rising, noted a reduction of 2s. to 3s. per qr. Edinburgh and Glasgow gave way 1s., and the tendency was downwards at Dublin.

The third Monday brought a small English supply, and there was a very marked falling off in the foreign arrivals, which sank to 13,000 qrs. Again farmers seemed determined to send very scanty supplies to market, there being scarcely anything exhibited from Kent and Essex, and that mostly inferior and in poor condition. This altered state of things influenced millers to be less particular in their purchases, and parcels such as would have been left on the previous week were readily placed at fully as much money, the best being so scarce as to command a little more money. The entire foreign trade also had a more cheerful aspect, while the late depression in American and Russian sorts causing more demand, they recovered value to the extent of 1s. per qr. Cargoes afloat also had less of the previous week's depression. This better report had its influence in the country. Notwithstanding the fact that it was Christmas-week, most places noted more cheerfulness and greater freedom in sales. Several were up 1s., as Boston, Leeds, Manchester, and Newark, and some were 1s. to 2s. dearer, as Sleaford, Louth, and Barnaley. Liverpool noted an improvement of 1d. per cental on the Tuesday's market: Both Edinburgh and Glasgow found a better demand at

rather more money, and the Irish markets were generally firm.

On the fourth Monday there were very small supplies of home-growth, with a fair quantity from abroad. The number of samples exhibited on the Kentish and Essex stands was less than at any previous period since harvest; and this enabled factors, on a very small holiday market, to obtain 1s. advance over the quotations of the previous Monday. The foreign trade, though strictly retail, and in character with the season, was also very firm, and a few sales were made at improved rates. Floating cargoes also slightly revived from the late depression.

The Imports into London for the four weeks were 16,071 qrs. English, 131,066 qrs. foreign, against 23,874 qrs. English, 43,683 qrs. foreign for the same period in 1868. The Imports into the United Kingdom for the four weeks to December 18th were 4,064,205 cwts. Wheat, 521,587 cwts. Flour, against 2,611,285 cwts. Wheat, 339,762 cwts. Flour for the same period in 1868.

The General Averages commenced at 45s. 6d., and closed at 43s. 10d.; those of London began at 45s. 1d., and ended at 45s. 5d. per qr.

The Exports from London in the four weeks were 610 qrs. Wheat, 435 cwts. Flour.

The Flour trade for the most part has been steady. A reduction of 1s. per sack on Norfolk was noted on the second Monday; but since then, with fair arrivals, the tendency has been rather upwards, Norfolk closing at 30s. per sack, and town-made, which has not varied, at 43s. as the top price. In foreign, business has been extremely dull; but rates have kept at about the previous range. The Imports into London for the four weeks were 93,066 sacks country sorts, 7,404 sacks 27,595 barrels foreign, against 86,455 sacks country, 3,812 sacks 27,186 barrels foreign for the same period in 1868.

With but limited arrivals of Maize, the trade has been rather quiet, and prices have kept at about the previous range.

New Beans and hog Peas have of late, by reduced prices, come into competition.

With moderate arrivals of British barley, and increased supplies from abroad, prices have very little altered. The best malting qualities have always been in favour, and being scarce, have commanded fully the previous quotations; but medium sorts have for the most part ruled dull, and grinding still more so; maize and oats being comparatively cheaper. The imports for four weeks were, in British qualities, 12,687 qrs.; in foreign, 45,734 qrs.; against 14,568 qrs. British, 76,900 qrs. foreign, in 1868.

The malt trade has been dull, brewers complaining of a diminished demand, in consequence of so many being out of employment. Prices, therefore, have given way 1s. per qr.; and there seems no prospect of a rally, unless more business should be doing as spring comes on.

The foreign imports of oats have continued very heavy, but, after some fluctuations, they have gained 6d. to 1s. in value during the month. On the first week we had one of the heaviest arrivals known; but as they came on the back of an unusual depression, there was then an improvement of 6d. per qr. This was lost, however, next week, and subsequently rather more than regained. Fine fresh Swedes being now procurable at 19s. per qr., and fair Russian at 18s., there seems little room for any permanent decline; and were it not for the difficulty of obtaining granary room, we think there would soon be some revival, as nothing whatever has lately come from Ireland or Scotland, and the Baltic may soon be closed by frost. The imports for four weeks were 5,671 qrs. English, 297,640 qrs. foreign; against 1,783, qrs. English, 499 qrs. Scotch, 12,198 qrs. Irish, 197,402 qrs. foreign, in 1868.

More new beans have come to market than expected, and prices have therefore given way fully 1s. per qr.; and the demand for old foreign has been slack, from their relatively high value. Still, with a bad crop, there seems but little chance of any reduction, though, quotations being reduced at Alexandria on only small supplies, Alexandrian now are worth about 38s. per qr. The imports into London for four weeks were 8,335 qrs. English, 5,927 qrs. foreign; against 2,481 qrs. English, 15,851 qrs. foreign, for the same period in 1868.

As regard peas, the English supplies have been moderate, but the foreign arrivals liberal. Middling quality boilers, as well as every description of hog-feed, have gone down 2s. per qr.; and old white foreign, for feeding purposes, have been equally reduced; but really fine white boilers, being scarce, have little altered in value, and would still command about 42s. per qr.; while inferior are only worth 36s., duns about 33s., and maples 39s. to 40s. The imports into London for four months were 2,959 qrs. English, 14,050 qrs. foreign; against 2,020 qrs. English, 17,739 qrs. foreign, in 1868.

With fair arrivals of linseed, the trade has continued nominally the same, though, to force sales, prices must have been reduced. Cakes have been moderately in demand, at unaltered rates, and still continue to fetch fair prices.

Though we have had a miserable crop of cloverseed in this country, and they are very short in France, prices, which of late were advancing, have been stopped, from the entire absence of speculation, so much money in former seasons having been lost. Rates, however, having recently risen in France, they have kept up well in London; and should only an ordinary demand be experienced, there is probability of an improvement. Trefails remain high, the crop being bad. Tares begin more to be sought at low prices, say to 35s. per qr.

*A Shorthorn Steer.
The property of The Earl of Dykeford, of Edington Hall, Wexmouth, and the best-bred
at the Wexmouth and Wexmouth Club, 1859.*

London: Published by Robinson & Taylor, 4, St. Paul's Churchyard, 1859.

PLATE III.

A PRIZE SHORTHORN STEER.

THE PROPERTY OF THE EARL OF AYLESFORD, OF PACKINGTON HALL, COVENTRY.

This steer, bred by Lord Aylesford, and calved on September 22nd, 1864, was by Viceroy (21019) out of Alexandra, by Monarch (20867); her dam Princess, by Botanist (15678)—Victoria, by Remus (15151)—a dairy cow at Packington.

Viceroy, a red-and-white bull, bred by Lord Aylesford, and calved December 8th, 1862, is by Royal Butterfly 5th (18756) out of Blushing Bride, by The Great Mogul (14651); her dam Bride, by Young Lochinvar (13164)—Lady Charlotte, by Bridegroom (11208)—Ladybird, by Lansdowne (9277)—by Sir Robert (7510)—by Charles (1815)—by Staplyton (2698)—by Rob Roy (557).

Alexandra, also bred by Lord Aylesford, a roan cow calved on January 14th, 1864, has, since the birth of this famous steer, produced another roan steer by Second Duke of Cumberland (23735), in September, 1867; a white cow calf, called Juno, by Knight of Gwynne (24278), in December, 1868; and a roan cow calf by Touchstone (20986) in December, 1869.

At the Birmingham and Midland Counties Meeting 1869, this steer took the first prize of £15, with a silver medal for the breeder, as the best Shorthorn steer of his class; an extra prize of £15 as the best Shorthorn bred and fed by the exhibitor; the President's Cup of 25 gs. as the best ox or steer of any breed or age, bred and fed by the exhibitor; £20 as the best ox or steer in the Hall, and 25 gs. as the best of all the animals in the Hall. Judges: W. Sanday, J. Thompson (Badminton), and H. W. Kearsey.

At the Smithfield Club Show in the week following this steer took the first prize of £30 as the best Shorthorn steer not exceeding three years and three months old, with a silver medal for the breeder; a silver cup value £40 as the best steer or ox in any of the classes, and a piece of plate value 100 gs. as the best beast in the show. Judges: W. Sanday, Charles Howard, and Hugh Aylmer.

At Birmingham, on first seeing Lord Aylesford's steer we wrote thus: "Nevertheless, the Birmingham judges declared that they found a superior animal in an older steer of Lord Aylesford's; and a very showy beast this is, with much grandeur, a fine quality coat, a beautiful broad back, and so on. But he is not so thoroughly

true as the other; his head is badly set on, and he is not so well covered about his shoulders. However, all the judges held to the light roan very determinedly, for they made him the best of his class, the best Shorthorn bred and fed by an exhibitor, the best of all the Shorthorns, the best of all the oxen and steers, and the best animal in the yard. At the utmost he is the best of a bad year." Writing on the opening day of the Smithfield Show we said: "A combination of circumstances has told somewhat against the inauguration of the 100 gs. premium. In the first place it was not known soon enough to ensure any especial preparation or demonstration over its award; while the uncertainty engendered by disease floating about has tended to lessen the opportunity or encouragement to 'ripen' any very crack animals. It has thus happened that the first 100 gs. winner is by no means the best beast ever seen at the Smithfield Show. Indeed, our first run through the entries, tends in every way to confirm this impression. Nevertheless, nearly all the champion animals of the year were to be found in the Agricultural Hall; Lord Aylesford's Shorthorn steer, the best of all at Birmingham; Mr. Roland Wood's Shorthorn steer, the best of all at Oakham; Sir Walter Trevelyan's Shorthorn cow, the best of all the cows and heifers at Birmingham; Mr. Outhwaite's Shorthorn ox, the best of all the Shorthorns at Leed; Mr. Bettridge's Hereford, the best of all the beasts at Abingdon, and Mr. Farthing's and Mr. Heath's oxen, the best of the Devon and Hereford breeds at Birmingham. In truth, wherever it well could be, the return-list of the Smithfield Club Show is more an echo of the Midlands' than might have been anticipated; for the Council have so contrived that in every section, save the pigs, the judges in Birmingham are represented in London. Nothing can be more impoit than this, and murmurs grew louder and louder during the morning as the awards still went the same way. Mr. Parrington, at the best managed meeting we have, makes it an indispensable condition that any judge who accepts office at the Yorkshire in August should not have acted at the Royal Society's Show in July; and the Smithfield Club must do the same by Birmingham." Again, during the week we said: "Lord Aylesford's steer, who had worn well, came out still very fresh and blooming. He is certainly an animal of much style, very

good to meet, and with a capital back; but, as we have already said of him, he is not thoroughly true—the more particularly forward. His head, not quite a nice one as he is hog-jawed, is badly set-on, and he is not well-covered about his shoulders. In fact, a much finer specimen of the Shorthorn breed was Mr. Outhwaite's ox, and there was no animal that won so easily in his class. But the judges made every allowance they could for early maturity, and so decided for the younger beast, although he would never promise to grow into so good an ox as the other."

One of the judges, as he is indefinitely put in the Club Report, says: "I think we have seen better champions than Lord Aylesford's ox;" another says, "after once looking through them we had no difficulty in putting Lord Aylesford's steer (19 cwt. 2 qrs. 23 lbs.) first in his class. This is the best steer I have seen for years, so good is he in all his points, meat so evenly laid on,

with quality, form, and hair, and fine handling, in fact, very far superior to any other beast in the yard." The third judge says: "some exception might be taken to the head and horns of Lord Aylesford's ox, but his magnificent baron of beef, with his heavy walk and immense breadth, as he met you, soon claimed for him first honours."

A judge who says "this is the best steer seen for years," would most probably not find even one of his brother judges to agree with him; while the pretty general opinion was that this was not the best beast in the yard; Mr. Outhwaite's ox, and Messrs. Martin's crossed being either of them preferred by many other judges.

The champion steer was purchased by Mr. D. Abbott, of St. John-street Road, Clerkenwell; but although a beast like this, with only a few crosses of pure blood in him, will often feed to a heavier weight than the thorough bred ones, he did not, in trade parlance, "die well."

PLATE IV.

TOPSTALL; A PRIZE HUNTER.

THE PROPERTY OF CAPTAIN BARLOW, OF HASKETON, WOODBRIDGE.

Topstall, bred by the late Mr. Corbett, of Elsham, near Brigg, Lincolnshire, in 1860, is by The Cornerstone, dam by Rocket, grandam by Old Orion, great-grandam by Old Gray—by Old Ruler.

The Cornerstone, bred from Lord Exeter's stud in 1852, is by Cothertstone, out of Valance, by Sultan, her dam Velvet, by Oiseau—Wire, sister the Whalebone, by Wacey. The Cornerstone never ran, and although he is credited with the winner of a hunter stake or two in *The Calendar* his services at the stud have been chiefly confined to country-side mares. We ourselves never saw him but once, and then under somewhat peculiar circumstances. We were acting as one of the judges at a show in the Midlands, where a short class of "stallions for getting hunters" without any other conditions was introduced. Our "Jeared brother," a very hard man over the Shires, took to a coarseish under-bred looking animal as we thought, while we ourselves, for want of a better, fancied a neat, nicely-topped horse, showing plenty of blood, but set-off by a pair of middling forelegs. We were so widely apart that a referee had to be called in, who, without a moment's hesitation, decided in favour of the big brown. This turned out to be the cock-tail British Statesman, while our choice was The Cornerstone, the sire of the prize-hunting horse of his day.

Topstall was sold by Mr. Corbett at five years old with two others for a thousand guineas the lot; and the horse went in turn by means of a London dealer to Mr. Talbot, now Master of the Ledbury Fox-hounds, but who at that time was hunting a pack of harriers on his property in South Wales. Topstall got here the character of a fine flying fencer, but he did not take kindly to the banks in Glamorganshire; while he was considered far too valuable a horse to be risked at such schooling as is required in those parts. Nevertheless, Mr. Talbot, in an exciting finish, rode Topstall into a ruined stone cottage with the roof off, and nothing for it but a standing jump out again of some five feet, when the horse cut his hocks severely by dropping too close to the wall. In 1868 Topstall, with a certificate of being one of the soundest winded horses ever examined, went back to London, and thence into Warwickshire, where Captain Barlow bought him, originally we believe, for Lord Hastings' stud. On

the break-up, however, at Donnington the then Captain took to the bay, nothing loth, and in 1869 Topstall, like Lord Byron, "found himself famous."

Topstall was first shown at Islington, where, in a class of hunters, without conditions as to weight, he took the second prize of £35, being beaten for first by Major Quentin's Placid, with Mr. Sanders' Playmate third, Mr. Drago's Gaylad, and Mr. McIntosh's Baronet highly commended, and Mr. Booth's Bannagh commended. Judges: Lord Combermere, Lord Maclefield, and Captain Percy Williams. We thus wrote of the award at the time: "Topstall has a deal of character, and was by far the most gentlemanly hunting-like horse in the class." But nearly all the judging at Islington was wrong, and a short-legged horse like Topstall did not show so well in the tan.

At the Colchester Meeting of the Essex Agricultural Society, Topstall took the All England premium of £30, beating Mr. McIntosh's St. Clare and others. Judges: Messrs. John Bennett, George Higgins, and R. B. Aylmer. We thus wrote of the award at the time: "Speaking of St. Clare, the first prize weight carrying hunter at the recent Islington show, we said that this horse 'is anything but a good specimen of a hunter; with a good forehead, and walking away well, he is slack in his back, with thin thighs, and weak in his hind legs, as looking altogether as soft as a Shorthorn.' Being the property of a resident in Essex, St. Clare was, of course, shown again at Colchester, where he was thoroughly beaten for the open prize. The horse, indeed, fairly tired and laboured round the ring like the faint-hearted animal he looks: while we are assured that his chief prowess in the field has been confined to carrying his owner a-coursing. The entry against him included three or four of Barker, the Essex dealer's horses, led off by Tom Bowline, the chief prize hunter at Chelmsford last year, but clearly a difficult horse to ride, although a fine strong goer, and admirably piloted by young Barker. With these came amongst others a weight carrier of Mr. Sexton's, Mr. Tharp's game old chamnut, and Captain Barlow's Topstall, who once away from that cockney saw-dust arena only proved his character the more, carrying Mr. George Higgins 'like oil' and of course taking the first prize.

E. H. B. 1870

Tophurst.
A prize hunter, the property of Messrs. Tophurst & Co., Tophurst, Wiltshire.
London: Published by Rogers & Telford, 24, Strand, 1870.

What after this shall we say of the judgment of the Ilington House of Lords, but what we have said already? and this is, that in some cases, such as the placing of St. Clare, of Whitby, and of the gold medal horse, The Commissioner, the awards of Lords Combermere and Macclesfield, to say nothing of Captain Williams, were as faulty and false as they well could have been."

At the Attleborough meeting of the Norfolk Agricultural Association, Topstall took the first prize of £10 in the middle-weight class, beating Mr. Mott's Michief (second prize), Mr. E. Green's Chester (highly commended), Mr. J. Savory's Tramp (highly commended), Mr. Bett's Arlescott (commended), and others. On the same day he took the Prince of Wales' cup of £20 as the best hunter on the ground, beating Mr. G. Sexton's Idle Box, the first prize horse in the heavy-weight hunter class. Judges: Messrs. Percivall (Wansford), and Hall (Ely). As we wrote at the time, "the award for the best of all was a mere matter of form, as the judges did not take two minutes in deciding in favour of Topstall, who, beyond his good looks, what with his cheerful airy manner, and pleasant style of walking away with you, should be a delightful horse to ride."

At the Ipswich Meeting of the Suffolk Agricultural Society, Topstall took the first prize of £10 in his class, and Lord Rendlesham's cup, as the best weight-carrying hunter, beating again Mr. Sexton's Idle Boy, and others. Judges: E. Green, M.P., and Captain Skipworth.

At the Manchester Meeting of the Royal Agricultural Society of England, Topstall took the first prize of £30 in a class of hunters up to not less than 14st., beating Major Gunter's Wetherby (second prize), Mr. Fyler's Tyrconnel (the reserve), and others. For the special prize of £30 for the best hunter in any of the classes Topstall was placed second, or the reserve, Sir G. Cholmley's chestnuts four-year-old, Don Juan, being pronounced

to be the best of all. Judges: Messrs. W. Smith (Melkington, N.B.), H. Thurnall (Royston), and W. Young (Beverley); but we demurred, as we wrote at the time, to this crowning honour being given to "a weak, cripply-going one like Don Juan in preference to the stylish Topstall, the very type of a modern hunter." Topstall was put in price here for His Royal Highness the Prince of Wales, but the figure was thought to be a little too high.

At the Birmingham Show in Bingley Hall, Topstall took the first prize of £30 in his class, and Mr. Westley Richards' cup as the best hunter in any of the classes, beating Major Stapylton's Sprig of Nobility, Major Quentin's Treasace, Mr. McIntosh's St. Clare, Mr. Berridge's Grafton, Mr. Wart's Thekla, Mr. Westley Richards' Shambally, Mr. W. A. Corbet's Tupaley, Mr. Westley Richards' Ashwell, and others. Judges: Messrs. J. Cookson (Neasham), and J. Topham (Welford).

Topstall is a rich dappled brown gelding, standing just under sixteen hands high. He has a good head, with a very full forehead, and a peculiar dip in the neck at about the junction of the first and second vertebrae. He is rather short in the croup, but has broad hips, and a good back; while he stands short on the leg, with his knees and hocks near the ground. Topstall is altogether a very workmanlike lengthy horse; beautifully framed, and combining power with blood. He has the further recommendation of a sweet temper, and showy, corky action, and we have seldom seen a nag that "took" so much in public.

Major Barlow has long been famous for his prize horses, but he never had such a season as in 1869, when Dalesman and Topstall fairly swept the country; indeed, if the hunting horse had only accompanied the chestnut to the All-Yorkshire show at Beverley the circle of success would have been complete.

DEODORIZERS.

BY CUTHBERT W. JOHNSON, F.R.S.

To the agriculturist; indeed to all classes, the deodorizers perform great and valuable services. Here again we derive the most important instruction from Dame Nature's Book. We had on a recent occasion to remark in this place upon the deodorizing power of earth. The dog buries his bones, the fox his prey, the cat its excreta, the North American savages the stinking skunk, and all with the same object—to keep sweet, or to render sweet, what would otherwise become offensive or pestilential. But on a far mightier scale the Almighty has provided deodorizers, which in the vegetable creation are ever purifying the atmosphere, which the animal world is as incessantly corrupting. And the vegetables by which our very existence is maintained do not confine their deodorizing services to the air we breathe, but they absorb from the soil, and assimilate those noxious products of putrefaction, which might otherwise spread disease and death around our dwellings. And then, again, the atmosphere, which supports the vegetation, which thus absorbs the gases of putrefaction, contains a rather mysterious gaseous substance, ozone, which possesses very considerable deodorizing properties. The air we breathe is, however, speedily exhausted of its ozone in close rooms and in densely populated districts; it is most copiously found in the healthy atmosphere, near the sea and in open upland localities, in lands where the inhabitants are few. A very

easy experiment evinces the different deodorizing power of different atmospheres. If two towels are washed, and then dried, the one by the fire of a close-room, the other in the open air of our garden, how very different in sweetness are found to be the two towels.

We see then that the importance of the deodorizers is not confined to the agriculturist; all classes are deeply indebted to them for their health, nay their very existence. It is true that the cultivator is, in a commercial sense, obliged to the deodorizers, since they store up for him those ammoniacal and other gases, which would otherwise escape from, and so impoverish his decomposing organic manure. It is with this object that the farmer covers his dung-heaps with earth, ploughs such manures into the soil, and spreads powdered gypsum on the floors of his stables.

These things have lately attracted the serious attention of the landowner and the citizen, and their inquiries have already done great service to many a farmer, and still greater things will yet in this way be effected.

The result, indeed, of a more copious supply of water to our towns and the construction of more complete town-drains naturally led to this. As the amount of sewage collected thus became vastly increased, the absolute necessity occurred of providing for the purifying of that great bulk of foul waters. The small quantity of sewage,

which once was hardly noticed as it flowed into an adjoining river, under a system of improved sewerage became intolerable, from the mass of impure liquid which now found its way into the stream. Its water became offensive; the fish were killed; Courts of Equity interfered; injunctions were issued; corporations were obliged to endeavour to purify the sewage before it reached the stream. Many contrivances were soon proposed, schemes appeared in all directions, and, as a general rule, a greater want of knowledge on the subject was evinced than might have been reasonably expected.

It will be instructive if we briefly examine a few of these suggested deodorizers.

The most commonly proposed of the deodorizers of sewage and other impure waters, have been charcoal, lime, and certain salts. In the application of these, very erroneous conclusions are commonly adopted, as was some years since laboriously proved by Professor Way (*Jour. Roy. Ag. Soc.*, vol. xv., p. 185). One leading error is, to conclude that the insoluble or mechanically suspended matters of such impure liquids constitute their chief fertilizing ingredients. Now, Professor Way collected at the mouth of a Croydon sewer, by straining through a flannel bag, a quantity of these matters, and after properly drying them, the following was found to be the chemical composition of 100 parts.

Organic matter	77.42
Insoluble siliceous matter	13.49
Oxide of iron	1.95
Lime	2.56
Magnesia	0.69
Phosphoric acid	2.73
Sulphuric acid	2.25
Chloride of potassium	0.63
Common salt	0.28

100.00

"I consider," added the Professor, "this material as the type of the *best* result that can be obtained by the mere mechanical filtration of sewage, and the preservation of the solid product for manure." These matters we collect in considerable quantities at Croydon, from the straining tanks, through which the town sewage passes on its way to the irrigation meads; but we are unable to sell it for more than about 2s. per load.

As Way observed, there are various forms of charcoal, lime, gypsum, clay, salts of alumina, salts of zinc, iron, and magnesia, that have been proposed as deodorizers. The use of these has been suggested sometimes separately, and in other cases two or three have been associated together. With regard to the employment of charcoal, as he continues, "great misconception exists with regard to its powers. Charcoal is known to have the power of absorbing ammonia and other gases, and that to a very considerable extent; it is therefore taken for granted that this power exists equally under all circumstances; but such is not the case. It absorbs ammonia by virtue principally of its great porosity—by a kind of surface attraction—an attraction possessed by all solids for gases, and having relation, of course, to the quantity of surface; hence charcoal, in common with all porous bodies offering in a given weight a large amount of surface, has a great absorptive power for gases. But this property is also possessed in an eminent degree by water—more especially is this the case where gases largely soluble in water are in question. When therefore we treat charcoal saturated with ammoniacal gas with water, the superior attraction of the water comes into play, and the ammonia is transferred from the charcoal to the solution. In the opposite case, when a solution of ammonia is filtered through charcoal its strength cannot be sensibly diminished."

At Croydon this property of charcoal is taken advantage

of by employing it in the ventilating traps of the sewers, where it well absorbs the gases, which would otherwise escape into the atmosphere; but it is not otherwise used at that town as a deodorizer. In some places, however, it has been employed to a limited extent in the preparation of sewage manure in two ways, which are thus described by the Professor: "In the first place it forms a filtered, through which the sewage is passed; in the second, it is mixed either with the liquid in tanks—the whole being mechanically filtered—or the sewage is first filtered through wire gauze, and the charcoal is added to the pulpy mass to deodorize it and facilitate its drying. But in whatever way it is used, it must be clearly understood that charcoal removes nothing worthy of notice from actual solution."

The next substance which we have to consider as a purifier of impure waters is lime. Way examined its action: "Sewage water filters with great difficulty, and hence it becomes necessary to find some means of causing a ready separation of the liquid and solid. Lime to a considerable extent effects this, and its use has been made the subject of several patents. The lime acts in coagulating the sewage, probably by forming an insoluble soap of lime with the grease of the liquid and by neutralizing the carbonic acid which abounds in fermented sewer water, and which holds in solution carbonate and phosphate of lime, and other salts. A precipitate is thus formed, which encloses in it the light floating organic matter which would not otherwise subside."

The lime process has long been employed on a large scale, at Leicester, where it is known as Wicksted's process; and also at Hastings, where it was introduced by Messrs. Noone. In neither place has the success it has met with been worthy of the energy and skill employed by the inventors. The Leicester process been reported upon by the Queen's commissioners appointed to inquire into the pollution of rivers, to which I shall presently refer. Messrs. Noone's system has been recently described by them (*Engineer* for 1869, p. 414.) nearly in the following words:

They employ a dredger for raising solid matters from the dredger pit, which is in communication with a large underground tank, constructed to receive the whole of the town sewage. A trunk or shoot conveys the solids from the dredger to a covered iron tank, where they are stirred and mixed by means of an agitator.

From the tank the solids pass on over a weir and under a dipping plate into a second tank, called the ammonia tank, where they are mixed with milk of lime from a lime tank, and are further stirred and amalgamated by an agitator. The ammoniacal gas liberated by the lime passes over into an earthenware condenser containing hydrochloric acid, and is there fixed.

From the ammonia tank the solid matters pass on in a semi-fluid state to an endless wire cloth, travelling nearly horizontally on rollers in a chamber. The wire cloth strains off the water from the solids, and carries them into the drying chamber, which is made with three circular troughs or channels one above another. The solids are received in a pasty state in the upper trough, and are kept travelling in it by means of revolving scrapers.

When the solids have passed round the upper trough they fall through an aperture into the second trough, where they are carried round by similar scrapers, and then fall into the lower trough, where they are treated in the same manner, and are finally delivered in a partially dried state. The chamber is heated by flues passing under each of the circular troughs from the furnace door.

The lime tank has an agitator, and the milk of lime is conveyed into the ammonia tank by a pipe.

The ammonia tank is sealed by a dipping plate at the

opening, which allows the solids to pass on to the wire cloth and prevents the escape of gases. When the hydrochloric acid in the condenser is sufficiently neutralized and saturated with ammonia, a portion of it is drawn off from the condenser to the evaporating pans, where the acid being driven off by heat, the ammonia is recovered in the form of sal ammoniac.

The works are not now in operation, the machine as erected having been found too large for the town of Hastings.

The chemical composition of the solid manure, prepared by a lime process (with probably charcoal), was examined by Way. He found in 100 parts;

Moisture	4.39
Charcoal and organic matter	36.58
Sand, &c.	9.88
Oxide of iron and alumina	1.84
Phosphate of lime...	5.51
Carbonate of lime, with a little carb. of magnesia	32.92
Sulphate of lime	8.18
Alkaline sulphates and chlorides...	0.78

100.00

When only lime is added to the sewage the amount of carbonate of lime in the manure precipitated is much larger than in the foregoing analysis. Way calculated that the excrements of each person in London are mixed with 20 gallons of water; and as when the sewage is precipitated by lime each gallon of water furnishes 80 grains of chalk, we have 600 grains of chalk as the quantity which is added to 437 grains of solid excrement; so that the manure produced would on this showing contain nearly 60 per cent. of carbonate of lime. This is a startling fact, and one, adds the Professor, well worthy of the attention of those who are advocating the process.

The Professor also analysed a manure made from London sewage by precipitated sulphate of alumina, lime, and charcoal. He found in it per cent. (*Jour. Roy. Ag. Soc.*, vol. 15., p. 161):

Moisture	36.20
Organic matter, charcoal, &c.	19.65
Sand, &c.	10.47
Oxide of iron and alumina	4.31
Phosphate of lime	2.63
Sulphate of lime	5.89
Carbonate of lime	20.35
Alkaline sulphates and muriates	0.50

100.00

In the report of "the Rivers Pollution Commissioners" they contrast the results obtained at Leicester by treating sewage by the lime process with that by Mr. Sillar's invention, this last being known as the A. B. C. process, so named from the initial letters of the principal re-agents employed, viz., alum, blood, bones, clay, and charcoal.

There are other substances, however, employed by Mr. Sillar than those I have mentioned. I find from an obliging communication from Mr. Baldwin Latham, the engineer to the Croydon Board of Health, that the following are the ingredients and proportions in the mixture used in the patent A. B. C. process:

	Parts.
Alum	600
Blood	1
Clay	1,900
Magnesia	5
Manganate of potash	10
Burnt clay	25
Common salt	10
Animal charcoal...	15
Vegetable charcoal	20
Magnesian limestone	2

As the commissioners remark in their report the purification of sewage may be conveniently considered under

two heads—1st, clarification, or the removal of suspended matters, so as to render the resulting liquid more or less clear and transparent; and, 2ndly, the removal of matters in solution. The suspended matters contained in sewage are well known to undergo rapid putrefaction, and to become very offensive, consequently their removal, either by filtration or by chemical treatment, constitutes in itself an important amelioration in sewage. But the liquid so clarified contains in solution much nitrogenous organic matter, which is prone to become putrid even mixed with a considerable volume of river water. In regard to clarification, the report informs us the experiments at Leicester scarcely establish a decided superiority for Mr. Sillar's process over the method of treatment by lime. On the first day the effluent liquids were nearly equally clear; on the second day the limed sewage was markedly superior to its rival; whilst on the third day the sewage treated by the new process was much clearer than the limed liquid. The suspended matter in 100,000lbs. of this effluent sewage was as follows:

	After Lime Process.	After Sillar's.
	lbs.	lbs.
1st day	6.00	6.12
2nd "	2.84	4.36
3rd "	6.56	2.76

Of the soluble constituents of sewage the following table gives the total solid impurity removed or added to the sewage by the lime or Sillar process. The numbers, as usual, refer to 100,000lbs. of sewage:

Lime Process.	Removed.	Added.
	lbs.	lbs.
1st day	23	—
2nd "	22	—
3rd "	11	—
Sillar's Process.		
1st day	—	6
2nd "	—	13
3rd "	—	11

The numbers show that whilst the lime process considerably reduces the amount of dissolved impurities in sewage, Sillar's process markedly augments it. The explanation is obvious: in the lime process, which is in fact an application of the late Professor Clarke's ingenious method of softening water, all the material added in solution is again precipitated in the solid form; but in Sillar's process considerable quantities of dissolved chemicals are added which are not afterwards precipitated.

The material, however, which it is of the greatest importance to remove from the dissolved constituents of sewage, is nitrogenous organic matter, because it is chiefly this kind of organic matter which enters rapidly into putrefaction, and becomes an active agent in polluting rivers. It is precisely here that both processes signally fail (although the lime is slightly superior to the new process) in accomplishing such an amount of purification as would render the sewage admissible into an open water course. The composition of the manure obtained by both processes was ascertained by careful analysis. The following results in per centage numbers were obtained. The dried mud of the two processes was composed of—

	The Sillar.	The Lime.
Mineral matters	54.772	37.413
Organic and other volatile matters	45.228	62.587
Carbon	24.994	18.865
Phosphoric acid	.496	.147
Total nitrogen	1.945	.549
Ammonia	.185	.090

It is thus evident, continues the commissioners, that in the three valuable constituents of manure, viz., in ammonia, in other forms of combined nitrogen, and in phosphoric acid, the manure obtained by the new process is

greatly superior to that resulting from the treatment with lime. Unfortunately some doubt is thrown upon the source of the increased amount of phosphoric acid present in the manure obtained by the new process, because bone-black, in (to us) unknown quantity enters into the composition of the precipitating material used by Mr. Sillar, and thus an uncertain amount of phosphoric acid is added to that which is actually derived from the sewage.

The commissioners estimate the value per ton of the two manures to be as follows:—

				£	s.	d.
From the lime process	0	13	6½
" Sillar's	1	13	0½

Such is the value of these deposits as estimated from chemical analysis; but experience has warned the manufacturer of these feeble manures that the value indicated by chemical analysis cannot be counted upon in the market. Thus, the Leicester mud is actually sold for 1s. per ton., although its indicated value is 18s. 6½d.

The commissioners (Messrs. W. Denison, E. Frankland, and J. C. Morton), at the conclusion of their valuable report, thus summarise the results of their experiments: 1. That Sillar's and the lime processes remove to a great and nearly equal extent the suspended matters contained in sewage. 2. That Sillar's process increases the amount of dissolved solid impurity in sewage, but reduces the quantity of putrescible organic matter. The

lime process reduces both the amount of dissolved solid impurity and the quantity of putrescible organic matter; the reduction of the last being about the same as that effected by Sillar's process, viz., rather more than one-half. 3. Like all chemical modes hitherto invented, both processes fail in purifying sewage to such an extent as to render it admissible into running water. It still remains a fact, that no chemical process is known which even remotely approaches irrigation in its efficiency as a purifier of sewage. 4. For the manufacture of solid manure from sewage, Sillar's process is greatly superior to the method of treatment by lime, although it fails to extract from the liquid more than a very small fraction of its valuable contents.

From the result of these laborious investigations, the reader will form a fair opinion of the action of the chief deodorizers hitherto rendered available. I have on a previous occasion enlarged upon the use of earth in composts, and in this paper I have avoided remarking upon several valuable preparations which have on a limited scale been employed, such as carbolic acid, chloride of lime, nitrous acid gas, &c., &c., since these have never been used to the large extent to which deodorizers are required in the operations of my readers. The question is of very great and increasing importance, for it relates not only to the saving of great amounts of hitherto waste than wasted fertilizing matters, but also to the increased health and duration of life of our fellow creatures.

HIGHLAND AND AGRICULTURAL SOCIETY OF SCOTLAND.

The general meeting of the Highland and Agricultural Society was held in the Society's Hall, George IV. Bridge, the Marquis of Tweeddale, K.T., president, in the chair. The following noblemen and gentlemen were proposed as office-bearers for 1870:

PRESIDENT.—Most Noble the Marquis of Tweeddale, K.T.
VICE-PRESIDENTS.—Right Hon. the Earl of Dalkeith, Right Hon. R. C. Nisbet Hamilton, Right Hon. the Earl of Selkirk, Right Hon. the Earl of Stair.

EXTRAORDINARY DIRECTORS.—Sir William Baillie, of Polkemmet, Bart.; Sir Alex. C. B. Gibson-Maitland, of Barnton, Bart., M.P.; Robert Dundas, of Arniston; Peter M'Lagan, of Pumpherston, M.P.; John Stirling, of Kippendavie; Sir William Jardine, of Applegarth, Bart.; Sir Thomas Buchan Hepburn, of Smeaton, Bart.; Robert Vane Agnew, of Barnbarroch; Patrick Dudgeon, of Cargen; Wellwood H. Maxwell, of Manches, M.P.

ORDINARY DIRECTORS.—Graham Somervell, of Sorn; Graham Binny, W.S., Edinburgh; Colonel Archibald Campbell, of Blythwood; Colonel James Dundas, of Carron Hall; Robert Elliot, Leithwood, Dunkeld; James Geddes, Orbliston, Fochabers; John Ord, of Muirhouselaw; Major John Ramey, of Barra; Robert Russell, Pitmuir, Leven; Sir James Gardiner Baird, of Saughton Hall, Bart.; Hew Crichton, S.S.C., Edinburgh; Charles Lawson, of Borthwick Hall; Alexander Mc'Donag, Granton Mains, Edinburgh; Thomas Mylne, Niddrie Mains, Liberton; Thomas Coutts Trotter, Champfleurie, Linlithgow; John Wilson, Edington Mains, Chirnside; Sir George Warrender, of Lochend, Bart.; Robert Binnie, Seton Mains, Longniddry; John Dickson, of Corstorphine; Thomas A. Hog, of Newliston; James Evan Newton, Lynbank House, Lanark; John Wilson, Professor of Agriculture, University of Edinburgh; Alexander Young, Keir Mains, Dunblane; Sir Archibald Hope, of Pinkie, Bart.; Adam Curror, The Lee, Edinburgh; Capt Maitland Dougall, of Scotsraig, R.N.; Wm. Ford, Hardengreen, Dalkeith; Andrew Mitchell, Alloa; Capt Tod, of Howden; James Seton Wightman, of Courance.

OFFICE-BEARERS.—The Right Hon. Sir William Gibson-Craig, of Riccarton, Bart., treasurer; Sir William Stirling Maxwell, of Follos, Bart., honorary secretary; Elishah

Norton Menzies, secretary; Rev. James Grant, D.C.L., D.D., chaplain; Thomas Anderson, M.B., Professor of Chemistry, University of Glasgow, chemist; Kenneth Mackenzie, C.A., auditor; John Wilson, Professor of Agriculture, University of Edinburgh, professor of agriculture; W. J. Macquorn Rankine, LL.D., Professor of Civil Engineering, University of Glasgow, consulting engineer; Alexander Slight, practical engineer; Gourlay Steell, R.S.A., animal portrait painter; William Williams, professor of veterinary surgery; William Edwin Duns, professor of cattle pathology; Thomas Duncan, clerk; John MacDiarmid, junior clerk; William Blackwood and Sons, publishers; Neill and Company, printers; Mackay, Cunningham, and Co., silversmiths; Alexander Kirkwood and Son, medallists; John Watherston and Sons, inspectors of works; William McNeill, messenger.

CHAIRMEN OF STANDING COMMITTEES.—Argyll Naval Fund, Admiral Sir William J. Hope Johnstone, K.C.C. Chemistry, Professor Anderson. Cottages, Harry Maxwell Inglis, of Logan Bank. District Shows, A. Campbell Swinton, of Kimmerghame. Finance, Anthony Murray, of Dolerie. General Shows, Alexander Kinloch, jr., of Gilmerton. Hall and Chambers, John Ord Mackenzie, of Dalphingston. Law, Graham Binny, W.S. Machinery, John Gibson, Woomat. Monthly Meetings, Sir Thomas Buchan Hepburn, Bart. Premiums for Reports on the Science and Practice of Agriculture, William S. Walker, of Bowland. Premiums for Reports on Woods and Forests, Professor Balfour. Publications, Alexander Forbes Irvine, of Drum. Veterinary Department, Andrew Gillon, of Wallhouse.

Mr. GEORGE HARVEY (Whittingham Mains) remarked on the great preponderance of Mid-Lothian farmers who had got into the list of directors. He thought they had only got one farmer on the frontier of East-Lothian, while there were five farmers from Mid-Lothian; and he wanted to know if there was any good reason to be assigned for that. The latter were all honourable men—he found no fault with them; and he hoped that they were all honourable men. These directors had privileges; they went down to the annual shows; a large hotel was taken to accommodate them; they got free beds and had free access to all that was going on. That was not a great thing; still, if it was a privilege, he thought the farmers

in East Lothian should get a share. It was not a case of "sour plums" on his part, for he had already been a member of the board of directors, when the Society was in a critical position, and he had no desire to be in it again. But holding the position he did of treasurer and convener of the East Lothian Society, he thought he was entitled to speak up on behalf of that county. He did not make a motion proposing any alteration of the list; but he thought it was a matter which he considered to be deserving of attention.

The list was accordingly agreed to.

The Duke of Buccleuch proposed that Miss Burdett Coutts be elected a lady member of the Society, and the motion was carried with acclamation.

Mr. FLETCHER N. MENZIES, the Secretary, read the following list of 89 new applications for admission to the membership, all of whom were elected.

Hamilton, The Hon. Robert Baillie, Langton, Dunee
Forrest, Sir John, of Comiston, Bart., Mid-Lothian
Alexander, James, Balmule, Dunfermline
Allan, William, Drummondrieoch, Ferintosh
Anderson, William, Rainbow Hotel, Edinburgh
Ballingal, Andrew H., W.S., Perth
Boag, Thomas Elliot, Lanton, Jedburgh
Bryan, Fred. George Daniel, factor, Drumpeller, Coatsbridge
Burgess, E. C., Dalrig, New Cumnock
Carruthers, John, Tundergarth, Lockerbie
Clephorn, Hugh, M.D., F.R.S.E., Stravithy, St. Andrews
Coghill, David, treasurer, Hutchesontown Gardens, Glasgow
Coghill, George, secretary, Hutchesontown Gardens, Glasgow
Cove, Robert, Oldcastles, Chirnside
Craig, Daniel, Barr, Sanquhar
Crosarty, William, Widewall, Orkney
Dalziel, George, Auchengruth, Sanquhar
Davidson, Gilbert, banker, Hawick
Davidson, Hugh, procurator-fiscal, Lanark
Dickson, Alexander, Hartree and Kilbucko, M.D., Professor of Botany, University of Glasgow
Drev, James, Craigenacilla, Wigtownshire
Drummond, W. P., seedsmen, 55, George Street, Edinburgh
Dugdon, Alexander, East Dalmeny, South Queensferry
Dunlop, Alexander Murray, jr., Corsock, Dalbeattie
Ferguson, John, seed and manure merchant, Sanquhar
Ferguson, William, Kinnmaddy, Mintlaw
Fletcher, Major Joseph, Kelton House, Dumfries
Gardner, John, 73, Abbotsford Place, Glasgow
Gibbons, John, cattle salesman, Liverpool
Greig, James Alexander, Terregiestown, Dumfries
Halkett, David, banker, Alyth
Haley, John, Dornoch, Crieff
Harkness, Christopher, Provost of Dumfries
Hay, Alexander, Easter Culmalundie, Perth
Hutchison, Thomas, Greenend, Liberton
Hyslop, John, Bank House, New Cumnock
Iaeh, Thomas, Gilkeracleuch, Abington
Ingram, Alexander, Challoch, Stranraer
Kennedy, William, Kirkland, Sanquhar
Kerr, Joseph, Flatts of Cargen, Dumfries
Lyon, Thomas Arthur, Foxwood, Dumfriesshire
McAdam, James Nicol, Woodfield, Banochry
McClew, John, Diavin, Portpatrick
McCulloch, David, bank agent, North Berwick
McGowan, William, Bleggie, Upper Keith
Macgregor, Donald, Royal Hotel, Edinburgh.
McHaffie, William James, Torhousemuir, Wigtown
McKean, Andrew, Airlies, Wigtown
MacLaine, Murdoch, Lochbuey, Oban
McNaughton, Daniel (McLean and Hope), Leith
Macpherson, Major Lachlan, Glentram, Kingussie
Macquene, James, Crofta, Dalbeattie
Main, George Agnew, banker, Whithorn
Marwell, John Heron, jr., Springkell, Ecclefechan
Menzies, William John, W.S., Edinburgh
Merrieks, H. J., Gunpowder Mills, Roalin
Merrieks, J. L., Gunpowder Mills, Roalin
Merrieks, William, Gunpowder Mills, Roalin
Miller, William, Niddry Main, Winchburgh
Millie, George, Kilmarnock, Cupar-Fife
Minto, John D., Kelton, Dumfries
Mundell, Walter Grieve, Inverland, Lochbroom, Dingwall

Mure, William, 12, Ainslie-place, Edinburgh
Ogilvy, Colonel, Rannagulation, Blairgowrie
Porteous, John, Whim, West Linton
Fullar, John, Lord Provost of Perth
Ralston, A. R., Warrick Hill, Kilmarnock
Robertson, Peter, Ettridgie, Kingussie
Robertson, William A., Abbotshill, Dalvey, Forres
Routledge, William, Edrig, Port William, Wigtownshire
Ryrie, Robt., 34, Park-street, Grosvenor-square, London
Scott, John, Clebrig, Lairg
Sim, Henry, Ardullie, Evanton
Sloan, John, Barnhill, Patna, Ayrshire
Small, John Lumsden, Foodie, Cupar, Fife
Stark, Robert, Kirkcaldy
Steel, Gavin, Carfin, Crossford, Lanark
Stewart, Donald, Biallid, Kingussie
Teehan, Michael, Lochside, Terregles, Dumfries
Thomas, Robert, Noranside, Forfar
Thompson, William, Ryle, Alnwick
Tod, John Wharton, W.S., 66, Queen-street, Edinburgh
Tod, Thomas M., Findaty, Kinross
Walker, Alexander, Stage-bank, Heriot, Gorebridge
Weston, Major, Golepie
Whyte, Archibald, Cotton, Alyth
Wilson, Robert, linseed crusher, Dundee
Younger, Henry J., Bilston Lodge, Loanhead.

The gentlemen in the above list were unanimously admitted.

Mr. KENNETH MACKENZIE, C.A., laid on the table the abstract of the accounts of the society for the year 1868-9. The total income for the year, including £5,980 19s. 10d. from receipts at Edinburgh Show, 1869, and £1,500 reinvested, and £767 12s. 2d. of a balance due by Royal Bank of Scotland at 30th Nov., 1868, was £12,073 13s. 1d.; and the expenditure, including £2,319 6s. 5d. as general expenses of the Edinburgh Show, was £7,322 3s. 6d.; leaving a balance of £4,851 10s. 7d., of which £4,050 has been invested on Debenture Bonds. There are medals on hand of the value of £10 6s. 6d.; arrears of subscriptions, considered recoverable, £58 10s.; and a balance in the Royal Bank of £732 14s. 1d.

Admiral Sir W. HOPE JOHNSTONE gave in the abstract of the accounts of the Argyll Naval Fund for the year 1868-9. The following was the charge: Balance in Royal Bank of Scotland at 30th Nov., 1868, £280 17s. 4d.; interest on £3,000 heritable security, £117 6s. 1d.; interest on £2,300 Debenture Bonds, £94 5s. 11d.; progressive interest on bank account, £2 0s. 10d. The expenditure consisted of allowances to five recipients to the amount of £200, and there is a balance in bank of £274 10s. 2d. He stated that there was no difference in the young officers since last year. The accounts were certified by Mr Murray, the chairman of the Finance Committee; Mr Trotter, a member of the Finance Committee; and Mr. Kenneth Mackenzie, the auditor; and he need only say that he regretted none of these young officers had got a step of promotion during the last year; because, if they had, they would have made way for some other Argyllshire youths to be brought forward and trained in such a way as that they might become good and gallant officers in the navy. In the sister service of the army, Scotland had produced many eminent officers. In the year 1809, he might call to the recollection of the meeting, this very month, the three senior general officers who commanded at the battle of Corunna were all Scotchmen—Sir John Moore, Sir David Baird, and Sir John Hope. Many other eminent men had been produced by Scotland to swell the list of general officers, of whom he might mention Abercromby and Sir Colin Campbell. In the navy Scotland had also produced many officers who fought gallantly. Admiral Duncan and Lord Cochrane were well known for their deeds of bravery many years ago; and he looked forward to the young officers receiving from this fund, having Highland blood in their veins, taking a high place in their profession.

The report was adopted.

The SECRETARY read the following report in regard to the Dumfries show, which has been arranged to take place on the 26th, 27th, 28th, and 29th July next: "The district connected with the show comprises, as on former occasions, Dumfriesshire, the Stewartry of Kirkcudbright, and Wigtownshire. The counties have all agreed to a voluntary assessment according to rental in aid of the auxiliary fund, and the town council of Dumfries have subscribed £50 towards the same object.

The premiums offered amount to about £1,500, irrespective of what may be awarded for implements and for the first prize animals at former shows of the society. The classes of stock have been for some time before the public, and the list with the premiums and regulations will be immediately published. Instead of the judging beginning at nine o'clock on Wednesday morning, it will commence at one o'clock on Tuesday, and the yard will be opened on Wednesday, Thursday, and Friday, as well as during the judging on the afternoon of Tuesday. The directors have named Mr. Maxwell of Munches, M.P., convener of the local committee. That committee will be named at the respective county meetings on the 30th of April."

The report was adopted.

The SECRETARY read the following report of the committee in regard to the proposal for holding the society's show at Perth in 1871: "A requisition was received for a show being held at Perth in 1871, for a district comprising the eastern division of Perthshire, western division of Forfarshire, Fifeshire, and Kinross-shire. The requisition was favourably entertained by the directors, who remitted to the Committee on General Shows to suggest the classes of stock for which premiums should be afterwards offered. This list was submitted to a meeting of members held at Perth, and it is for this meeting to give its formal sanction to the show being held at Perth in 1871. The last meeting there was held in 1861, and, according to the usual rotation, the show falls to be held at Perth in the year mentioned in the requisition."

It was resolved that the meeting approve of the show being held at Perth in 1871, and that the directors be empowered to make the necessary arrangements.

Mr. DUDGEON (Gargen) submitted to the meeting the report of the district competitions held during 1869. Premiums had been awarded in money to the amount of £364; beside four medium gold, 21 large silver, 151 medium silver, 25 cottage, and 180 plough medals, independent of the vote of £50 to the Edinburgh Christmas Club, and the grant of medium silver medals to the Forres and Northern, and the Northern Counties fat show clubs, making the total amount expended on this branch of the society's operations during the past year £676 14s. 6d. in above 270 districts of Scotland. The money premiums were paid and all the medals issued on the 30th December last.

Mr. DUDGEON further stated that the committee, finding that many of the larger prizes go year after year to the same individuals, have resolved, with the view of increasing competition, that there should be a greater number of premiums, and it is proposed in future that there should be in cattle ten prizes in place of six; in mares, three in place of one; in colts and fillies, twelve in place of four; in sheep, thirteen in place of five; in swine, seven in place of five; and in dairy produce, eight in place of six. Some modification in the amounts offered have been rendered necessary, but as it has enabled the directors to place a greater number of districts on the list, it is hoped the arrangements will meet with the approval of the present meeting. In the cottage and garden section it is proposed that the society should pay the whole prizes, and limit the competition to five consecutive years in each parish. The number of districts the directors suggest for 1870 are—eight for cattle at £17, and four silver medals each; three for stallions at £25 each; one for brood mares at £7, and silver medal; one for colts at £8, and two silver medals; five for sheep at £16, and five silver medals; one for swine at £7, and three silver medals; one for dairy produce at £6, and four silver medals. Another district (viz., Kilmarnock), four medium gold and eight silver medals for cheese and butter. As the committee felt itself unable to meet all the demands for money premiums, they have been as liberal as possible with the offer of silver medals, and it is a matter of much gratification to the directors to report that every application for assistance has been complied with in one shape or another. The premium book for 1870 is in course of publication, and it will be found that there are 79 districts down for no fewer than 215 medium silver medals in aid of premiums given by local societies. The meeting is aware that the plough medal is given without previous application on a certificate by a member of the Society who has attended the match, provided the report is lodged within one month of the competition, and premiums to the amount of £3, awarded by a local society or ploughing association, the name of which must

be registered with the Highland Society. Form of the report, containing the regulations, can be obtained on application to the secretary. In the department for cottages and gardens there are twenty parishes on the list, and £3 in money and four silver medals are offered to each. Besides the premiums now reported on, the Society offers the gold medal to the proprietor who shall report the improvement of the greatest number of cottages in years 1867, 1868, and 1869; and the gold medal to the proprietor who shall report the erection of the greatest number of approved cottages during the same years. The gold medal is also offered to the proprietor who shall have erected on his estate the most approved farm dwellings in reference to the proper accommodation of farm servants. There are certain conditions attached to these premiums, copies of which will be furnished on application at the Society's chambers. Before sitting down, Mr. Dudgeon stated that it was proposed to renew the grant of £50 to the Edinburgh Christmas Club; and he asked the meeting to sanction the different premiums now suggested for 1870.

The reports were approved of.

Sir WILLIAM STIRLING-MAXWELL reported as follows: The show which was held in Edinburgh in July last was one of the most satisfactory ever held under the auspices of the Society, and in a pecuniary point of view it had been successful beyond anticipation. When the Society held its meetings in Edinburgh in 1869 the surplus on the show amounted to £74 6s. 5d. On last occasion, as has already been stated, the probable surplus will not be less than £2,067. This sum might have been somewhat larger, but the directors, in consideration of the great success of the meeting, resolved to vote a silver medal to all commended implements and animals except poultry. The due for this medal was in course of being prepared, and would bear the Society's arms. As the meeting was aware, the Society is much indebted to its noble president and various other members, and the directors had requested him to move the following resolutions of thanks: 1. "That the thanks of the Society be given to the Most Noble the Marquis of Tweeddale, K.T., president of the Society, for his attendance at the Edinburgh show, and for the warm interest evinced by his lordship in promoting the objects of the meeting." 2. "That the thanks of the Society be given to his Grace the Duke of Buccleuch and Queensberry, K.G., for officiating (in the unavoidable absence of the President) as chairman at the public dinner, and for his Grace's personal exertions and support on the occasion of the Edinburgh Show." 3. "That the thanks of the Society be given to William Chambers, Esq., late Lord Provost of the city of Edinburgh, for the special interest he manifested in the success of the Edinburgh Show, for attending officially along with the magistrates on the opening day of the Show." 4. "That the thanks of the Society be given to the magistrates of the city of Edinburgh for their liberal subscription towards the Premium Fund of the Edinburgh Show, for allowing the meadows to be used for the purposes of the showyard; for the very efficient services of the police; and for the assistance rendered by the city authorities in carrying out the various arrangements of the meeting." 5. "That the thanks of the Society be given to the Commissioners of Supply for the counties of Edinburgh, Haddington, and Linlithgow, for the liberality with which the auxiliary fund of the Edinburgh Show was provided." 6. "That the thanks of the Society be given to Robert Dundas, Esq., of Ardstoun, who discharged so satisfactorily the duties of convener, and to the other members of the committee of superintendence for their zealous exertions in the duties devolving upon them at the Edinburgh Show. Sir William Stirling-Maxwell went on to say—I believe that I need not enforce the resolutions by any lengthened remarks; but I think it will be a pleasure to the members of the Society here present to congratulate our noble President on having been able to attend at our last show, and also to be present here to receive the thanks now moved to him, and to others, on whose zealous and efficient services so much of the success of the Show depended.

The report and resolution were agreed to.

The CHAIRMAN said; The next subject to be taken up is the report of the Committee on Steam Cultivation. Although we have been long in giving in the report, we have taken as much pains as we could to master the subject. The report will appear in due time in the Transactions of the Society. I must say this, that the committee were confined to a particular district to get the necessary information, and I am sorry to say

that we have not received that amount of information which would enable us to make so full a report as we could have desired. We think that much more information would be required before it could be said that steam cultivation will be as suitable for Scotland as it is for England. We must remember that in the countries where steam cultivation is general the soil is quite of a different nature from what it is in this country. In England the soil is mostly alluvial, whereas in this country the soil that has been brought down by currents of water from the hills into the low grounds is mixed with stones, and the expense of cultivating it is, I believe, so much increased in consequence of that. You have got an excellent report by Mr. Hope, Fentonbarns, on steam-ploughing; and I hope that in the course of a short time we shall be able to give you more information on this important subject than we can at present.

The SECRETARY then read the following conclusions, to which the committee had arrived on the subject:—

"1st. The committee observe that cultivation by steam-power is much more common in England than in Scotland. It cannot be said that the farmers of Scotland do not possess practical knowledge, skill, and economy in the management of the land, and yet they seem to adhere to ploughing the land with horses, which the committee, however, believe as a rule, much better done in Scotland than in England.

"2nd. The committee are of opinion that before a steam plough can be advantageously employed, the land should be thoroughly cleared of all large stones and other impediments to the free action of the plough, and that this can be most effectually done by having the land previously ploughed by horses to the depth of 14 inches, in the same manner as the committee saw done at Yester by the Marquis of Tweeddale.

"3rd. The committee are farther of opinion that where deep cultivation is desired (that is, not less than from 12 to 14 inches) the double engine system of Fowler appears to be best suited, as the action of the engine is more direct, and a much less extent of rope is required. Deep cultivation must, however, entail a great strain on the implements, and a consequently increased risk of breakage.

"4th. Where a shallow furrow (that is, not exceeding 8 inches on ordinary soil) is all that is required, the single engine and moveable anchor system of Fowler, or the roundabout system of Howard, but with Fowler's balance plough, seem well adapted. Fowler's system requiring a shorter rope and fewer hands to work it, but necessitating the plough to work at right angles, or nearly so, to the engine, is therefore not well suited for uneven-sided fields. Howard's system, from the engine remaining stationary, does away with the strain on the engine moving along the soft headland, and the consequent poaching and compressing of the soil, but requiring two additional men to work it, and a large extent of rope. It is also better adapted for fields of an irregular shape, as the plough with the moveable snatch-blocks and anchors will work in any position.

"5th. The committee are also of opinion that on a large farm having a comparatively flat surface, with fields of not less than twenty acres, as nearly square as possible, and free from stones or other obstacles, and where three or four pairs of horses can be dispensed with, that steam cultivation will probably be highly beneficial as an auxiliary to horse power, as the work can be done with greater celerity and the ground cropped at the proper time, whereby an increased return would be likely to ensue. On a smaller extent of land there does not seem to be sufficient scope for the profitable employment of a steam plough.

"6th. The committee consider that further experience of steam cultivation in Scotland is necessary, in order to ascertain the actual expense of it, and the endurance of the engines and apparatus. On all the farms which they have inspected the machinery is comparatively new, and it is not to be expected that much outlay should be required to keep it in good order."

The Hon. GEORGE WALDEGRAVE LESLIE asked whether the committee was to be continued? Since last year an important improvement had been made in connection with double-furrow ploughs. If he mistook not, when the Thomson india-rubber tire-wheeled engine was put before these double-furrow ploughs, it was found to be an improved form of steam cultivation. He could not help thinking that, if the committee was to be continued, it would be desirable to get some infor-

mation regarding the appliance of steam engines to the double-furrow plough.

The CHAIRMAN said the Society were obliged to the gentleman who had put the question, and if he would write out his question in detail the Society could have no objection to answer it. The committee had given all the information they had obtained on the subject. There were experiments going on just now in most parts of the country with regard to double-furrow ploughs, and the information as to their results varied. He believed, however, that very much depended upon the soils in which they were used. They were frequently too heavy for two horses, and three were required.

Mr. LESLIE said that the reason he had mentioned the matter was that Mr. Fowler, whose plough had been so much praised, had taken great pains in the matter, and had improved Pirie's double-furrow plough very much. He considered that the experiments which had been made of Thomson's engines had been satisfactory so far as they had gone, and he understood that by their application to double-furrow ploughs a considerable saving could be effected.

The CHAIRMAN asked what the hon. gentleman wished the Society to do? Did he wish that the matter should be referred to the special committee for steam cultivation?

Mr. LESLIE said he should like to direct the observation of the committee to Thomson's india-rubber tire-wheeled engine.

The SECRETARY stated that the committee had exhausted their remit, and they now ceased to exist, but he had no doubt the suggestion would be at once taken into consideration by the directors.

Mr. WILSON (Edington Mains) said he had taken great interest in steam cultivation, and it was now nearly three years since he had worked Fowler's double engine, and it had given great satisfaction. Before getting it he made inquiries at those who had used it, and felt encouraged to go into the matter. He knew very well a great deal of the land he farmed was full of large stones, and he had a good deal of apprehension that he would meet with much difficulty in that direction. He was glad, however, to say that when it came to be dealt with in practice there was no such serious difficulty as was anticipated. In the land encumbered with large boulders there was no breakage except in the shares with which the plough was fitted. So far as the experiment had gone, it had yielded him very great satisfaction indeed. With regard to the matter suggested by the hon. gentleman, he must say that, judging from his experience, he had no hope of seeing any good done by steam cultivation with the engine travelling over the ground. When he required to take an engine diagonally across a field after it was cultivated by the powerful steam apparatus, they could always very well see the track of the engine; and to go over the whole surface of the ground with a ponderous engine, would only result in undoing what they had done. He thought the double-furrow plough was well adapted for fitting into the steam cultivator. In that way they could reduce the number of horses which were kept on a farm and were employed in working these double-furrow ploughs, and would overtake a large quantity of the seed furrow work which might not be so conveniently at all times overtaken by the steam tackle. The one being exceedingly well adapted to fit into the other, a man going into a new concern would economise his outlay very considerably by purchasing a stock of these along with his steam tackle. He thought that the proposal for an engine to move over the surface of the ground was in the wrong direction altogether. He had lain aside three pairs of horses by using the steam tackle.

Professor RANKINE thought it should be ascertained as a matter of fact whether engines with india-rubber tirewheels actually pressed on the ground so as to produce an injurious effect. His own impression was that they did not. They had been seen to pass over soft substances on the street without injury, as, for instance, a potato or a carrot; and having regard to the yielding nature of the tire, it was reasonable to suppose there could not be any great impression on the ground. However, that was a matter to be obtained by exact observation.

Mr. SMITH (Whittingham) said that Mr. Wilson had referred to an important point in speaking of the obstacles in the way of the steam plough. He thought it would be well to know from Mr. Wilson how deep the ordinary furrows

made by the steam ploughs were where the large stones existed.

Mr. WILSON said that where the soils were suitable for being worked, he had usually ploughed in the autumn stable land, or rather dug it, about a foot deep. But he might say, further, that in the fields which he knew had the greatest quantity of stones, he had been going over them with the ordinary subsoil plough, worked by horses, removing stones. Many of the fields had not been previously gone over with the subsoil plough, and in these no such serious inconvenience was met with as might be supposed. In fact, he had seen more breakage with a pair of horse ploughs—breakage in chains and swingle-trees—than with the steam plough, which went over the ground amazingly.

The CHAIRMAN: What kind of soil is it?

Mr. WILSON: Strong loam.

The CHAIRMAN: Drained?

Mr. WILSON: Yes; drained.

Sir W. STIRLING MAXWELL: Among how many horses have you effected the saving of three pair?

Mr. WILSON: Eleven pair.

Professor WILSON said, in reference to the subject to which their attention had been directed by the Hon. Waldegrave Leslie, it was only a question of the force and power required—whether it required more power for an engine to move itself across a field with a plough attached to it, or to transmit its force through tackle, like Mr. Fowler's and Mr. Howard's, for the purpose of dragging the implement up and down. These matters were tested very critically at the meeting of the Royal Agricultural Society at Leeds in 1861, and a report was made by the judges that the amount of power consumed in transmitting the force through a series of those tackles to the implement was infinitely less than what was required to move the engine along the ground, dragging the implement after it. He thought with Mr. Wilson they would be going entirely backwards if they adopted these engines, and that the experiments to which he had referred had set the question at rest. Mr. Thomson's engine was an admirable one for certain purposes, but he could not conceive it would abviate these difficulties and lessen the force required to draw an implement through the soil. The amount of power required to be transmitted through a series of wire ropes was much less than experienced engineers thought it would be.

The CHAIRMAN said he thought it right to remind the meeting that the instructions to the committee confined them in their investigations to the county of East Lothian, and they were not expected to go to other parts of the country. With regard to the question of engines going over the ground, his own experience was that it was quite difficult enough to get the engine to move over the ground without the plough. As to the depth in East Lothian, the greatest power seemed to be able to get down 12 inches, and his fancy was 14. He had asked several makers of implements if they could tell how the force was affected by the depth. Supposing a power to be exerted at a depth of 12 inches, what would be the power at 13, 14, or 15 inches? However, he could get no answer. It was a very interesting subject the diminution of the expenditure in the cultivation of land, whether it be by steam power or horses. To make three horses accomplish what four did previously was a very important matter. He thought that the committee would be very glad to take advantage of Mr. Waldegrave Leslie's proposition.

The Duke of Buccleuch moved—"That the special committee on steam cultivation be renewed, and that the question of double-furrow ploughs drawn by Thomson's indiarubber tire-wheeled engines be considered; and that the committee also take into their consideration generally the subject of cultivation by steam." He thought it would be very desirable to have all the information they could get on the subject. He had only one suggestion to make, and that was that the committee should not be restricted to any one portion of the country in making their investigations, but, if necessary, might go across the Border, and see what had been done there.

The motion was then agreed to; and, on the suggestion of the Duke of Buccleuch, it was agreed to remit to the directors to draw up details for the guidance of the committee.

Mr. GILLON (Walkhouse), said that, as convener of the Veterinary Committee, he had to report that Mr. Wm. Duns, veterinary surgeon, Dunbar, had been appointed to fill the

Chair of Cattle Pathology. Mr. Duns was a graduate of the Edinburgh Veterinary College, and had studied under Professors Dick, Strangeways, and Dalzell, and had obtained his diploma in 1863. Since then Mr. Duns had been in constant active practice. He (Mr. Gillon) might be allowed to state that, in this instance, a very able man had been appointed, and he had no doubt that Mr. Duns would be a credit to the college to which he belonged, as well as a great advantage to the public whom he would serve. The winter session of the college of 1869-70 was opened on the 1st November by the magistrates of Edinburgh, on which occasion Principal Williams delivered his introductory address. The attendance at the college had greatly increased in number—there being now ninety-five students. This number had never before been approached. It was also gratifying to know that the students were of a superior class to what they used to be, and were very orderly and well conducted. Several of the students had come from a distance—from England, Ireland, and Canada, and some even from New Zealand. He thought that said a good deal for the fame of their College abroad. The practice of clinical surgery, which he regarded as one of the foremost branches in veterinary science, had been more and more in practice lately than it had been for many years previously. He was sorry that the accommodation for the proper practice of this branch was very defective in the College; but how that was to be remedied it was not for him to say. The committee and the board of directors had had before them a representation from the Royal College of Veterinary Surgeons, London, regarding the preliminary examination of students, and asking the support of the society in the matter. Although the committee were fully agreed as to the advantages of a scheme of preliminary examination, yet, after carefully considering the whole matter, they were of opinion that the society should not take the matter up, but leave it to be settled entirely by the different teaching schools.

Mr. LESLIE asked whether the question of shoeing horses had been under the notice of the committee?

Mr. GILLON said that had not yet been before the committee; but he thought it was a subject that the committee should certainly take up. So far as his experience of thirty years went, he thought they had not arrived at a proper method for shoeing horses. He had taken some trouble in looking over the new systems proposed. The best that he had seen was the Charlier system which had been brought out in Paris. It had been tried to a great extent with omnibus horses—no fewer than 5,000 or 6,000 were working under the system—and it was found to work admirably. Whether it would do for hunters and roadsters he could not say. The advantage of this method was that it put the horses' feet into a more natural position than could possibly be the case with the shoe at present in general use. He observed that the society offered a prize for the best method of shoeing horses, with special reference to those systems recently introduced. The prize would consist of a medium gold medal or five sovereigns, so that they would have a chance of getting a good deal of information on the subject. He believed that Principal Williams was to bring out a new system of horse shoeing.

Principal WILLIAMS said he had had some experience of the Charlier system, and might say briefly that for hunters and light saddle horses, and for horses not required to be very hard worked, it stood pre-eminent over any other system. For omnibus horses and horses on the road, the Charlier shoe would have to be made with steel; it wore out too quickly. At present, in the case of these horses, the shoe went away in the course of a few days at the toe. For hunters he could recommend it with confidence to those present.

The CHAIRMAN asked Principal Williams if there was any general system of shoeing horses that he could recommend?

Principal WILLIAMS said the whole secret of horse-shoeing lay in the fact that the foot should not be mutilated, but left as whole as possible. It should be left sufficiently strong to protect the internal and sensitive parts. If this were done the form of the shoe would be a matter of secondary importance.

Sir W. STIRLING-MAXWELL asked if the Charlier system was not adopted in the French cavalry?

Principal WILLIAMS said he could not testify as to the Charlier shoe having been adopted in the French cavalry regiments; but he knew that at Chatham a graduate of the Edinburgh College had introduced the Charlier shoe, and with great success.

Mr. LAMLEN said a large number of cavalry regiments in France had adopted the Charlier shoe by order of the Emperor, and a large number of the omnibus horses in Paris had worn it for two months.

Principal WILLIAMS said that to make the Charlier shoe generally adaptable all that was required was to tip it with steel round the toe to prevent it wearing. If that were done they would have a revolution in horse-shoeing.

The SECRETARY stated that the members were aware that the directors had given leave of absence to Dr. Anderson, the society's chemist, in consequence of his having to spend the winter in the south of England, on account of his health. He read the following report on the work of the chemical department during the past year, sent by Dr. Anderson:—"In reporting on the work of the chemical department, I believe I may say that in no previous year has the work been so large and varied. The number of analyses made for members of the society has amounted to no less than 379, embracing the analyses of soils, waters, manures, feeding stuffs, and, in fact, all the ordinary articles of agricultural consumption. This exceeds the analyses made by Dr. Voelcker for the Royal Agricultural Society, although the number of members of that society exceeds that of the Highland and Agricultural Society by more than 1,000. The experience of the year's operations has been, on the whole, satisfactory; and though cases of adulteration are still too numerous, I think it may be said that some improvement in the quality of manufactured manures is slowly becoming manifest. One of the most troublesome matters in this respect lies in the great difference in the quality of different manufactured manures, none of which can be described as adulterated in the strict sense of that word, but which differ so greatly that, though sold at the same price, one may be worth £1, £2, or even £3 per ton more than the other. This occurs to such an extent that by the judicious choice of manure the farmer can often effect a very material economy, and numerous cases have occurred in which £10, £20, and £30 have been in this way saved on comparatively small purchases of manure. During the past season the series of experiments extending over a rotation have been continued, and a set of experiments on the action of different manures on the potato have been successfully carried out. For some time past the state of my health has been such that, acting under the advice of my medical friends, I have been compelled to obtain from the directors leave of absence from the active work of the laboratory. I have, however, taken care to make such arrangements that the work has been carried on without interruption, and that I am able to exercise a close supervision over all that is done. All the letters relating to analyses are sent to me, so that I may determine the exact nature of the analysis necessary to supply the information required. The analysis, when finished, passes through my hands, so that I am able to give my opinion on any matters of interest or importance which it reveals. On the state of my health I am glad to be able to give a favourable report, for though I have had a pretty severe illness during the greater part of December and the present month, which had somewhat retarded my general progress, my medical advisers consider that I have made as much progress as could be expected, that my case must be very tedious, and that I must not attempt to engage in active work for some time. There is one point on which I am compelled to ask the indulgence of the society. I had hoped to have published the results of the field experiments in the Transactions for this year, but my illness during December, which is the very time during which the reports must be drawn up, has made it quite impossible for me to do this, and I am most reluctantly compelled to ask permission to postpone this until next year. As regards the rotation experiments, I believe it will even be advisable that they should be postponed till quite complete, when the results will be much more useful and instructive than if they are published in a fragmentary form at the end of each season, and I would leave it to the society to decide whether this course should be adopted. The potato experiments, of course, I shall put together as soon as possible."

THOMAS ANDERSON.

January 18, 1870."

Mr. WALKER (Bowland) reported that the following premiums had been awarded for reports on subjects connected with the science and practice of agriculture since the general meeting in June:

1. The gold medal or £10 to William Alfred Gibb,

Gillwell Park, Sewardstone, Essex, for a Report on the Hot Blast Fan used in Harvesting.

2. The gold medal or £10 to William Wallace Hoxier of Tannochside, Bellahill, Glasgow, for a Report on Agricultural Drainage.

3. The gold medal or £10 to Robert Hutchison of Carlowie, Kirkliston, for a Report on the Diets of English Agricultural Labourers.

4. The gold medal or £10 to George Malcolm, factor, Invergarry, Inverness-shire, for a Report on Striking the Fairs Prices.

5. The gold medal or £10 to the late William Paterson, Union Street, Dundee, for a Report on Propagating New Varieties of Potatoes.

6. The gold medal or £10 to Patrick Shirreff, Haddington, for a Report on the Means employed by him for Obtaining a New Variety of Wheat called "King Richard."

7. The gold medal or £10 to N. P. Stewart, Cemaes, Llanrwst, North Wales, for a Report on Dipping, Pouring, and Smearing Sheep.

8. The medium gold medal or £5 to George Armatage, M.R.C.V.S., Linslade, Leighton Buzzard, Beds, for a Report on the Duties of the Veterinary Surgeon in Examining Horses as to Soundness.

9. The medium gold medal or £5 to said George Armatage for a Report on Veterinary Contracts.

10. The medium gold medal or £5 to Robert Laidlaw, Chapelhope, Selkirkshire, for a Report on Dipping, Pouring, and Smearing Sheep.

11. The medium gold medal or £5 to John Milne, Laithers, Turrif, for a Report on the Agriculture of Aberdeenshire and Banffshire.

12. The medium gold medal or £5 to Andrew Spreull, M.R.C.V.S., Milngavie, Glasgow, for a Report on the Duties of the Veterinary Surgeon in Examining Horses as to Soundness.

Mr. WALKER also stated that the directors had resolved to publish the Report on Agricultural Drainage, by Mr. Hoxier (No. 2 of the above list), in a separate form for sale, so as to place it within the reach of all interested in such operations.

Mr. WALKER further reported that the following premiums had been suggested for competition in 1870 and subsequent years:

On the agriculture of East Lothian	£30
On the agriculture of Inverness-shire	30
On ancient farming customs in Scotland	20
On autumn manuring	20
On land manuring	5
On manures produced by different kinds of feeding	20
On manures made with and without cover	20
On covering grain crops in harvest	10
On improved varieties of agricultural plants	10
On failures of the wheat crop	5
On the comparative productiveness of potatoes	10
On the comparative productiveness of turnips	10
On the cultivation of cabbage as a field crop	10
On vegetable productions of India, China, and America	10
On the best modes of housing fattening cattle	20
On different descriptions of food for stock	20
On disinfecting agents for stock	10
On the operation of the Contagious Diseases (Animals) Act, 1869	10
On the different modes of shoeing horses	5
On lambing	10
On transporting butcher-meat	5
On vessels used for transporting milk from country districts	5
On rural economy abroad susceptible of being introduced into Scotland	10
On the general improvement of estates by proprietors	10
On the reclamation of waste land by tillage by proprietor or tenant £10, £5, and silver medal	
On the improvement of natural pasture without tillage	10
On the invention or improvement of implements of husbandry	50

The report was approved of.

Professor BALFOUR reported that the following premiums had been awarded in the department of Woods and Forests during the past half-year:—

1. The medium gold medal or £5 to Robert Hutchison, of

Carlowrie, Kirkliston, for a Report on the Effects of the Dry Season 1868 on Trees and Shrubs.

2 The minor gold medal to John Blaikie Webster, forester, to Sir William Verner, Bart., Church Hill, Verner's Bridge, Moy, Ireland, for a Report on the Growth of the roots of Coniferous Trees after Felling.

3. The silver medal to the author of a Report on the Effects of the Dry Season 1868 on Trees and Shrubs, bearing the motto "Hortus Sicca."

Professor BALFOUR further reported that it was proposed to offer the following premiums for competition in 1870:—

On extensive planting by proprietors	£10
On the general management of plantations	10
On planting on exposed or barren tracts	10
On the value for economical purposes of Corsican fir	5
On forest trees of recent introduction	5
On home-grown timber as compared with foreign	5
On continental modes of forestry	10
On prices of forest produce	5
On effects of dry season of 1869 on trees and shrubs	5
On seedlings of conifers	5

The report was approved of.

TRANSACTIONS OF THE SOCIETY.

Mr. IRVINE, of Drum, reported that the next number of the Society's "Transactions," being No. 5 of the Fourth Series, would be published in February, and that it would contain the following prize reports:—

1. On the Agriculture of Aberdeenshire and Banffshire, by James Black.
2. On American and Canadian Trees, by John E. Brown.
3. On Pleuro-pneumonia, by George Armatage.
4. On the Diseases of Forest Trees, by John B. Webster.
5. On the Management of Poultry, by Robert Hutchison.
6. On the Corsican Fir, by John Morrison.
7. On the comparative Advantages of Spring or Autumn Manuring, by John Allan.
8. On the Formation and Management of Young Plantations, by Robert E. Brown.
9. On Sanitary Arrangements for Stock, by William Brown, jun.
10. On the varieties of Poplar best suited to the Climate of Scotland, by Robert Hutchison.
11. On Propagating New Varieties of Potatoes, by the late William Paterson.
12. On the Improvement of the Farm of Quarryhead, by James Stevenson.
13. On Forest Trees of Recent Introduction, by Robert Hutchison.
14. On the Cultivation of Cabbage as a Field Crop, by Gilbert Murray.
15. On Striking the Fairs Prices in Scotland, by George Malcolm.
16. On the Duties of the Veterinary Surgeon in Examining Horses as to Soundness, by George Armatage.
17. On the Same Subject, by James Spruell.
18. On Planting on Exposed or Barren Tracts, by C. Y. Michie.

And any other prize reports the directors may be enabled to publish. The Transactions will contain the report by the Special Committee on the various systems of cultivating land by steam-power in East Lothian—the proceedings at the board and general meetings—the premiums awarded in 1869, and of those offered in 1870—the accounts of the income and expenditure of the society for 1868-69, and other official documents.

The following communication from the Board of Trade was submitted:

"Office of Committee of Privy Council for Trade, 18th Jan. 1870.

"Sir,—I am directed by the Lords of the Committee of Privy Council for Trade to transmit to you, for the information of the Highland and Agricultural Society of Scotland, and for the purpose of being made public, the enclosed analysis and report upon the guano at Guanape Islands, which have been received through the Secretary of State for Foreign Affairs.—I am, Sir, your obedient servant,

"LOUIS MALLT.

"The Secretary of Highland and Agricultural Society of Scotland."

"The guano of the Guanape Islands partakes of a composition varying much according to locality and depth. In general, on the north as well as on the south island, the superficial strata exposed to the vicissitudes of the atmosphere are deficient in soluble salts, and consequently in ammoniac, augmenting the proportion of phosphate of lime. In the lower strata, on the contrary, the quantity of ammoniacal salts augments, thus diminishing the phosphate of lime. It is probable that by the action which has dissolved the ammoniacal salts of the superficial strata it may have penetrated by infiltration into the strata underneath, thus increasing the richness of the latter, so that in the end the ammoniac, which forms the most valuable principle of guano, is not lost, being concentrated as it is in the deeper layers of guano.

"In the southern island the change is manifested in a manner still more evident, as of the three samples that have been analysed, the most superficial contains only 7.562 per cent. of ammoniac, and in the sample extracted from a greater depth the ammoniac contained in 100 parts of guano rises to 18.820, a greater quantity than is contained in the best guano of the Chincha Islands.

"This last is formed almost entirely 95.000 of ammoniacal salts, soluble in water, consisting in greater part in oxalate and urate of ammonia, and should not be considered as a variety of guano, but as a combination of the soluble parts of the guano which appear to have been separated by the action of water.

"This sample, although possessing a strong ammoniacal smell equal to the guanos of the best quality, differs, nevertheless, through its other physical characteristics, presenting itself under the form of a pulverulent homogeneous matter of a more pronounced yellow colour than that of common guano, and with a crystalline structure only to be perceived through the medium of a microscope.

"If the bed of this material is in reality seven feet in thickness, according to Mr. Harris, who extracted the samples, it appears to me that a greater advantage could be obtained by selling this material to certain manufacturers of chemical productions, as liquid ammonia, oxalate of ammonia, or uric acid could be extracted with much facility for the manufacture of the colouring matter called 'murexide.'

"As this sample is very rich in ammonia, and very poor, on the contrary, in phosphate of lime, containing less than 5.100 of this salt, it could not be employed with advantage in agriculture, one of the principal elements being wanting for plants; and in case it could not be sold, as was suggested, to manufacturers of chemical productions, it could be utilised very well by mixing it with the guano from the Lobos Islands, which in general contains a strong proportion of phosphate of lime, and, *per contra*, is very poor in ammonia. By mixing the material in question, this guano would be improved, and would cause the value of the guano of the Lobos Islands to be enhanced, equalising it with the guano of good quality.

"Some of the samples of guano from Guanape subjected to analysis contain a strong proportion of water, so that, when the guano is pounded in a mortar, with the object of rendering it more homogeneous before proceeding to analyse it, it collects and forms a really sticky paste.

"At first sight, it would be said that this guano had been wetted; but, recognising the great hygrometric power which guano has, and knowing that the sample in question had been extracted in winter-time, when the atmosphere of the coast is almost entirely saturated with water, the great quantity of moisture which it contains is easily explained. I myself at another period made some experiments for studying the hygrometric power of guano, by keeping exposed to the open air a certain weighed quantity of guano; and I have beheld it increase or diminish in weight according as the weather was more or less dry.

"The element which is of most value in guano after the ammonia is phosphoric acid; but, as is known, almost the whole of the phosphoric acid contained in the guano is combined with lime, forming a phosphate of lime-tri-basico, not very soluble in water, and consequently absorbed with difficulty by plants.

"Various chemists who busy themselves with the study of guano have thought, and with justice, that by rendering the phosphoric acid contained in guano more soluble in water, and consequently easier to be absorbed by plants, the value of this material would be augmented.

"So, for many years, Mr. Neabit advised mixing guano with sulphuric acid, the which, by uniting itself with part of the lime, leaves free a part of phosphoric acid, which forms with the other portion of the lime a phosphate acid easily soluble in water. Mr. Richardson put this theory in practice, and asked for a patent for the transformation and amelioration of guano.

"Now, as not the whole quantity of phosphoric acid contained in guano is found in a state insoluble, under the form of tri-phosphate of lime, I have deemed it necessary in the analysis which I have made to make known likewise the

proportion of soluble phosphoric acid which the guano of Guanape contains." [The results of the analyses were given in an elaborate table.]

Two communications which had been received from the Board of Trade were laid upon the table. One was on the culture of the beetroot, and the other a number of reports on the cultivation of flax on the continent, which reports had been received at the Foreign Office.

On the motion of the Duke of Buccleuch, a vote of thanks was given to the Chairman, and the meeting separated,

LANDLORD AND TENANT IN SHROPSHIRE.

At the dinner of the Shropshire Chamber of Agriculture, Sir BALDWIN LEIGHTON said: On the bench magistrates had often no easy tasks to perform—they had to hear both sides of a question; and, upon the most contradictory evidence say which was right. He believed the magistrates always acted in such cases to the best of their judgment; and he also believed they had thus earned the good opinions of the public. If they did not succeed in maintaining their good opinions they (the magistrates) must fall. Among the theories of the present day some were good and some bad—some were as wild as wildness could run. Some persons clamoured for paid magistrates; but the advantage to be derived from such appointments was not plain. If they had a stipendiary magistrate they might, perhaps, get one man who would do the work very well, and another would do it as badly. It was not every lawyer who knew so much of agricultural law, if he might so term it, as their present magistracy. A stipendiary magistrate might be born and bred in London, or some other large town: and in many cases would not even be acquainted with the language of the agricultural districts—he would have to inquire what was a "cratch" and in what condition a man was when he was "clammed." In this way, from not knowing the Welsh language, he (Sir Baldwin Leighton) experienced great difficulty in a neighbouring county (Montgomery) during the nine years he was Chairman of the Court of Quarter Sessions in that county.

Colonel CORRETT said: Those who knew anything about the London markets and about prices knew the difficulties the producer had to labour under when the supply exceeded demand, and the cattle could not be driven away from the market alive. Butchers then gave any price they liked. He had been informed by a farmer in that county that he had lost £5 a-head on cattle in this manner. And was the consumer benefited by this state of things? Certainly not, for they found that the stock sent up was not usually excellent, and they must, he thought, attribute it to the fact he had mentioned—that proprietors were unwilling to risk the loss upon their stock by sending it to that particular market. This was an instance of what might be done by well-considered measures of the Chambers of Agriculture, and he thought it a point that should receive their attention. He urged that nothing could be done in relation to any question by mere discussion. They must take the example of the Chamber of Commerce in urging on the cause of "Reciprocity," and apply it to themselves, before the next session, in relation to the subject of local taxation. He recommended the further agitation of this question, expressing his belief that unless further pressure were put upon Parliament they would not be likely to get the question considered this session.

Lord BRADFORD, the president, said he could not help thinking that a considerable amount of gratitude was due from the agriculturists of that county to some of the agricultural associations in the county that they had had before that society was originated, and some of which still existed. He referred particularly to one association with which he had been connected—the Wenlock Farmers' Club. He thought that that society deserved a word of acknowledgment. He was present a short time at the last meeting of the Chamber, but he was, unfortunately, rather late, and as he did not hear the whole of the discussion, he did not take any part in it. The discussion was as to whether the Chamber should select for their next discussion the subject of roads and highways, or that of ground game. For his own part he should

have had no objection to have discussed either subject, but if he had voted at all, he should have given his vote for the question of highways. He thought this an important matter, and one that should be discussed at once, as they had reason to suppose that the Secretary of State intended to bring in a bill upon the subject, and it was most desirable that the opinion of the local Chamber should be known. He repeated that the subject was of great importance, and one that was deserving of the attention of Chambers of Agriculture, for he was afraid the bill passed a few years ago had not tended to lower the rates throughout the country. There was no doubt, he thought, that the roads and highways of the country were in a most unsatisfactory condition—at least they were so in that part with which he was connected. There were other important matters that would require to be discussed by the Chamber. Among them was the great question of the sewage of towns, which was, at present, in its infancy. It was, of course, of more importance to those who lived in the neighbourhood of the large towns, but it was a growing question everywhere, and he thought the Chambers of Agriculture of the country may be of the greatest possible use by raising discussions upon it. There were certain things that were within the control of each individual; there were other things that required the co-operation and the union of the large body of farmers of that country. There were questions upon which public opinion may be said to have expressed itself, and which were ripe for legislation, and there were others that were not so. It was the former class of questions that were ripe for legislation, not the latter. Another very important question that Chambers of Agriculture should entertain was the great question of education. It, of course, came under this great question of local taxation, which, in fact, comprehended all the other questions that had been alluded to there that evening. He had observed the rather significant cheering just now when he alluded to the question of game, and here again he was rather inclined to take a leaf out of the book of his noble friend and distinguished predecessor, Lord Granville, who said that there was an old saying to the effect that a certain class of persons rushed in where angels feared to tread. He did not think he (the President) should have said one word in allusion to that, had he not within the last few days read a paragraph with regard to himself which had surprised him a good deal. It was to the effect that the "farmers of Shropshire would have an opportunity on Saturday next (that day) at Shrewsbury of expressing their views on this question, for Lord Bradford, one of the greatest game preservers in the county would preside at the dinner." He was not generally in the habit of taking notice of things of that sort, and as the author of the paragraph might be in the room at that very moment, it would be uncivil to his face to contradict him; but this he (the speaker) may say—he thought all those who knew him, knew pretty well that shooting was by no means what he may call his sport. He liked a day's shooting, as he thought his noble friend said last year, but the sport he indulged in—his sport—was fox-hunting. He cared little more for shooting than for the sake of his friends. He thought therefore that the man who wrote that paragraph did not know him very well. He would go further, hoping, however, they would forgive him for speaking so much of himself. He had frequently seen in the public press during the last twelve months paragraphs headed with large letters "An example to landlords," and all that sort of thing, which were to the effect that lord so-and-

so had done this or the other with reference to his game, and expressing a wish that others would follow the example. He had never troubled himself to make any answer to these things, but as he was now on his legs and speaking of himself, he would say that on those estates which he had inherited his tenants had now, and had before the land came into his possession, the liberty to kill rabbits whenever they liked. He found no fault with his tenantry for killing the rabbits, he was more inclined to find fault when he found too many than when he found too few. But he assured them he did not take to heart at all any little paragraph of that sort. He hoped the tenant farmers in that room would excuse him if he told them a little story, which, at all events, had the merit of being true. He was out hunting one day, not very long ago, with a pack of hounds, and going into one of the covers, the master was asked how it was that he drew that cover, and he said, "Because Mr. So-and-so asked me to do it, as the foxes were doing so much damage—they were eating all the rabbits" (laughter.) That was a fact. There were some who would like to have more rabbits, and some less; and for his own part he was certainly not in favour of too many. He would rather have foxes upon his property than any kind of game.

Mr. GEORGE CURETON said: I have much pleasure in responding to the toast of Agriculture. We all know its importance. It is, as a pursuit, a pleasant and invigorating one, but not a very profitable one. We farmers cannot make fortunes like those who are engaged in commerce. Circumstances put me into harness early. I have had forty years' servitude, therefore I may presume to be a practical farmer; and though we are called "clod-hopping farmers," if we, by intelligence and perseverance, with the use of the modern appliances, make two blades of grass grow where only one grew before, and produce two beasts where only one was produced before, I think we are worthy of our country. I do not generally agree with the would-be agricultural

leader, Mr. Mechi; but what he said lately, with regard to ploughing up and tilling the poor pastures of this country, I quite concur with, since the produce would be much increased thereby. I do hope every effort will be made to get the meeting of the Royal Agricultural Society here next year; and we shall see great strides made in the breeds of our live stock, and the vast improvement in agricultural machinery since 1845, when it was held here before. I should like to mention the very great improvement in the breed of Irish pigs, which I have had the opportunity of observing, having acted as judge frequently at the Royal Agricultural Shows in Ireland. Twenty years ago they used to drive along the Holyhead road, near which I live, to markets in England, ugly, long-legged animals, with slopping ears that would knot under their chins, and backs like a knife. Now the Irish pigs are of first-rate quality, and uniform in character and symmetry. The British farmer requires security for capital invested in permanent improvements, and other extraordinary judicious outlays. He wants relief in local taxation, by bringing other property to bear its fair share of the burden; he wants fairplay in free trade. As long as there is such an amount of taxation on his produce, in the shape of a malt-tax, I say the present state of the law is anomalous, and an injustice. He wants protection from the depredations of the ground game, which, in many instances, are very veracious and injurious to the tenant-farmer, and a loss to the community. I speak with some experience; and I say that however clever and careful a valuer is, he cannot arrive at a satisfactory result as to the estimate of the damage done by ground game. I do not speak feelingly on this subject; for my noble landlord, Lord Powis, allows me to kill the hares, and he hates the sight of a rabbit, so that I sustain no damage; and I only wish all landlords would follow his example. I believe if these privileges were conceded to the British farmer he would better his position, and produce more food for the increasing population of this country.

INOCULATION FOR PLEURO-PNEUMONIA.

At the meeting of the Council of the Norfolk Chamber of Agriculture, the following report was presented:

First report of the experiments of the inoculation of cattle for pleuro-pneumonia in Norfolk, commenced in November, 1869, by William Smith, M.R.C.V.S., Norwich.

Having been requested to report to you the progress made in the inoculation of cattle for pleuro-pneumonia which I have been conducting, the following detailed statements and observations are respectfully submitted for your consideration.

It is desirable to observe that as these experiments were all made on infected farms—indeed, in infected herds—they are open to objection, as at the time of operating, some of the animals, probably all that have taken it since the operation, may have been incubating the disease in the system, but this was an evil that could not, under existing circumstances, be avoided; agriculturists are not proverbial for readily adopting anything novel, and perhaps they are right; difficulty was found in obtaining the owner's consent to have the operation performed, even in infected herds, whilst in healthy ones, in no instance has the proposal to inoculate them met with success, although they were assured that it was highly improbable and next to impossible that by this means pleuro-pneumonia would be introduced into their herds; but who can be surprised at this? Individual exertions must be aided by a responsible body, and supplemented with means, if it be desired to thoroughly test the value of inoculation as a preventive of pleuro-pneumonia, and it must be done on a scale sufficiently comprehensive to enable us to form sound, practical, and definite opinions; half doing things in medical as well as in most other matters, leads only to confusion and error.

The subjoined details of the experiments follow each other in the order in which they were conducted, and were made with fresh lymph, selected from the lungs of animals suffering from a mild type of pleuro-pneumonia, in which only one lung was involved.

Experiment No. 1.—On November 11th were inoculated in

the tail, about three inches from the tip, eight Irish steers, at Griston, age 1 year, condition poor, unhealthy looking, registering a very high internal heat, in one the thermometer stood at 104° degs., and in others the reading was above 103° degs., as will be seen by reference to the table below. No local swelling or redness worth noticing followed the operation, or observable constitutional disturbance.

Register of internal heat of body at the time of operating, as indicated by Cassella's self-registering clinical thermometer:

Steer No. 1	102° 4.5	The normal heat
" 2	*103 3.5	in the ox being 102,
" 3	102 3.5	those steers marked
" 4	*103 1.5	with an asterisk in
" 5	103 4.5	the tables were con-
" 6	103 2.5	sidered suspicious.
" 7	104	
" 8	*103 2.5	

On November 19th, the owner, writing to inform me how his bullocks are, says: "I do not see any of them fall off in any way from the inoculation. On Wednesday (five days after the operation) I saw some fluid issuing from the spot where the inoculation was performed."

Experiment No. 2.—On November 17th, one bull at Thorpe St. Andrew, from an infected herd, was operated on, his two companions having died from pleuro-pneumonia, age 3 months, condition fair. Result to this date—unaffected, either locally or otherwise.

Experiment No. 3.—On November 23rd were inoculated eleven Irish steers from an infected herd at Beighton, age 2 to 3 years, condition fresh. No local specific action was set up in the tail. Result—three attacked, two of which were killed and one recovered.

Experiment No. 4.—On November 29th, ten steers from an infected herd at Bradfield, age 3 years, stall-fed, condition

forward. No heat or tenderness of the inoculated part of the tail or any observable effect followed. Result up to this time—all well.

Experiment No. 5.—On December 6th, nine steers from an infected herd at Beaham were operated on, age 3 years, condition forward. No local or other observable action ensued. Result—none attacked.

Experiment No. 6.—On December 7th, eighteen steers and stags, 1 and 2 years old, some fresh in condition and others poor, Irish bred. Result—before the end of the month three were attacked and six since, one badly diseased and died, four others were killed or died, and two recovered. These were part of an infected herd at Booton, to which further reference will be made.

Experiment No. 7.—On December 8th, twenty steers from an infected herd at Freethorpe, age 2 to 3 years, condition fresh. Result up to January 14th—all well. In this, as in the experiments which follow, no local or constitutional disturbance or sign of illness occurred after the operation, and it will not be necessary to repeat the observation.

Experiment No. 8.—On December 23rd, three Irish steers from an infected herd at Blodfield, aged 1½ year, condition fair. Result up to this date—healthy.

Experiment No. 9.—On December 30th, eight home-bred inoculated, of various sex and age, condition fair, from an infected herd at Brundall. Result up to January 14th—none attacked.

Register of internal heat on December 30, at the time of operating, and on January 2 and January 6, 1870.

Summary.—Inoculated, 87; attacked with pleuro-pneumonia, 12; died and slaughtered, 9; recovered wholly or partially, 3; remaining at present healthy, 75.

Thus we see that only 13 animals out of the 87 inoculated were attacked with pleuro-pneumonia and these I confidently believe, took the disease in a natural way, for these reasons, that they were not at all affected locally by the operation; and that inoculation for other contagious diseases in animals, such as small-pox in sheep, rinderpest, and foot-and-mouth disease in oxen, communicates the specific malady to 9ths or more of those operated upon in a form either mild or more or less violent.

Having already stated that these experiments were all made in infected herds, it is worthy of note that those subjected to the experiments numbered 6 and 9 had lost several animals from pleuro-pneumonia prior to the inoculation, in fact, the disease had been amongst them for some week, and in No. 6, four animals had died from parasitic disease of lungs as well as some from pleuro-pneumonia.

After these remarks it will be apparent that I do not attach much importance to the results of these experiments. They are, in my opinion, insufficient and incomplete. I think, however, they incontestably demonstrate two facts: 1st, that pleuro-pneumonia inoculation, when scientifically performed is a harmless operation, and not likely to cause an extension of the disease, and that the loss of animals' tails and other untoward effects, when they occur, are produced by the ignorance and want of skill of the inoculator; 2ndly, that it differs in most essential points from the conditions induced by inoculations in other contagious diseases, such as small-pox or cattle plague. In the inoculation for pleuro-pneumonia we have a total absence of the manifestations apparent in other inoculations; there are no local signs of its having taken, nor constitutional or febrile disturbance that can be detected, even though we call in the aid of that delicate instrument, the clinical thermometer, as proved by its readings in experiment No. 9, the particulars of which are in a tabulated form under it.

As no opportunity has occurred of examining the lungs after death of inoculated animals under circumstances favourable for the forming of a truthful opinion as to their condition,

it may yet be discovered that some morbid lesions, narrow exudation, so characteristic of pleuro-pneumonia, or traces of such, may exist as a consequence of inoculation, and in order to put this to the test, as well as the whole question of the prophylactic influence of the operation, I venture to suggest the following series of experiments.

Proposed Experiment No. 1.—That twelve young animals bred on a farm where pleuro-pneumonia has not existed for four years should be purchased, and inoculated, and that four should be slaughtered six weeks, four twelve weeks, and four sixteen weeks after the operation, for the purpose of examining minutely the cavity of the chest, pleura, and lungs.

Proposed Experiment No. 2.—That 100 young oxen, bred under the same conditions as in proposition No. 1, should be purchased, and that 50 of them should be inoculated on the farm, and 10 of the inoculated, and 10 of the uninoculated should be sent into five infected herds, and kept on the premises, where practicable, for a period of from six to twelve months.

Proposed No. 3.—As it is a well-known fact that certain farms in this county have never, for the last fourteen or sixteen years, been without one or more cases of pleuro-pneumonia occurring annually amongst the herds, that the proprietors of such farms shall be induced to have all fresh animals introduced upon them for the next four years inoculated.

Before concluding this report, I beg to thank Mr. J. D. Overed, M.B.C.V.S., of Blodfield, for the ready and valuable assistance he has rendered in the prosecution of the foregoing experiments.

To Professor Gamgee, of London, thanks are especially due for the kind presentation of two clinical thermometers of very delicate construction, which he had regulated at Greenwich, before sending them for the purpose of these experiments, Norwich, Jan. 15 1870.

THE LANDLORDS AT THE CENTRAL CHAMBER OF AGRICULTURE.

At the dinner of the Hereford Chamber of Agriculture,

Mr. VAUGHAN, of Brobury Court, said as he had been honoured by them in being sent to the Central Chamber as their deputed member, he must say that he had seen something at the meetings of the Central Chamber which did not please him. He thought the opinions of the deputed members did not have that force they ought to have. All was not right. And he felt that he should not be doing his duty to the Chamber he had the honour of representing at the Central Chamber if he did not say what struck him as not carrying out what that Central Chamber ought to be. The Central Chamber was supposed to consist of a Council of its own members and of the deputed members sent by the country chambers. But what did he find? He found (with all due deference to Sir Herbert Croft and Sir Joseph Bailey) the parliamentary element very strong there. He alluded to the peers and the members of the House of Commons who were present. He thought that the discussions which took place were a good deal toned down, if he might so speak, by the repeated interpolations of the peers and the members of the House of Commons who were present. There was one gentleman—Mr. Corrance—he was like an irrepressible "Jack-in-the-box." He was continually upon his legs; he was eleven times upon his legs in one discussion, and it was difficult to put in a word. Now he understood that by the laws constituting the Central Chamber it consisted of the Council and the deputed members, and that the peers and members of the House of Commons who attended the meetings were there to "read, mark, learn, and inwardly digest;" and in their respective places in Parliament give effect, if they thought right, to the decisions of the county chambers which were expressed through the Central Chamber.

Mr. BURROWS said that he could in some respects bear out the remarks of Mr. Vaughan with regard to the meetings of the Central Chamber. He was present at one meeting of the Central Chamber, and he was then convinced that what Mr. Vaughan had stated was true. At the meeting he referred to the same question was brought forward, and the landlord interest was much too strong. Peers, members of the House

of Commons addressed the meeting, and landlord after landlord spoke strongly against any further legislation upon the subject. There were amendments to be brought forward there, which he thought were shelved. He knew that Mr. Duckham had an amendment which he was to second, but the chairman (Mr. C. S. Read) held up a lot of amendments and asked the meeting if they wanted any more? The meeting seemed to think that they had had enough; but he thought that meeting broke up without properly discussing the question. He thought the tenant-farmer interest required to be more strongly represented at that meeting, and he hoped that upon future occasions it would be.

QUESTIONS FOR CHAMBERS OF AGRICULTURE.

At the meeting of the East Suffolk Chamber of Agriculture last month, a list of subjects selected by the Central Chamber having been read, Mr. NEWSON GARRETT said there was one question upon which he felt strongly, and he did not know whether this was the right time to introduce it. He wished some one more immediately connected with agriculture, but not more deeply interested in it, should have spoken upon it. He saw a good many farmers present, and he maintained that it was one in which they, and we all, ought to feel an interest. He did not intend to make a long speech, but he sincerely hoped that before long, before many months were over, that this great and important subject would be discussed. Since he had been sitting there gentlemen had given notices of motions; he thought he should like to mention the subject of the game laws (applause). This was an important matter, and he knew well that it was a dangerous one. It required to be handled very gently and smoothly. He only hoped it might fall to his lot, if the subject should be discussed, to say nothing that might be held personal, or cause an ill-feeling one between another; but still he did feel, and he knew it was a feeling that was gaining ground, that this question should be discussed at this Chamber. He would, therefore, move that the Chamber should consider "The present state of the Game Laws, their bearing upon the tenant farmers and the agriculture of the country in general." As far as the tenant farmers were concerned they were quite able, if they would do it, to protect their own interest, and he was quite sure there were many outside who were not so immediately connected and interested in the land who felt for them, and were anxious and willing to express their feelings and opinions upon this important subject. He felt, himself, that it would do good—at any rate it would ventilate a principle that required ventilation—and he only hoped and trusted that if it was brought before the meeting that it would be done with every degree of good feeling, and every desire to do good, not only to the tenant farmers, but to the country at large. He would then propose that a motion should be placed upon the paper to consider the present state of the game laws. He would do the best he could.

Mr. R. L. EVERETT seconded the motion, remarking that observations had been made about the Chamber not having brought forward the subject. There would no doubt be two opinions on the question, that a good deal would be said, and that a very interesting evening would be spent in talking over the game laws.

The resolution, as follows, was then unanimously carried:

"That this Chamber should consider the present state of the game laws, and their bearing on tenant farmers, on agriculture, and the country at large."

It was decided that this question should be brought forward on the 12th of April.

Mr. R. L. EVERETT said there was one suggestion he should like to make, viz., that the Central Chamber should arrange a deputation to the Chancellor of the Exchequer, and suggest that a part of the surplus should be given towards a reduction of the malt-tax. There was no doubt but that there would be a large surplus, and he (Mr. Everett) could not see why agriculturists should leave off agitating the question; he could not understand, especially after a report of the House of Commons, why the tax should not be put on a different footing. He thought they, as farmers, would do well to urge the Central Chamber to send a deputation to Mr. Lowe.

Mr. J. M. DAWSON seconded Mr. Everett's proposition, which was agreed to in this form: "That the Central Committee should organize a deputation to wait upon the Chancellor of the Exchequer on the subject of the repeal of the malt-tax, before the introduction of the Budget."

OVER-DOING IT.

At the meeting of the Herefordshire Chamber of Agriculture,

The SECRETARY said a communication had been received from the Central Chamber stating that there would be a meeting of that body in London on the 8th of February to consider "the best mode of providing for the future maintenance of turnpike roads and highways," and requesting this Chamber to send a deputed member to the meeting. On looking through the minutes of the meetings held last year, he found that there had been two discussions upon this subject, and that on the 21st of April the following resolutions were passed: "(1) That the Government be requested to bring in a measure for the total abolition of turnpike gates. (2) That the future repair of turnpike roads be borne with that of the other parish roads by each Highway Board by district rate, and that the same be assisted by grant from the Consolidated Fund. (3) That the debt of any trust be met by rate upon the owners of property." On the 19th of May those resolutions were again brought forward and discussed, and signed by the Chairman. If the resolutions now met the views of the Chamber, it would be desirable to appoint some gentleman to attend the meeting of the Central Chamber on the 8th of February, and he (the Secretary) would furnish him with a copy of the resolutions as expressive of the opinion of this Chamber, unless it was thought advisable to discuss the subject again.

Mr. BIRCH thought it would be quite necessary to do so. He saw that many Chambers had discussed the question again and complained loudly of the Highway Act, and he was sure there was cause of complaint in this district.

Several members were of opinion that as the question had been twice discussed, it would be unnecessary to re-discuss it, and it was decided on a majority of ten to one not to re-open the question.

THE MEETING OF THE ROYAL AGRICULTURAL SOCIETY IN 1871.—At the ordinary monthly meeting of the Shropshire Chamber of Agriculture, in Shrewsbury, Mr. John Bazeley in the chair, the principal business was "To consider what steps should be taken to promote the visit of the Royal Agricultural Society of England to Shrewsbury in 1871." A letter was read from the Town Clerk of Shrewsbury, suggesting a conference between the Corporation and the Chamber. On the motion of General Herbert, it was agreed "That the chairman be requested to write to the Lord Lieutenant of the County, in the name of the Shropshire Chamber of Agriculture, to suggest for his Lordship's consideration the desirableness of calling a county meeting on the 15th inst. (the day of the annual dinner of the Chamber), for the purpose of considering what steps should be taken to ensure the meeting of the Royal Agricultural Society of England "for 1871, being held at Shrewsbury if thought desirable." Also that the Mayor of Shrewsbury have a copy of the above resolution, and that the co-operation of the Town Council be invited in the matter."

It was stated at the dinner of the Herefordshire Chamber, that the discussion of the game evil was fairly, or very unfairly, swamped by the landlords on the Council of the Central Chamber. It is, indeed, now said that an Anti-Game-Law League is about to be formed, whose action in Parliament and elsewhere will be entirely independent of the Chamber of Agriculture. When the cattle disease was rife, it became the business, not of the Central Chamber, but a special Cattle Defence Association, to see to this matter in Parliament; and most likely, when there is anything else to do, "the work will be put out" again.

FARM CAPITAL.

The following paper was read by Mr. J. J. MCHI, at the last meeting of the Framlingham Farmers' Club: Accepting the invitation given to me by your intelligent club to say a few words about agricultural capital, I approach the subject with a full appreciation of the difficulty of removing long-cherished convictions based upon the practice of our forefathers, who were, no doubt, fully entitled to our respect and confidence; but the circumstances under which they lived are now changed, and are still rapidly changing, so that we, as landlords and farmers, must deal with these altered conditions in a commercial spirit, which always adapts itself to the peculiar influences that at the time surround it. Who would have thought in my time, some 60 odd years ago, that the smoke from coal would be made to flow in underground channels, and re-appear, almost magically, in our chambers as a blazing light, sending to the shades the gloomy flickerings of the venerable oil-lamp, with its contemporary dips and moulds. Again, we have no longer to beat about for three weeks within sight of Dublin harbour in the face of an adverse wind, but can now make sure our voyage with almost unerring regularity. Lovers can exchange soft words, and merchants may buy or sell cargoes at lightning speed beneath the broad Atlantic. In fact, in my early days we had no ocean steamers or railways, no gas, no telegraphs or photographs, no penny post, no cabs, omnibuses, or police; but we had to boose over our port wine because the coaches could only accommodate 20 people, who had, in many cases, to book their places a day or two previously, and then to travel at 7 or 8 miles per hour. The new broadsheets of daily news were then puny slips, as cramped as were then our general education and literary opportunities. But mighty steam has changed all this. And we can and must advance at modern not ancient speed. I feel sure that you will agree with me in this view of our changed position, and that both you and your landlords will gradually but surely glide into the profitable stream of steam-driven progress. It is wrong to charge agriculture as especially prejudiced and attached to old customs, for, some two or three centuries ago, our Lord Mayor and Corporation of London petitioned the King to prevent the introduction and consumption of coal, as its smoke created such a nuisance! Now, the supply to the metropolitan district exceeds 5,000,000 of tons annually. Our principal towns once opposed the approach of railways as a nuisance, and have since repented of their folly. Even now there are people who won't believe that the safest place you can live in all your life is constantly travelling in a first-class railway carriage. It is, in my opinion, too much the custom, and a great mistake, to congratulate each other upon improvements that have been made in our agriculture, rather than to lament over that which remains undone, and for which there can be no excuse, seeing that there is no lack of customers for our produce (one-third of our food comes from abroad), and that our overflowing and rapidly increasing capital goes to encourage foreign enterprises, instead of being applied to the increased fertilisation of our soil. The bright examples of agricultural progress which are so frequently brought to public notice in bold relief rest as mere specks upon a most extensive and dark back-ground of bad and imperfect farming. It must be so, or we should produce more per acre than the admitted average of less than £4. Remember that I do not speak of Suffolk, or any particular county, but of the 45 millions of available acres that constitute the agricultural area of the United Kingdom, as returned annually to the Board of Trade. It is not in my nature to despond, rather the contrary; but I consider it a duty to endeavour to awaken public attention to that paramount national question, the means of increasing the food and employment of the people by a profitable and enlarged investment of capital. I am not a believer in large farms, for they are already, most of them, too large by more than one-half for the capital employed both by landlord and tenant. A farm can never be too large where the tenant's capital is £20 per acre, and where the landlord has effected necessary permanent improvements. My own small farm of 170 acres is an illustration of what

should be done—for with a tenant's capital of £16 per acre there has been, for several years, an annual surplus of more than £600, available for rent and profit, after paying every other expense. In this case the landlord (myself) bought the land for £23 per acre, and expended nearly as much in drainage, building, roads, removal of trees and fences, and other improvements, thus raising the rent to 40s. per acre. The time will come when a landowner will be appreciated, not by the number of his acres, but by the amount of his rent-roll, the latter representing a high rate of rent and a well-ordered estate. Steam-power has so multiplied population by affording increased and more profitable manufacturing employment, that we are now no longer in the primitive pastoral period, when the people were few and the acres many. All this is being rapidly reversed:

Year.	Population.	Available. Acres.
In 1800.....	10,000,000	45,000,000
In 1869.....	32,000,000	45,000,000

These thriving and hungry millions who throng our manufacturing districts demand of us agriculturists (I mean landlords and their tenants) a change of practice, and a progressive increase of food more in accordance with the rapidly-enlarging demand for it. A considerable area of land is passing into the hands of manufacturing and commercial millionaires, who, happily, in many cases, bring to bear upon the soil the power of intelligence and capital, unfettered by a previous attachment to antique customs. I consider it a disgrace to us that, wanting 10 million quarters of foreign wheat annually, besides other grain, we permit one-half of our acreage (22,000,000 of acres) to remain in primitive pasturage, producing a minimum of food, and employing a minimum of labour. I know that there is a strong feeling in favour of permanent pasture, but when I see that I can, not infrequently, realize on my poor farm as much as from £15 to £26 per acre in corn and straw, I feel vexed that those 22,000,000 of acres of permanent pasture should be starving the people by producing probably not more than 40s. to 50s. worth of food per acre. I now proceed to inquire, *How much is the Capital of British Agriculture?* I mean the landowners' and tenants' capital? Taking the average of the kingdom, the 45,000,000 of acres returned to the Board of Trade, the landowners' capital would probably be £33 per acre, or £1,500,000,000, besides the value of timber, possibly £30,000,000 more. The average rent is probably 25s. per acre, or about £56,000,000 annually. *The Farmers' Capital can hardly reach £5 per acre, or £227,000,000.* I have taken no account of the mountains, wastes, &c., which are not enumerated in the Board of Trade returns. My estimate of the farmers' capital may appear low to arable farmers, but we must not forget that 22,500,000 acres (half the land) are in permanent pasture, much of it very neglected, and employing little labour or capital. The gross saleable produce I estimate as under £4 per acre, or £189,000,000; probably £3 12s. would be nearer the truth. Additional landowners' capital will be some day required in the matter of town sewage, for on to the land it must ultimately go. Probably it will be dealt with (when landowners can agree) on the principle of the great Fen drainage by Acts of Parliament and local commissioners. The London sewage will be indeed a great affair, for it takes the annual average produce of 20,000 acres, landlord's measure, to feed the population of London for only one day, and about an equal quantity weekly to feed the horses of London. One can judge from this how great must be the daily manurial power and value of the London sewage. Farmers will then have sewer meters (as manufacturers have water meters), and take their supply according to their requirements. If I am asked by landowners where the capital is to come from for necessary improvements, I point to the several land improvement and drainage companies which are overwhelmed with unused capital, seeking for employment in this agricultural channel that remains, as yet, almost unopened to it. Covered yards, cottages, farm-houses, roads, drainage,

&c., may be all effected, even to the extent of £20 to £30 per acre, without any outlay on the part of the landowner, and at a moderate annual charge, divisible in equitable proportions between landowner and tenant, to both of whom it must prove a source of profit, as well as to the nation a boon. When I purchased my poor land in 1841, it cost me £23 per acre. I invested nearly that sum in drainage, roads, and buildings, clearances, and machinery, so that I have to pay myself 40s. per acre annual rent. Last year, 1868, I sold one field of white wheat for £23 per acre, and the straw for an additional £3 10s. My farm capital is £16 per acre, invested as follows on the 31st December last (see details at p. 45 of my book, published recently by Routledge and Co., Ludgate Hill, London):

	£	s.	d.
Live stock	6	10	0
Farm houses	1	1	0
Tillages, manure, &c.	3	15	6
Implements and machinery	2	10	0
Hay, corn, &c., unsold	3	5	0
Per acre	16	1	6

This may appear to you a large sum, especially for live stock and tillages, but I want you to believe that the considerable amount invested in live stock, fed mostly on purchased food, is the very key to my profit, and to those large and frequent crops which many people will hardly credit until they see them. The costly tillages arise from very deep cultivation, and a much larger dose of rich cake and corn manure than is generally administered. It is thus that I grow 40 tons of mangold per acre, as I have done this year; and this, too, accounts for my frequently growing from 6 to 8 quarters of wheat per acre, and on my highly manured clover less two heavy crops of wheat in succession (the second crop rivet wheat). Some of you have on various occasions seen my crops, and can form your own opinions. Although not a good season, my best two fields of white wheat have yielded 6 quarters per acre, and my barley (grown after 6 quarters of white wheat) was thrashed last week, and yielded over 6½ quarters per acre, sold at 38s. per quarter. The quantity of seed wheat drilled was one bushel per acre, and of barley 6 pecks per acre. This has not been a good year for arable land farmers, for the crops vary a good deal, and the price of wheat is now very low. Stock breeders have the best of it this year, for the abundant crops of roots and hay have caused a large demand for their store stock at higher prices. They, however, suffered severely in 1868 from the drought, while the arable farmers prospered, especially on heavy lands. My experience has taught me that on such farms as mine £16 will pay a much better profit on one acre than on two. Poor farms require more manure, and consequently more live stock than rich farms, and, of course, much food must be provided that did not grow on the farm, thus adding to its fertility. Many Norfolk and Lincolnshire farmers have from £20 to £30 per acre capital. They are thus enabled to hold their corn a proper time, keep plenty of stock, and purchase food for it. I could do better than I do now had I £20 to £25 per acre capital; £16 is not enough. I presume, from my knowledge of Suffolk, that its general tenants' capital does not exceed £7 to £8 per acre, and that there is ample room for investment of landlords' capital in drainage, buildings, and other necessary improvements. It is true that you have more grass-land than I have (I have only 1½ acres), but I predict that the introduction of steam cultivation will annually diminish the area of pasture, especially of pasture in heavy land. Steam cultivation will place land in a more favourable position than it has hitherto had. The advantages of ample capital are obvious. You can buy when other people are obliged to sell, and sell when other people are compelled to buy, and can maintain ample stock and machinery. Ample capital sometimes leads farmers to hold their corn when they ought to sell it. As a safe maxim, I would say, always hold wheat at 40s. per quarter, but sell when it is at 60s. I have known of a good deal of money lost by farmers who always hold their corn for a higher price than buyers are willing to give. We see, in consequence, old corn-stacks riddled by rats and mice, and when thrashed, minus the grain. Capital with judgment is an immense power, and only fails when it is overstrained. If I am asked how I would employ additional capital, I reply that our subsoil, im-

mediately below the ploughed soil, is now a mass of undisturbed poverty, unenriched, unmanured, and unfit for the roots of plants; we dare not, in its present unwholesome state, bring it to the surface and bury our top soil; we should, therefore, uncover the subsoil by ridging or ploughing together the top soil, and incorporate with the subsoil an immense quantity of rich manure. To obtain this additional manure, a large capital must be invested in live stock and purchased food. In fact, to farm to the greatest advantage, the soil and subsoil, to the depth of 3 feet, should be well manured; now we only manure the top 5 or 6 inches. Our root and green crops can never be over-manured, for they feed in the deep subsoil when in a fit condition. Market gardeners understand this well; and around the metropolis they easily grow 70 tons of mangol per acre, and other crops in proportion. This system of large capital and highly manuring has an immediate bearing upon the growth of beetroot either for sugar or for distilling. In times to come factories for both purposes will be greatly multiplied. Landowners are very anxious on this point. They say to me, "It is all very well for our tenants to sell off their roots, but how about the restoration of fertility?" My reply is, "Let them farm as they like, provided they invest a capital of £15 to £20 per acre, one-half of it invested in cake-fed live stock." The frequent growth of red clover and swedes is rendered impossible by the absence of manure in the subsoil. Baron Liebig, and the late Rev. Samuel Smith, of Lois Weedon, well understood this. Before free-trade, "Down corn, down horn" was the motto. Since then bread, milk, butter, and cheese have increased in price, and are free from the fluctuations that occasionally, as at present, depress the price of wheat. Let us, therefore, go in for more live stock and more capital. The return of the beet pulp to the soil restores most of its inorganic elements, and they to some extent prevent exhaustion. Live-stock purchased cheaply in July, when feed is scarce, pays well for carrying on with a little cut straw, cake, &c., until the root season commences. Poor land may be almost immediately made fertile by heavily folding with sheep, consuming £10 or £15 worth per acre of cake, corn, hay, roots, &c., not the produce of the land on which the sheep are placed: supposing that there should be a loss even of £3 to £5 per acre, great will be the after gain. This system requires capital; but where there is capital, it is by far cheaper than guano or other artificial. Where my 40 tons of mangol per acre grew this year, the land was autumn-manured with shed manure at the rate of £20 worth of cake, &c., consumed for every acre manured, and some guano in addition. This is what I call capital farming, as well as farming with sufficient capital. It is the true way to make land pay. The land of England is generally not one-third manured. One can never over-cultivate or over-manure, for a root crop especially, when, like mine, it follows two wheat crops, and is followed by another wheat crop. There is no need for landowners to tie down tenants who farm with a capital of £20 to £30 per acre. Their land must improve under such circumstances. Your sugar-beet land should be all richly manured and very deeply cultivated before Christmas, and only scarified and guanoed before sowing in April. This I find is the best plan for mangol. My farm is all arable except 1½ acres of permanent pasture. I have no fence except an external one, and I am very glad to hear that some of your distinguished landowners have realized the propriety of removing many of those fences and pollard trees that disfigure the country and prevent the farmer from deriving the full benefit of his land; for, you know, he has to pay rent for the ground occupied by fences, trees, and their roots, besides suffering a diminution in his crops. A farmer of 600 acres told me the other day that he offered his landlord an extra £100 per annum rent, provided he might clear the ground of those obnoxious and unprofitable obstructions to good tillage. Yet his offer was declined, although the growth of the timber did not come to one-fourth of the proffered annual increase of rent. Now that 30-horse power steam-engines are cultivating 36 acres per day, we shall soon see such clearances as at one time was never anticipated. Saw an implement-maker to me at the show last week, and a farmer declined to buy one of the great traction-engines because his gateways were too narrow. The implement maker wondered, smiled sarcastically, and thought many things—some of which he told me. Remember, that while I advocate ample fields untimbered, I strongly urge the formation of plant-

tions or belts at intervals, not only as shelter, but as breeding places for birds—the farmer's friends. We must remember that as we clear and drain the country we not only produce a drier and warmer climate, but our buildings should be strong enough to resist the gales that will sweep less interruptedly over the country. By the way, speaking of tillage, my dependable friend, the Rev. Mr. C., plumbed the depth of the cultivation at Beesot, near Farringdon, the other day, and found it to be 30 inches. It was done by two of Fowler's 30-horse power engines, and when the land is cross cultivated the depth is to be 3 feet—in preparation for sugar-beet. My shallow-drainage friends may as well take a hint, and consider whether even 4 feet will be deep enough when the 50-horse engines are put to work. We are on the eve of many great changes—your middle-class college, so creditable to Suffolk, is doing much to enlighten the rising generation of agriculturists. The Royal Agricultural College at Cirencester, in which I, many years ago, took a great interest, has now become an established institution, granting diplomas for agricultural efficiency, and sending forth men learned in the theory as well as practice of agriculture. I begin therefore to hope that the pervasion to a lecture which I delivered at Chelmsford in 1853 (seventeen years ago) may soon be in some degree realized, I therefore give it as a conclusion to this long paper, which you have heard so patiently, trusting that I may ultimately be found a true prophet: “I see in perspective a railway activity pervading agriculture. The time is coming when farms will be squared, trees removed, and game moderated; when tramways will intersect estates, and one horse will draw to market the load of four; when the sewage of our towns will ebb back to its original source; when the waters of our rivers and drains will be applied to the irrigation of fields; when our millers will use steam instead of water; when our farmers and their children will be better educated and rank higher in the social scale; when our labourers will be better housed, taught, and fed. Then will the blundering rudeness and clumsiness of ignorance be exchanged for the watchfulness and thought of an enlightened intelligence; then will the fractional calculations of profit outweigh the fears of cost; then will antiquated territorial legalities be superseded by personal responsibility, identity, and possession. I see all this in the distance: it is a mere question of time. I see mighty engines on railwayed open fields, tearing up furrows a yard deep, making the land look like a sea. I see those hungry earthy masses saturated and immediately fertilised with the sewage of towns. I see ample evaporation and facile percolation. Tottering and dilapidated farmhouses will give way to permanent and convenient homesteads; the pinching economy of a parsimonious and pernicious system will be exchanged for liberal views and large operations; capital will develop its giant strength, unfettered by seigniorial restrictions; agriculture, commerce, and manufactures will unite by the ties of a great common interest and common intelligence for the good of our people and for the honour of this great nation.”

Mr. R. GARRARD, Brundish, would like to ask Mr. Mechi how it is possible for a tenant to put £30 an acre upon the land if he has no security for it. He thought Mr. Mechi's estimate of the amount of capital a tenant had invested in the land rather low, and that it was something like £10 or £15 an acre in this district. At present the amount of capital lying in the valuation between incoming and outgoing tenants was very large, but if the tenant were to put three times the amount of capital in the land of course the covenant would be very much higher, and he doubted whether he would see his capital back again.

Mr. G. LING, Bedford, had for a long time thought their friend Mechi was simply a beacon for farmers to beware of, and that opinion was confirmed that night. Mr. Mechi talked to them about putting a lot of capital into the land, but he had seen his own figures to the effect that he gave £35 an acre for the Tiptree Hall farm, and then laid out nearly £50 an acre as landlord's permanent improvements, and then it was to have £30 an acre as tenant's capital, which amounted on to £13,000 on the 160 acres. His profits were £600 a year at the extreme, which was 8 per cent. for his money, including landlord's and tenant's capital, and a man must be a very bad judge of laying out his capital if he could not make it pay more than 5 per cent. The landlord would claim 2½, 3, or some wanted 4 per cent. for his outlay, and if that was paid to the landlord how was the tenant to live? Mr. Mechi was a self-appointed

teacher of farmers—and he had got a lot of very inept pupils. If he (Mr. Ling) wanted information he would prefer to go to a man who farmed 300 acres at say 30s. an acre rent and 10s. more for rates and tithes, and who, he knew, had brought up 8 or 10 children and given them a good education. He always looked on Mr. Mechi as an amateur farmer, which was the same as an amateur runner or sculler—he did not do it for gain. There was no difficulty in making a lot of fat bullocks—it could be done with money, but the question was how about the pay? It was all very well to talk about growing food for the people, but what he (Mr. Ling) said was, “Let us grow food for ourselves first.”

Mr. H. BIRNELL said he had opposed Mr. Mechi as much as any one who had met him as little as he, but he did not term him a self-appointed instructor. He thought Mr. Mechi a very willing adviser, but they were at liberty to take or reject his advice—but they should be very careful to do so in the same kindly and good-tempered manner in which it was given. For his own part, if he were not restricted as to capital, he should examine some of Mr. Mechi's suggestions very closely before he should think himself justified in using capital as he advised. Questions such as those raised in Mr. Mechi's paper could hardly be discussed except on paper, and therefore, they would reserve their judgment on many points. He understood Mr. Mechi to say that the employment of more capital would answer better on poor land than good land. Now between Wilford Bridge and Oxford quay was a large quantity of very poor land worth perhaps 7s. an acre, and he would ask whether it would pay better to put £15 or £20 an acre capital on that land than on such land as they would find in a circuit of a mile and a half round Framlingham Castle, the rent of which would be 37s. an acre. His own opinion was that if this great capital were used, the better the land that it was used on the better return would be obtained. It was quite true that many things which Mr. Mechi told them years ago had been accomplished, but he did not doubt on many, which he once thought quite as necessary, extended experience had led him to alter his mind.

Mr. MECHI: No.

Mr. BIRNELL said then Mr. Mechi was more fortunate than most men who could see further than their fellows.

Mr. MECHI hoped some gentleman would say what he thought was a sufficient tenant's capital in Suffolk.

Mr. LING said about here it was generally thought that a man who farmed his land best with the least money was the best farmer. The man who made a little money go a long way was the best. The tenant's capital in this district might be set at about £10 an acre on the average.

Mr. MECHI wished some gentlemen to speak about deep cultivation.

Mr. G. GOODWIN said Mr. Mechi said the natural result of the application of steam to agriculture would be to reduce the amount of pasture, and he based that assertion on the statement that he could produce a much larger amount of food from cultivated arable than from the pastures. He (Mr. Goodwin) did not deny that, but they must look to their balance-sheet for the results. Mr. Mechi said that with the pastures but a small amount of labour was required. Now, labour was a very serious item in their expenditure, amounting to from 30s. to 40s. an acre. At the present time stock brought more remunerative prices than some cereal crops, and it became a serious question whether it was desirable to continue to reduce the amount of pasture land at the ratio which had up to the present prevailed, for it was by means of the pastures that stock was kept. Another effect of Mr. Mechi's proposal would be to sweep away altogether an immense mass of men now engaged in agriculture, and the result would be that the competition for occupations would be much less and the landlords would not get such high rents; and he must confess he regarded it as a thing to be contemplated with much seriousness when it would put *hors de combat* a fourth or a third of the present tenantry of the kingdom. Twenty or thirty pounds an acre was a formidable amount to invest in an occupation. Mr. Garrard had said the valuation paid by the incoming tenant is so much capital lying dead instead of being lively; and if more capital were put in the land of course the valuation would be heavier. Mr. Mechi contemplated getting rid of all fences and trees and substituting steam for the present source of labour. By so doing he would, of course, sweep off the horses and men too, for he told them one man could work

an engine of 30 or 50 horse-power, whereas it would take 25 men to work 50 horses. Then what an enormous amount of capital would be sunk in these engines.

Mr. MECCHI said the pair of 30-horse engines to which he had alluded with the tackle cost £4,500, and they were doing cultivation 10 inches deep at 2s. 6d. an acre, after paying interest on the outlay. These enormous engines were used as a matter of economy, and it was considered that 50-horse-power engines would be cheaper than 30.

Mr. GOODWYN did not suppose any one in this neighbourhood had any experience of cultivating two or three feet deep, but some years ago sub-soiling was the fashion on poor lands, and in some of them the result seemed to be that all fertilizing power was done away with for several years. He supposed Mr. Mechi would accompany this with heavy manuring, and it seemed to him almost impossible to make manure enough for that.

Mr. MECCHI: Not with the present amount of capital in live stock.

Mr. GOODWYN said Mr. Mechi spoke of keeping more stock per acre, and yet he sold the straw off the farm. Then he did not mix the manure the animals made with straw?

Mr. MECCHI said when under the boards he did not.

Mr. GOODWYN said at present the difficulty was to find straw enough. He knew Mr. Mechi would turn round and tell him that he should cover the yards; but Mr. Mechi should tell the landlords to do that.

Mr. D. SMITH (Parham) asked Mr. Mechi if he considered a bushel of wheat and six pecks of barley the maximum amount of seed per acre.

Mr. MECCHI said he did, except when sown very late on light land, and then he sometimes went to five pecks of wheat; but five-sixths of his wheat was sown with a bushel, and barley invariably with six pecks.

Mr. SMITH asked whether Mr. Mechi could keep cattle cheaper on arable land than on permanent pasture?

Mr. P. READ (Framlingham) argued that closely connected with the question of agricultural capital was that of labour, and asked if labour was unenlightened and unskilful, what was the use of their capital? He urged the necessity for a better system of education, and as an illustration of the necessity, said if an agricultural labourer came to his shop and had to pull off a glove, the operation took him a quarter of an hour, whilst the tradesman stood looking on, whilst if he wanted a boot-lace and had to take off a boot, a good half-hour was wasted. Education would make them quicker, and without it we should be left in the rear by other European countries. He would like to ask Mr. Mechi how many men he would think it advisable to have on a hundred acres of land, what wages he paid them, and whether he liked an intelligent or a stupid man best. Because there were farmers in this district who positively preferred stupid labourers.

Mr. MECCHI said he paid ordinary labourers 10s. and horse-men 11s. a week, but almost all his work was done by the piece, and a man earned about £35 a year.

Mr. READ said that was about £5 a year more than they made here ["No, no"]. He would take it 10s. a week and the harvest.

Mr. MECCHI said his men earned about £6 for their harvest, and beer worth about 15s. besides. They had to cut the wheat and see it on the stack at 11s. 6d. an acre, and most of his crop was wheat, and at that rate they earned the £6 in about a month.

Mr. READ contended that the present scale of wages was insufficient to maintain labourers so as to enable them to do a good day's work and educate their children.

Mr. CORRANCE, M.P. (President) said if the whole of the appliances Mr. Mechi had mentioned were brought to bear the tenant's capital would not be less than £40 an acre, and he wanted to see how far that view was borne out. Whether it was practice was a totally different thing. Theory must precede practice, and the one unanswerable argument against putting that amount of capital in the land was that they had not got it. It would, however, be useful to see whether the possibility existed for the appliance of that amount of capital if they had it, and with that object he would follow Mr. Mechi through a few of his statements. He agreed that capital goes abroad to increase the profits of foreigners and employ foreign labourers in competition with us when we buy foreign produce. Mr. Mechi further said this was a pity, because not more than

£4 or £5 per acre was employed on the average on the land under cultivation, and that statement was borne out by the estimate of M. Laverne in 1854, which was £3 7s. per acre, half the land being pasture. This miserable sum might bring something back; and from a series of calculations he had made he had come to the conclusion that £4 capital per acre would bring a return of not more than 5 per cent., and he defied them to make more. That was, supposing the farm contained 100 acres and the capital was £400, they would get the not very adequate remuneration of £20. If they had £600, and the per-centage were the same, they would get £36—not a labourer's wages—and if £1,000 the profit would be £50. Mr. Mechi said they might go to £15, £20, or £25 an acre. Now, to apply the test. He had assumed that the return would be 5 per cent. whatever the amount of capital employed, but he had come to the conclusion that under circumstances as at present existing, without the large supply of town manure, without the assistance of landlords in the way of covered yards and the other improvements Mr. Mechi advocated, £15 per acre might, under the best possible management, produce 15 per cent. profit. That was the maximum he thought could be obtained under the present circumstances, and if they employed a greater capital they would find the profit would be diminished, and with £20 an acre they could not get more than 10 per cent., and with £25 an acre they would go down to 7 or 5 per cent. Applying this to a farm of 100 acres with £500 employed, the profit would be £25; with £1,000 capital it would be, at 10 per cent., £100; with £1,500, at 15 per cent., £225; with £2,000 they had passed the maximum and found the scale descending, and would only get 10 per cent., or £200; and with £2,500 they would only get 5 per cent., or £75.

Mr. MECCHI: How are you going to crop it?

The PRESIDENT: I am taking it under existing conditions, without all this additional artificial manure and buildings.

Mr. MECCHI: I cannot deal with the existing conditions.

The PRESIDENT said he did not say Mr. Mechi could, and this calculation did not controvert Mr. Mechi's position under the circumstances he wished to bring about. Mr. Mechi told them he had £16 per acre capital, and that it produced a sufficient per-centage.

Mr. MECCHI said he first allowed 40s. an acre rent, and then had an average profit of 12½ per cent., it being sometimes 8 and sometimes 15.

Mr. CORRANCE then referred to the question of breaking up the pastures, the policy of which he questioned until both landlord and tenant had the capital, reminding them that farms with a fair amount of pasture were most sought after, and that every acre of grass which is broken up made more capital and more labour a necessity. Their grass might be very poor, and badly treated, but it was an immense accommodation. As to the description of land to which more capital might be most advantageously applied, he thought the poor clay lands could so be improved in a greater ratio than others. The next question was, where the additional capital is to come from, and why landlords would not take the money which the Land Drainage Companies would lead on such easy terms? The deficiency of capital arose first from the fact that the farming class, as a class, were not wealthy. A commercial man with money hesitated about taking a farm, knowing that he will lose a great deal of money before he can get an adequate result. The main reason rested on the principle of political economy—that capital will go where it meets an adequate return and where the conditions are favourable to its employment. What would produce these favourable conditions? High profits, low taxation good security. A man with a thousand pounds would not put it into a business in which a very moderate profit of 8, 9, or 10 per cent. was made and he was exposed to an enormous burden of taxation, some special and some general; the local burdens alone falling on landlord and tenant amounting to no less than £57 15s. 10d. on every hundred acres. If a man had a sum in the funds at 3, 4, or 5 per cent. would he put it into farming, where the profits would not be greater and he would have to pay such heavy rates? He would say, "No, I will employ my capital in brewing or some other trade, for why should I make it subject to such a tax?" Then, another reason was the low security. This brought him to the question of leases and agreements. His idea of security was that the tenant should not invest any capital at all over which his landlord could have any absolute command. It was monstrous that

a tenant on a yearly hire or short tenancy should bring in capital to be subject to the will of any other man. It seemed monstrous to him in these commercial days, though it did not twenty years back, when the state of things was more of a patriarchal nature, and they occasionally heard of a landlord at Christmas retaining his rent to a tenant who had been unfortunate, but they did not hear of that now. They stood on other relations altogether—business relations—and those relations ought to rest on a sound and solid foundation, and his conclusion was that all permanent improvements, such as farm buildings, &c., ought to be absolutely done by the landlord, if his capital permit, or if the security he could offer permit, for though he had not always capital, credit was equally good. It we could remove all the capital that the tenant has invested, not only here but in Ireland, on the security simply of good faith, and put it on the landlord's back, we could stand on thoroughly sound relations. To give the tenant adequate security for the capital he would invest he would always give him four years to prepare to leave the occupation. That was the form of agreement that had been adopted on his father's estate, and if the tenant could see a good four years before him, to get a fresh occupation and prepare to leave that which he then held, he thought they would agree with him that there would be no necessity to talk about fixity of tenure or any such nonsense. There had been a total want of knowledge on this subject. He contended that if a landlord allowed a tenant to lay out £1,000 in permanent improvements on the estate he really alienated from himself a portion of the fee simple. Customs of the country had done a good work and were of enormous use, but only until the two parties could come to fair business-like working relations with each other. In conclusion he asked Mr. Mechi what inducement they could offer to bring capital out of the coffers of the wealthy men to be employed in the cultivation of the land?

Mr. BIDDALL said the president told them that the profits of farming ranged from 5 to 15 per cent., according to the amount of capital invested, and then he said that capitalists would not take money out of the banks or the funds where they got 2½ to 3 or 4 per cent. to put it in the land, because of the taxation. He (Mr. Biddell) thought if the commercial man knew he could make 10 per cent. of his money he would not be frightened by the taxation cry into letting it remain where it returned only 2½ or 3. Why did not capitalists come and invest their money in farming? Because they did not believe that it paid—they knew better, that was the reason.

Mr. MECCHI, in reply, said the real point at issue is whether it would be better in his case to put his £16 on one acre or two. He had arrived at the conclusion, from his experience, that the £16 will pay a better per centage on one acre than on two of his land, and he went further and said if he had £5 an acre more he could do better than now—he could buy his cattle and sell his corn when it suited best, could keep more stock, make more manure, and grow greater crops. Now, there was one difference between him and many of them. His landlord—and he always spoke kindly of him, for it was himself—(laughter) had done what the President said he ought. He had made the conditions favourable to the employment of capital. That was the most important word the President had said that evening. His (Mr. Mechi's) conditions were favourable for the employment of capital. Was that so as a rule? He said it was not. They were shut in by fences and trees, they had not covered yards in many cases, and many appliances were wanting, and he therefore asserted that the landlords had not put the land in a condition favourable to the employment of capital. His landlord had, and he paid him the fair interest of 4 per cent. or 40s. per acre instead of the 20s., which was about what it was worth before the farm was improved. They must compare the conditions as well as the operations, and he said if he had £16 an acre invested in their land he could not derive the same profit he did from his own, though he paid the higher rent for the improved conditions; and if he had to pay the diminished rent for his own land in its former unimproved state, he could not make the per centage he did now on his £16. Let us hope the time will come when landlords will think it right to put the land into this condition by their own capital, or that which they can get elsewhere. It was admitted that the average produce per acre was from £3 10s. to £4. That was unsatisfactory, and arose in a great

degree from what Mr. Goodwyn commended so much—poor grass-land, which was not estimated to produce more than from 40s. to 45s. per acre. It was said that grass-land required little labour, but the question was whether, if that land was broken up and farmed with a large capital, the return, after payment of the expenses in produce and profit, would not be greater than now. His experience was greatly in favour of arable land.

The PRESIDENT: Where is the capital to come from?

Mr. MECCHI would say to both landlord and tenant if they take 200 acres instead of 400 they would double the capital per acre directly. If a man with 200 acres would be content to take 100 with the same capital he now employs on 200 he would be much better off, and the same may be said of the landlord. Half the land in the kingdom is unimproved, and if they had less it would be better both for the tenants and the country generally. He reminded them that this was no longer a pastoral age. If he had all his land under pasture he might put all the capital he could on it but could not make it pay him. He knew pasture is acceptable because it employs very little labour and requires very little capital.

The PRESIDENT: What would you breed?

Mr. MECCHI: Where I can grow great crops of tares, and roots and other food. Never mind if you can give them plenty of food and air and not too much exercise.

The PRESIDENT: Can you breed in yards without grass?

Mr. MECCHI: To be sure; I have 30 calves a year.

Mr. BIDDALL: Where do the calves come from? (laughter.)

Mr. MECCHI: From the cows, of course (much laughter.)

Mr. BIDDALL: Where do the cows live?

Mr. MECCHI said it was not necessary to have pasture. Give the animals plenty of corn and cake and clover hay and so on, and they would produce as good animals as any one—in fact, he believed the best animals were not those produced on poor grass land, but as he had mentioned. He then alluded to restrictions, asking whether they thought if he had been tied down to a particular rotation suitable only to a small capital that he could put a large capital on the land with advantage? When they produced an enormous quantity of manure by the employment of large capital they produced large crops of roots, &c., which they could sell off the farm, but under their present conditions they could not sell those crops without diminishing the fertility of the land. Mr. Goodwyn professed a very great deal of feeling for the labourer, but he (Mr. Mechi) did not believe in it. Of course, Mr. Goodwyn had a kind feeling for the men in his employ, but if he could do with one-fourth of the number he would without a moment's hesitation.

Mr. GOODWYN: Of course I should.

Mr. MECCHI said: Then what became of the cry, "What are the labourers to do?" The farmers had to look to the cheapest way in which they could raise their produce. They had the natural and proper kind feeling towards the labourers they must of necessity employ, paid them according to the market, looked to their welfare, education, and so on; but don't tell him (Mr. Mechi) that they were afraid of not having employment for their labourers. What they wanted was to reduce the amount of labour (Hear, hear). The same was the case with horses. They had no love for their horses if they could supersede them by a cheaper power. If they now proposed to a manufacturer to put horses in a wheel to drive his machinery instead of steam, he would think they had gone back a hundred years, when a man wore his breeches three years instead of having a new pair every six months (laughter). The landlords had not according to modern principles done their duty. It was a failing on their part rather than a fault; but steam was changing all that, and he anticipated the time when there would be freedom of action and security of investment on the part of the tenant such as now existed to a great extent in Scotland. What had made Scotland, but nineteen years' leases and freedom of action? (Hear, hear). A Scotchman, if he could raise a good crop of potatoes, and it would pay him to send them to the London market, did so. The great point was that a tenant must not reduce the fertility of the soil below what it was when he took the land, and if his action is to increase rather than diminish it, he ought to be as free as air to produce that which is suitable to the requirements of the population. He treated all his farming transactions as a matter of business, and he said that it paid him best to raise 40 tons of mangold on one acre with one ploughing, one rent

rates, taxes, seeding, &c., than to grow the same quantity on two acres with these expenses doubled. Mr. Knatchbull told him he had seen 68 tons of mangold to the acre.

Rev. H. E. KNATCHBULL said he saw, at the Smithfield show, a sample of mangold certified to be part of a crop that weighed 100 tons to the acre. On inquiry he found the acre was an Irish one, which gave 66 tons to the English acre.

Mr. GOODWIN said Mr. Mechi misunderstood what he said about the labourers. He said breaking up the pasture would increase the demand for labour. As a matter of business he should reduce his farming to the least expense. He proposed a vote of thanks to Mr. Mechi.

Mr. MENCHI proposed a similar compliment to the President, and the meeting ended.

MIXED HUSBANDRY.

At a meeting of the Ballymahon Farmers' Club, the Hon. L. H. King Harman, President of the Club, in the Chair, Mr. John LUNEM said:—Mixed husbandry is what I have selected to bring before you in this paper, and as the notice I had for writing it was very short, and my time limited, my thoughts on the subject are expressed in a very cursory way. 1st., Is mixed husbandry necessary in good farming? I would answer in the affirmative, and say it is necessary. It is a fact patent to all that the population of Ireland is becoming less every year, and multitudes of the labouring classes are leaving our shores and seeking employment in other countries. By some this is considered a good omen for Ireland, by others bad. I confess I cannot see it to be a good omen to know that so many of Ireland's bravest sons should be driven from their native country to seek a home and employment in a foreign land; and whatever may be the causes at work to produce this sad effect, one cause must be apparent to all—want of mixed husbandry. It is said by many experienced farmers that tillage will not pay, and in many instances it is true, when it is carried on too extensively or in an injudicious manner; but the want of tillage has tended very much to the driving away from our country the labouring classes. In some of the counties of Ireland men are only employed to put in and take out the crops, and then during the winter months the same men are dismissed, having nothing to live on, and the consequence is a prolonged existence of misery, or else quit the country for one where they will have permanent employment. Mixed husbandry will give constant work to a certain number on a farm, whereas on large grass farms only a herd is employed, and the number of families who might be comfortably supported as labourers on this farm, must seek a home elsewhere. A happy combination of tillage with pasture creates employment and tends to keep the country from being depopulated. In travelling over many parts of the country one cannot but admire the rich pastures of the greenisle, with plentiful woodlands for shelter; yet whilst such scenery calls forth admiration, it produces in a reflective mind melancholy, to see nothing but cattle as the inhabitants of those places which the great Creator designed for human beings. It has been said by some competent authors that Ireland has abundant resources in the soil, if properly developed, to maintain eight millions of people; but whether such a number could be supported in comfort or not, we will not venture an opinion. On this, however, is certain, that mixed husbandry would support many more, and leave the farmer more happy and independent. Mixed husbandry is necessary for the judicious management of the farm. It is true that there are some farms so rich in pasture that to break them would be a mistake; but the large proportion of farms, especially where there is a limestone bottom, gather moss and completely choke the grasses. Top-dressing with lime compost or limestone gravel will do much to remove it for a while; but there is no effective cure but to break it, until the moss is completely rotted, and then lay it down again in good condition with best grasses. And this young sole will suit well for sheep pasture, as the grasses are much sweeter and more nutritious than the old ones. Some portions of the farm may not be adapted to pasture, but suit pretty well for tillage; and to keep such in pasture would be a great loss to the farmer. Large tracts of Ulster, for example, must be tilled, as the soil is not naturally adapted to grass, and large tracts even of our own country will not produce grass in such a measure as would warrant the occupier to adopt such as remunerative farming. Land that will not produce pasture should be tilled with such a rotation of crops as are suited to the subsoil, and mossy land should not be broken until the sod is rotted. In this way, if the land is well drained, it will be made to yield its increase,

and give comfort to employer and employed. Mixed husbandry is necessary for bringing to profit the stock on the farm. If a proper rotation of crops be observed it will give ample support to the whole stock of the farm. "I have a farm of very medium quality," said a good farmer once to me; "but yet I sell all fat in Dublin market, and rear all." Now, to follow this system, which I hold is a most profitable one, it is necessary to have mixed husbandry. On most farms the rearing of young stock is necessary, as the pastures are not rich enough to fatten, and if the young stock are to be kept until they pay well, there must be a sufficiency of food raised to support them. Turnips, mangels, cabbage, beans, carrots, flaxbolls, and oats are necessary to bring them to maturity for the market, and unless they are well fed they will not pay. A farmer in Ulster on a farm of eighty acres told me his soil was naturally poor, but he reared young stock and fed them every winter upon a little turnips and straw, with a small quantity of bruised oats mixed with flax bolls, until they were of age to fatten, and that every winter he had the number in the stalls that he reared, and although his farm was what might be called a high rent, yet by mixed husbandry upon it he was able to live comfortably and save nearly £100 per annum. Had he sold his young stock before they came to maturity he said he could have done nothing like save so much—that he would have had a hard struggle to make his rent. Mixed husbandry is necessary to realize the full amount of profit which the farm properly managed will yield in accordance with the state of the markets. Every year the variety of farm produce is varying, some portions of it will be high, some low, and thus the farmer always catches good prices for some of the produce; whereas if he is wholly dependent upon one kind of crop or stock he may be disappointed. A little sold of everything makes muckle, and if one thing does not pay, another will. Let there be as great a variety of crops as possible, but all of a real marketable value, and this in skilful hands will increase rotation of cropping, which will be good for the land. Keep down the weeds, and take out of the manure all the ingredients, so that none of them may be dormant in the earth. It will tend, we believe, on medium-sized farms and on small ones, more than any other system, to increase the purse. I have seen the large flowing river with its broad sheet of water emptying itself into the ocean, and how did it come to be so large. Trace it to its source and you will find that small—perhaps a spring, and the question arises, How came it to be so large? namely, by the tributaries poured into it. It is large from many sources. So we hold that tributaries from mixed husbandry swell the whole, and make the little a muckle. Let there be a proper system of pig feeding, cattle feeding, dairy farming, with a sufficiency of crops grown to support all, and some for the market. The result will be success and prosperity. Some may say all this appears very well on paper, but it is a different thing to carry it out. To such we say that every great discovery in science and art appeared first on paper. The steam engine appeared first in its plan upon paper; the great discovery of the telegraph, which now tends to the concentration of the whole earth, appeared first on paper, and so must all improvements in farming appear on paper. A proper plan, a good system, is more than half the success. A thing well begun is more than half finished; so with this system of farming. But a mixed system of husbandry is necessary to make a man a good farmer. His mind should be trained well in every department of agriculture, and when he begins to cultivate a variety of crops, he will get as much knowledge as possible about each species of crops, and that will lead him to read, inquire, and investigate until he has succeeded, and in his success he will carry on his investigation.

tions, in order to improve, knowing that there is no end to discoveries and improvements. This training is most useful to his own mind, adds happiness to him in his industry, and comfort in his prosperity. If the mind is only fixed upon one kind of farming, the training that it would otherwise have will be neglected; but if he cultivates a variety of farm produce, the mind will be upon the stretch to make the best of it. Mixed husbandry is necessary to suit the variety of soils on the same farm. There is frequently a great variety of soil and subsoil; one part is better adapted to one kind of crop than another, and thus, by the skilful adaptation of crop to soil and soil to crop, there is a more abundant supply. In the study of nature we find nothing but variety, and mankind is so formed that they live upon variety, and are made happy by variety. The eye is adapted to variety, and feasted with variety; we live upon variety, and the earth is made to yield this variety. In advocating mixed husbandry, we are only accommodating ourselves to nature, and endeavouring to produce that variety which nature has taught us to produce, and without which mankind could not live or be happy. Variety is a necessity of our nature, and there is a beautiful adaptation of the earth to this variety. As we study to be like nature and imitate nature, so do we become beautiful, profitable, and industrious; for nature is not only clothed with beauty, but it is both exceedingly profitable and industrious. Mixed husbandry is nature's imitation, excites to industry, and, as we shall try to show, is really profitable. It is a good maxim to learn well in all departments of business the arithmetic of profit and loss, and we agriculturists should ever keep this rule before us, as it ought to be the aim of every farmer to make everything pay. Farming for amusement and ornament may pay those who engage in it in a rich return of health, knowledge, and pleasure, but not in money. It is money that most farmers want, and the question is, will mixed husbandry yield that. On this subject there is, no doubt, a great variety of sentiment, and almost every man forms his own opinion from his experience; but an opinion to be correct and influential must be founded on intelligent experience. In trying to show the necessity for this system of farming, we have hinted that it will pay; everything necessary pays, and if it be admitted to be a necessity on most farms, then it must pay better than any other system. Will it pay to bring stock to perfection, and turn them out in good condition to the fairs? Then such cannot be done on medium quality of land without feeding materials grown on the farm. Will it pay to have a variety of produce in the market, even though that should be small? Then the judicious system of cropping produces that. Much of the disappointment to farmers arises from the necessity of being compelled to sell their stock in a poor condition; and this is owing as much to their injudicious method of feeding as to the want of capital. If there be a bad system of tillage on the farm, there will be a lack of feeding materials, and the stock is either starved or half-fed, and the result is always small prices. I have observed when small farmers are taking one-acre, and always making large quantities of manure to raise crops of their farms, that most generally these men are prosperous. On small farms no other system will pay than mixed husbandry. The northern farmers are compelled from the poverty of the soil, as well as from long custom, to carry out this system, and it is generally admitted by all parties who know Ulster that the farmers there are much more independent and have more money and capital than in some of the other more favoured provinces. Besides the emigration from Ulster has not been anything equal to that from the other provinces; and this arises from the variety of employment for the labouring classes, and the remunerative wages they get for their work. Some time ago in the south of Ireland there were twenty labourers for one farmer; now it is twenty farmers for one labourer. Many causes may have been at work to produce this change, but one cause is patent—want of regular employment and fair wages all the year round. It may be objected to the mixed system of husbandry, labourers cannot now be obtained; but if machinery were introduced more largely, and a good pair of horses could be kept at work during the entire year, under a skilful man, a large amount of cropping could be carried out with comparatively few labourers. The scarcity of labour necessitates the introduction of machinery, and in a very short time farmers will save as much from hand labour as would purchase the necessary machines. Thus by machinery in part and doing as much as possible by horse

work, enough of cropping could be done on most farms, sufficient for all purposes of feeding, rearing, and some to sell. By skilful management much labour might be saved which is now on many farms expended for naught. Seasonable work seldom or ever expends labour, and one reason why tillage will not pay many is the consequence of the unreasonableness of it. I have seen the ploughing commenced on a farm of considerable dimensions when it was nearly the time to sow, and thus every species of crop was shunted back to meet the farmer's convenience; bad crops, as might be expected, was the result, and the farmer was always saying tillage will not pay. Another reason why it does not pay, many have the system of employing labourers, instead of keeping a few constant men at work, giving them comfortable little houses and gardens, so that they may take a deeper interest in their employer's work; a number of workers are engaged to put in and take out the crops at high wages, and then dismissed. This system is bad, and always disappoints. A writer on mixed husbandry asks the question, Will it pay to raise from 30 to 60 tons of turnips to the acre? Why, even to sell an acre of 40 tons at 10d. per cwt, would amount to the sum of £33, and all the other crops if properly grown would pay in proportion; but used for stall feeding and rearing stock they pay much more, as the manure is very valuable for the land. The consumption of a large portion of crops upon the farm is always wise, as it leaves the manure behind; the land requires to be stall-fed as well as the cattle in order to pay, and the cleaner it is kept with good feeding the better the pay. Unskilful husbandry will not pay, but we affirm without fear of contradiction, and our opinion is founded upon the experience of more competent men, that mixed husbandry, unless on very rich pasture, is the best farming in order to pay both farmer and labourer. It would be unwise to say what proportion of the farm should be tilled, as that depends very much upon the nature of the soil, drainage, markets, &c.; but the system I advocate must be guided by experience. I know the popular motto in agriculture at the present time is "Till little and graze all," but grazing all on small or medium sized farms would not pay. The necessities of agriculture as a branch of industry, the clear tendencies of economised science, and the growing education of many farmers will lead them to see that mixed husbandry is not only profitable, but required. Instead of driving away the people from the country, we want to establish branches of industry to entice them to stay; and instead of having merely one resource out of which to draw the revenue, the farmer, we consider, will be richer and more independent to have many resources. Whatever tends to industry tends to wealth and comfort, and this system, if properly carried out, will have that effect.

Thus then we say—

Mixed husbandry is the thing that should be—
Not too much, nor too little, but all to agree,
The farm well divided by labour and skill
Looks rich in its pastures, with no weeds to kill.

Emigration has ceased, for the men are at work,
And the farmer is active, and able to talk
About his cattle, pigs, sheep, the best of good stock,
All fed on produce, with a little salt rock.

The markets have risen, and he has something to spare
To catch the good penny and go the fare.
He buys some of clean stock, on his turnips to feed,
And says to himself, I will not be in need.

My neighbours may laugh. Oh, it's all very well;
But with mixed husbandry I am sure to excel.
These cattle, well fed to the first week in May,
In Dublin's good market are quite sure to pay.

Let all who object to this system first try,
For once in their life, and not be too shy,
By labour and skill they are sure to outrun
The timid in life, who are still overcome.

"Be men," said the general; "we'll fight it right out,
By gun and good bayonet we'll drive them all out."
By spade, plough, and harrow, the farmer should try
What benefit he'll have in his mixed husbandry.

THE GAME LAWS.

At the last meeting of the Devon Central Chamber of Agriculture, at Newton Abbot, Mr. C. J. Wade, the president, read the following paper :

Game and the Game Laws are questions occupying the attention of not only the landlord and tenant, but the whole community, and they will be found, on a careful and thorough examination, deservedly to do so. Chambers of Commerce, as well as Chambers of Agriculture, should take up the subject. It has antiquity on its side, and is a relic of the "good old days," and the numerous and various Acts which have been passed relating to it would, if collected, form a large volume, and some of them would be considered as curious specimens of a bygone age. About the year 1390, in the thirteenth year of Richard II., we find an Act relating to "such persons as should not have or keep any greyhounds hound, or other dog to hunt, and should not use fyrcles, keps, nets, hare-pipes, cords, or other engines, to take or destroy hares, conies, or other gentleman's game." And subsequently in 1492, in the seventh year of Henry VII., an Act was passed "against taking *feavants* and *partridges*." In nearly every reign legislation took place, from "hare pipes" to "taking hares in the snow." The mere fact of so many statutes being from time to time passed conclusively shows systematic opposition to or dissatisfaction with the game laws. There appears to have been a spirit of unrest respecting them. It will be our duty on the present occasion to consider, without prejudice on the one hand, or partiality on the other, some of the results of the game laws, and of the repugnance to them. We hear it said with regard to game—"that a merciful Creator" sent game as well for the poor as for the rich. How many are satisfied with this statement, without considering that the observation applies to all God's gifts! and how comes it, that so many persons are to be found, who are called respectable, and yet sympathise with the detected poacher? and these same persons, or of that class, do not hesitate to purchase game which may have been surreptitiously killed? and yet they would feel horrified at the mere thought of purchasing goods obtained contrary to and in breach of the laws? The fact that such sympathy does exist cannot be denied, and how few there are who take the trouble to inquire *why* it is so. By the common law, which, in this respect, is consistent with, and the exponent of, the natural law, tame animals were the subject-matter of property, and a man could bring his action in respect thereof. But wild animals were not so considered, and no person could have property therein unless they were tamed or reclaimed by him. Hence it appears that by the common law every man had an equal right to such creatures as were not naturally under the power of man, and that the mere capture or seizure created a property in them. The common law being as I have stated, it is clear that the whole of the laws for the preservation of game now in force, or which have been in past ages, are the creatures of statute, and it is because these Acts are looked on with disfavour, not merely by the poacher, but by his sympathisers, that the notion has become prevalent that there is no moral offence in their breach, forgetting that, were each individual to break every law which he disapproved, or deemed to be oppressive or unjust, there would soon be produced chaotic confusion in every community. If laws are bad, we ought to endeavour, by every legitimate mode, to get them altered, but, as good citizens, we are bound to obey them so long as they continue. By the present statute law "all game belongs to the tenant or occupier unless the landlord has expressly reserved the right thereto," and in further considering the subject we may dismiss, to a great extent, although not entirely, those cases where the tenant or occupier has the right to the game: although we may dismiss it to a great extent, still there is the question *where* game is excessively preserved so as to induce a breach of the law. The cases where it is reserved, and preserved in excess, either by the landlord or his lessee, are those cases which affect, not only the tenant by the destruction of, and injury to, his crops, but also the general public by the withdrawal from taxation, local and imperial,

of the value of the crops so destroyed or injured. It is an anomaly, and a gross injustice, that if the tenant or occupier has the game, or the right to kill the game, he is taxed locally and imperially; but if his landlord reserves such right and keeps it himself, or lets it to another person other than the tenant of the land, there is a withdrawal from all taxation, local and imperial. This directly affects, not merely the landlord and the tenant, but the public also. It is the class where there is excess of game kept by the landlord or by his tenant which affects the tenant of the land; he is debarred from expending as much as he would otherwise do, and in these days of progress and agricultural improvement, *he is bound to do, if he keeps his ground, because he does not know "if he shall reap as well as sow."* It is to this class (of excessive preservation) also we are indebted for "the keeper;" and do not for one moment think I am going to condemn this class absolutely, for I have known some as good and honest men amongst them as in any other class of her Majesty's subjects. And I have known and heard of some quite different—men who, by the temptations held out to them, have sold and disposed of that game which they were paid to preserve; and if a keeper will not hesitate to sell the game, he will not be over-scrupulous in trying to place the blame on others; and the tenant is made to bear the burden of the keeper's default. There is also another evil (and I have known cases of this class too), where a tenant has destroyed the young rabbits, thus touching the keeper's perquisite, and so sure as he does this the quiet whispering to the lord takes place, which is destructive of that confidence which should exist between him and his tenant. If the rabbits in every case were to be allowed to the tenant, and no other game kept to excess, I fully believe that the landlords would have plenty of true and genuine sport, and there would be a better feeling existing; there would be no withdrawal from taxation; offences against the Game Laws would be few; the trespass on the tenant's land would be less; the tenant would be proud in welcoming his landlord to a good day's sport; and the sympathy with the poacher would cease. We look on the agrarian crimes in Ireland with horror, and count the murders committed by the assassin; and yet we do not count the murders and murderous attacks in England; and what is the cause of the same? I fear that drink, and the false opinion I have referred to, and the sympathy with the poacher, and the temptation of excessive preservation of game, are amongst the chief causes. There are those (and I regret to have read the other day the name of a clergyman amongst the number) who say if landlords were not to have the game and sporting, they would leave their estates and rush into towns and to the Continent. I think this is a low estimate of the landlords of Great Britain; they, as a class, are ready to perform, and do perform, the duties as well as enjoy the rights of property, and I hope the day is far distant when we shall have to look on the landlords as an absentee class. They are quite alive to the truth that property is for the benefit of a nation, and the schools and acts and works of kindness and charity, all helped on and aided by landlords, bear ample testimony to my assertion, and to the contradiction of the threat I have referred to having any base. There are also those who say, "Let there be a valuation of the injury done." To this I make answer, it is almost impossible to tell the daily consumption of rabbits. We can appreciate the loss of the corn crop, but that is a part, and part only; the grass and seeds, and clover and caver cannot be measured or valued, and there is the loss or withdrawal from taxation of the amount consumed, and the grave and serious fact that any continued annual valuation could and would only be the source of irritation between the landlord and the tenant. I said I read with regret that a clergyman should have stated or hinted at landlords leaving the country and the homes of their ancestors. By so doing, indirectly, he advocates the keeping up the present system. If, however, we were to examine how much crime exists in this country which may be traced to poaching, which produces drink and leads to other excesses; and if a man is out poaching and gets no game, something else must supply its place—drink

must be had, and frequently a family precariously supported, for poachers as a class do not make the best labourers; and when a man once enters a gaol (and how many owe it to this cause!) the first step is taken, and the ruin of the whole family too frequently follows. Once accustom a man to a breach of the laws, and how can he define or determine the line of difference between a small crime and a crime of the deepest dye? In agricultural parishes, I will ask, what influence have the game-laws and the over-preservation of game had on the necessity for rural police? And how often have we known the poor-rates burthened from the same cause? Some gentlemen would now perhaps inform them how much they had individually suffered. For his own part he knew instances where parties had been turned out of house and home through this very over-preservation of game. In one case an action for slander was instituted, and this slander was through something whispered by the tenant to the lessee of a noble house; the farmer was immediately turned out of house and home; but fortunately, by a jury of his own country he was enabled to get heavy damages, and so he was partly recompensed for the injury done him by this ejectment. No doubt they could supplement these instances from their own personal experience—though, perhaps, it might be hardly prudent for some of them to do so. As to the partridges and pheasants, he did not believe they did any material injury to the farmers, except when they were preserved to such an extent that they might be killed by hundreds in a day (Hear, hear). Then of course the landlord compensated the farmer, or at all events he ought to do so (applause). But as to the ground game, unless the rabbits were kept down day by day they would become a perfect scourge to the farmer (Hear, hear). He thought that some plan or scheme should be devised to give the landlord a good legitimate day's sport: he did not call it sport when you drove game up in a corner, and then had loaded guns handed you so as to fire away as fast as possible. That was not the sport of a gentleman: let them kill the game when they could catch it (Hear, hear). As to what he had stated in his paper, he could support all he had said by facts (Hear, hear). He believed the day was not far distant when landlord and tenant would come together on better terms, and if the landlord had game on an estate he would let the tenant have the first right. If he let the game to a stranger, he should pay taxes, local or imperial; and if he (Mr. Wade) was asked how to levy those taxes, he would say the amount of taxes should be the value of the injury done. That would stop over-preserving (Hear, hear). He had been rather careful on this question because it was a touchy subject.

Mr. G. STOOKE did not disagree with Mr. Wade's paper, but he had no sympathy with those who went in for unconditional and absolute abolition of the game laws. If he was to be a sufferer, though he did not say he was one, and if they were to look on over-preservation as a nuisance, he would rather see the landowner reap the benefit of the tenant's injury than see a lot of idlers let loose on the country with no restrictions on them (Hear, hear). Many people, he thought, went in for the total abolition of the game laws because they thought there would be no penalty then; but they must remember that Dick, Tom, and Harry might then go over the farmers' land with impunity. He did not agree with that; but he thought there was a measure which every chamber of agriculture should advocate, and with which the country at large would sympathize, and it was this—that game and rabbits should be regarded in the eye of the law as the property of the occupier, and then an understanding might be come to by the owner and occupier. It was true that the landlord would, to some extent, be able to dictate terms to the tenant, but then, in return, the tenant would be able to say on what terms he would let the game back again to the landlord. They would then be able to make up in some measure for the damage done by the game, and at the same time tenants generally would be proud to give their landlords a good day's sport. If there was a proper feeling the tenant would feel it a pleasure to relet the shooting of the game on the property which he occupied. That would, he thought, "cut the knot;" for if the tenant became aggrieved it could only be by some of the conditions on which he took the farm being broken. He believed that if a tenant was injured by the game he should have some voice in the matter (applause), and all the power should not be in the hands of the landlord (Hear, hear). There then could be a proper understanding as to the shooting, and the

tenant would be able to have some voice in saying who should be the lessee (Hear, hear). In some instances the lessees were really gentlemen. He knew one lessee who never shot the rabbits himself, but left them to the tenant, and he never said anything if the tenant had an occasional day's shooting, and, kept within moderate bounds. On the other hand, he knew one property on which was a lessee, and on that property all the game seemed to be "farmed." He could not say that he knew for certain that the game was all turned into hard cash, but everything was "kept close," and a tenant would not like to shoot even a rabbit, nor would the lessee like to see him either, except, perhaps, in the month of February, the tenant might be allowed to do so. He thought there ought not to be a third party like this coming in between landlord and tenant. A tenant ought to be able to say whether such a party should be a lessee or not. This idea might take some gentlemen by surprise, but in his opinion they ought to have what was straightforward plain dealing and fair play. It should not be all on one side. A tenant should certainly have his privilege, and he did not think any right-minded landlord would refuse it. Some chambers of agriculture were going in for the total abolition of the game laws. He did not think this would meet with general approbation, but he believed that a very great number would fall in with the scheme he had mentioned if it was generally known. He would also try to assimilate the game laws to the dog tax; he would reduce the cost of a certificate to a mere nominal sum, and call on every man who carried a gun to pay say 10s. a-year, and that would deter many a poacher who now slinks about with a gun, and he believed the revenue would be a gainer by this (Hear, hear).

Mr. J. CREEK agreed with much that had fallen from the previous speaker. He thought the game question laid in a nutshell. He thought that every person who kept a large stock of game should pay compensation to the tenant for all injury done, and he felt that if the compensation was paid the tenant had nothing more to complain of. But then, on the other hand, there would be a complaint from an outsider, and that would be the consumer, who would say there was so much consumed by the game, which would otherwise be brought into the market. He felt that if they legislated severely on the game question it would be the means of driving the game altogether out of the country, and that, as an old sportsman, he should not like to see. He thought that if compensation was made, and there was a clause in the lease giving the tenant power to call in a valuer who should say the amount the tenant had suffered from the game, and that the landlord should pay this amount, then he thought the matter as between the landlord and tenant would be at an end. The tenant-farmer ought to have the compensation which he deserved and which he ought to have a right to demand. As to the question of driving the landlords out of the country, there was something in that. They might depend upon it that if the large landowners of England had not an inducement to come and reside among their tenants it would be a very sad day for the tenants. A landowner might be in town or on the Continent during the summer months, but when September came the landlords came to their homes and remained there until January. Their coming to their country residences and spending their money was a very great benefit to the neighbourhood in which they resided. He should be sorry to see the tenantry of England drive the game question so hard as to drive the landlords away from them. He agreed with what Mr. Stooke said as to the tax on guns, for he believed that if the tax was put on the gun instead of on the certificate it might be the means to some extent of obviating the present difficulty they had to contend with and the amount of expenses they had to meet by the over-preservation of game. On the other hand he thought—and he was sorry it did not come from the chairman—it was to be regretted that there was no law of trespass except a man was in pursuit of game. He should like to see some law of trespass whereby if a man was found on your ground you could have the power of removing him and so prevent parties from going over your land just as they liked. That would do a great deal to put down poaching. He had seen that some advocated the keeping of game just the same as you would barn-door fowls, but he was not an advocate for that. This question of the game laws was a very large one no doubt, but he thought the tenant-farmers had it in their own hands. It was for them to say whether they would take a farm on a lease having the game-reservation clause in it. If they only

stuck together they could dictate terms to the landlords, and he thought they had the remedy in their own hands if they only liked to use it. He did not think they should want to have House-of-Commons legislation on the matter, but as Englishmen they should assert their right, and he did not think that if they came honestly before the landlords that right would be refused. In conclusion he thought that as the chairman had read so excellent a paper and gone so far into the question—though not so far as he should like to have seen, for there was a lot behind—he deserved their best thanks for the great trouble he had taken and for his admirable paper.

Mr. NORTHGOTT (Christow) said he felt very strongly on this subject, and might have what were called extreme opinions. He felt that shooting was not in accordance with the age ("No, no," and "nonsense"). On looking in history he saw that the origin of shooting was in a most barbarous age, when it was necessary for the savages to use bow and arrows or some weapons to kill wild animals for subsistence. But as soon as the country became more populous it was found necessary to till the soil, and the weapons were laid aside. We were now in a commercial stage, and what did they want of shooting now? He held that the agriculturists were entrusted with a very great mission, and that was to grow food for the people, and if they did not do it some others would. At the time the Free-trade measure was passed it was said to farmers, "Oh, you needn't grow anything more," but they found it necessary to grow more and more. But the game had done a great deal in destroying much of their produce, and he was of opinion that in the last dozen years the game-laws had ruined more produce than would have paid off the whole of the National Debt. There was of course a difference in the amount of injury done to different estates by the rabbits. He was on one estate where scarcely 5s. worth of damage was done by the rabbits. On the estate he was now occupying he had a four-acre field, and last year it was sown with wheat; he manured it well, and in about ten days the wheat came up, and it was no sooner up than the rabbits bit off every blade; when he thrashed that wheat the whole produce of the field was three bags and six pecks. The injury was not only the loss of the crop, but there was also the waste of the manure. He thought the tenants should have a safeguard for the outlay of their property of two years' rent. He then referred to a committee having been appointed to draw up a model lease and their failure in doing so, after which he went to the question of trapping rabbits. Some said they kept the rabbits down by employing a trapper, who got so much for each rabbit he trapped. It was ridiculous to say they kept them down by this means, for there were two parties interested in preventing their extermination. One was the man who caught the rabbits, and the other the man who sold them; if they killed all the rabbits their trade would be gone, and of course it was to their interest not to exterminate the rabbits. He protested against shooting because it was a sport that could not be enjoyed by all parties, and he thought that any sport should not be kept from the lower classes. As to what Mr. Creed had said about the tenant dictating to the landlord, that could not be carried out, for where there was one farm to let there were ten applicants. He urged that no one ought to be allowed to foster that which was so detrimental to the welfare of the general community as rabbits. Good farming could never be carried out unless a regular basis was laid down by which shooting should be ruled. He was in the position now where the game was rented, and he felt that it was a position in which no man should be put. He concluded by seconding the vote of thanks, which was carried by acclamation.

Mr. H. H. WATSON (Totnes) said he had been struck by the tendency of one or two of the speakers who had led them to believe that the land-owners would leave the country if the game was going to be destroyed. He could not help thinking that many of these fancies were imaginary, for he did not believe that the landlords were so unpatriotic, so selfish and unwise, as to think of such a thing for one moment. As to the injury that was done to the people of this country by the ravages of the game there could be no two opinions. It was thought by some that it was only a question between landlord and tenant, but it was very much larger than this. He believed that the tenant was not fairly compensated, nor would he ever be, for a surveyor who was called in could not give a fair estimate, for he could not tell to

what extent the crops had been damaged. It was very discouraging to a tenant, after he had laid out a lot of money, to find his crop destroyed and each succeeding crop injured. It would affect not only the farmer himself but also the landowner. The public generally had an interest in this question, inasmuch as they must be fed from the produce of the land. He was surprised to hear some gentlemen say the game-laws were inviolable. As to the plans that had been spoken of, he could not understand that either Mr. Creed's or Mr. Stookes' would be a remedy to the evil. He did not think that the game-laws should be entirely abolished, but he hardly knew where to stop; at all events he should not like to see the laws remain as at present.

Mr. SOWTON (Ipplepen) did not understand Mr. Stookes' plan, and did not see that Mr. Creed's would meet the requirements of the case. He was not in favour of the game-laws being done away with altogether. He thought, however, that the tenant should have the rabbits for himself, that he should be allowed to kill them any way and at any time he thought fit. Then he thought the great evil would be destroyed. As to partridges and pheasants, he did not think there was any very great ground for discontent about them. But he thought they ought to agitate for the rabbits becoming the property of the occupier, and then their crops would not be destroyed. He thought that if they went in for extreme measures they would not get anything, but if they went to work in moderation they would get all they required. As to the lease, what was the use of a farmer dictating to the landlord? The landlord would say, "I must have the game," and if the tenant demurred at this, the landlord could say, "If you don't like it, twenty others will have it." He could not see any other way of meeting the case than that which he had stated.

Mr. STOOKES wished to give a word in explanation. Mr. Sowton had said he was astonished at his scheme, and could not understand it, and then he went on to say that the rabbits should belong to the occupier. His (Mr. Stookes') scheme was just this, only he went in for a larger slice. He only asked that Chambers of Agriculture should advocate this, and that the law should recognise the rabbits as being the tenant's. He did not mean to take solely what the landlord said, but let it become law, and then landlord and tenant could come to terms afterwards. Unless they had it made law some difference would be sure to arise.

Mr. COULTON (Paignton) agreed with nearly all that had been said by Mr. Sowton. As far as hares, partridges, and pheasants went, he did not think they did much harm in this county to the crops. He thought, however, that the rabbits should be entirely under the control of the tenant, who should have the power to trap, ferret, and destroy them at any time. He thought that where hares and winged game did £1 worth of damage in the county, £20 damage was done by the rabbits. Every right-minded landlord who went over a farm, and saw the injury done by rabbits, must feel that it was not right to allow such a state of things to exist. For his own part, his late landlord, Col. Buller, and his present landlord, Lord Churston, always called the keepers to account if they saw many rabbits on the farms. The rabbits generally did most damage on the poorer parts of the land, where the tenant had to expend most money, and they soon took the rent out of the crops. The great evil was where the game tenant got all the rabbits, and that was what the tenant farmers ought to prevent if they could. Then, as to the keepers, he should like to see the tenant trusted more and the keeper less—there should be greater confidence between landlord and tenant. He had seen, and of course there were, good honest gamekeepers, but some of them were as great scoundrels as ever existed. As to the game-laws, he should not wish them to be altogether done away with. He referred to the speeches of Lord Morley and Sir M. Lopes at Plymouth, and regretted to see that the landlords were not present to-day, for it was a question which materially affected them as well as the tenants. He concluded by proposing: "That this Chamber is of opinion that the tenant should have the full power to trap, net, or destroy the rabbits at any time." This, he thought, would meet the case.

Mr. W. RENDRELL (Netherton) would be sorry to see the law deprive the good old English landlord of his sport. If there was a proper confidence between landlord and tenant, they would, instead of having less game, have more. The great complaint was where the third man stepped in. The rabbits were kept at the expense of the tenant, and carried to

market to the profit of the third man. That was the galling part of it. It was not the game generally, he thought, that did any great damage, but only the rabbits. The total abolition of the game laws would not, in his opinion, benefit the farmers, nor did he agree with Mr. Stocker's plan to take the taxes off and make them less than at present. It would be taking it from the rich and putting it on the poor man.

It was then suggested by the CHAIRMAN that this meeting should be adjourned to the Totnes meeting, which would take place on the first Tuesday in January, when it would be discussed by a large assembly, who would also be brought together to speak on the Turnpike Question.

Mr. WARSON, after saying that he thought the total abolition of the game laws would be the result, though he did not quite advocate it, moved the adjournment of the meeting.

Mr. J. H. BROWSE (Paignton) agreed that the tenant should have the right to destroy the rabbits, but he did not

think there should be a total abolition of the game laws. He thought that any ill-feeling that existed between landlord and tenant was caused by the third person stepping in. As to the game shops in towns, they were no doubt supplied by gamekeepers and poachers. They ought to do away with these two parties; and to get rid of the poacher, he suggested that everyone carrying a gun should have to get a certificate costing him £3, and to enable him to kill game he should have a second £3 certificate. This should apply to all except tenants of farms, and then it would put a stop to poachers.

Mr. POLLARD (Paignton), thought the landlords should take care to let the farms only to men of honour, and place the game entirely in their hands. Then the tenants would always be proud to provide their landlords with a day's sport.

The CHAIRMAN then acknowledged the vote of thanks awarded to him, after which it was agreed to adjourn the meeting, as proposed, at Totnes.

FARM LEASES.

At a recent meeting of the Maidstone Farmers' Club, Mr. Thomas Bridgland, jun., in the chair, the subject of discussion was Farm Leases, and the circular stated that the subject had been brought before the notice of the committee by the Chairman, at the request of a large landed proprietor in this part of the county, who had expressed a wish that the Club should endeavour to draw up the clauses of a farm agreement, which would be fair both to landlord and tenant.

Mr. CRITTENDEN said the subject which he had the honour of bringing before them for consideration was one of such very great importance, that he must apologise for taking upon himself the duty of introducing it. It came before them under very impartial auspices, having been pressed upon their attention by a large landowner in the neighbourhood. But independent of that, many members of the club had been for some time anxious of discussing the subject with a view of calling to it the attention of owners as well as occupiers of land and to elicit, and they hoped, to obtain considerable benefit from the various and opposing opinions which undoubtedly existed upon it, and not from any wish on their part or his of recommending any specific form to be adopted, far less of fettering the free rights of the owner of the soil of doing what he likes with his own; but if in so doing he wishes to improve his estate, to act fairly to the tenant, and contribute his item to the general advancement of agriculture, the terms of tenure and cultivation must be fully and fairly considered. The first relation of landlord and tenant was one of buyer and seller. The principal item of the bargain, as all would understand, would be the rent, and it became the duty, as well as the interest, of the landlord, that question being settled, to see how far, while securing himself from injury, he could give to the tenant full and fair scope for the exercise of his ability, so that he could obtain from the land the greatest possible amount of produce; and not, perhaps, as is too often the case, tying him up to farm upon some particular system which is either out of date, ill-adapted to the position of the farm, to the requirements of the market, or to that course which the man himself may be best adapted to carry out successfully. They were all aware that certain methods were adapted to certain lands, and individuals also had peculiar methods which in their hands best tended to success. The general security which tenants have had for some time has been the character of the large landowners of this country, which has certainly stood very high, and men have farmed under them with confidence and satisfaction for many years. Still, changes, in order to keep pace with the times, involved a more expensive, a more energetic system of cultivation, and the farmer did not now look to his reward this year or the next, but to a distant period, probably spread over years. In that case, however sure a tenant may be of the good faith of his landlord, something may intervene. Death, or a change of ownership, or a change of stewardship, or some unforeseen event, may deprive him of his expected and just reward. Many as tenants-at-will had occupied under their landlords and their fathers before them, and that indisposed them to say anything about the matter. Others felt it not to

be prudent, for the landlord might very possibly say, "What you and your family have occupied under me so many years, and begin to doubt my word? Have you lost confidence in my sense of honour? If that is the case, some one else must have the farm." Let us suppose that the landlord, valuing for himself a reasonable independence and protection from loss, thinks he might extend it to his tenant, and replies, "Very well, I will give you a lease. I am going to London to-morrow, and I will see my lawyer on the matter." He went to London, and the lawyer got down from his dusty shelves a cut and dried form, and brought to bear such an amount of agricultural knowledge as he might have picked up in his walks through Lincoln's-inn-fields or the Temple gardens and drew up a document; and could it be a matter of surprise if it should prove very good law but very poor farming. In this clauses are introduced, which, if fully enforced, are ill-adapted to the agriculture of the present day, so that the desired result is as far off as ever. There was, however, this saving clause, and it was a blessed one, that those stipulations were rarely looked after and enforced. In nineteen cases out of twenty if they were enforced, they would be a serious injury to the industrious and praiseworthy tenant. But although those clauses were not enforced the stipulations were ever before the man's eyes, and were one of those little checks to the advancement of agriculture which all were supposed to wish to have removed. On the other hand, it was only reasonable that in giving up his land the owner should wish to retain a little power over it. To prevent it from being injured by bad farming there should be such restrictions as would protect it. Penalties and restrictions bristled in some leases, but that they were any check against injury he doubted; they were a far greater check against improvement and progress. They could endorse that from their own experience. Land let to a good farmer was certain to be improved and returned to the owner in a more valuable condition, and all the laws by which an agreement might be fenced round would not prevent a bad farmer from deteriorating his holding. This, of course, involved the necessity of inquiring into the character of the would-be tenant, and in this there was little difficulty. A large proportion came from the immediate neighbourhood, but where the applicant came from a distance there was little trouble in inquiring into his antecedents. The leases ought to be drawn with as few limits as possible. Men who wished for leases were generally hopeful, earnest, energetic men, who were not quite satisfied with the old way of joggling on, but hoped to see something better than has been done, and were willing to expend both money and labour. Whereas the expenditure of a man who feels that he may have to leave his farm at six months' notice must always have a view to immediate results. He will not, and cannot, wisely lay his plans involving outlay and labour far into the future; thus permanent and urgent improvements must be discarded, and he is too often haunted rightly or wrongly, by the bugbear of having his rent raised over his head as the result of his own improvements. With regard to the terms of the lease, he would recommend, as he said at first, no specific form, only to press the principle that

security of tenure should be given to the tenant as well as freedom of action, freedom to introduce or originate any better system of cultivation than that of his neighbour if he can. The term should be for 14 or 21 years. Seven or ten years might possibly answer the purpose of the agreeing parties, but any term less than seven years was little better than a yearly tenancy. Many of the clauses of the lease must be what they are now. The usual guarantee of rent and taxes by the tenant, the timber not cut, underwood not to be grubbed, nor the grass land broken up without consent. It might be desirable—he did not say that it was—that in this part of the county there should be a certain acreage of hops stipulated for, but in that case the tenant ought to have reserved to him the right to grub and plant at will. All moneys received for hay, straw, and roots should be expended on dung, artificial manure and oilcake, and that the tenant should quit the farm on the same terms as those on which he enters. But, above all, what to plough and what to sow, what was to be the system of cultivation, ought to be left to the judgment of the tenant, so long as there was no cause for dispute. If dispute should arise, it ought to be settled by two independent parties or their umpire, and if they found that the man was not farming in a good and husbandlike manner, then and then only should he be compelled, on pain of forfeiture of the lease, to manage the land on a fixed system named in the lease as that to be pursued during the last year or two of the term. Although the tenant ought to be allowed his full swing during the greater part of his tenure, it was necessary that the land should be left at the end of the lease in such a condition as to secure the incoming tenant from injury. They now came to a term in the lease which if they were to talk till doomsday they would not quite get settled. It was generally expressed in this way, “the landlord reserving to himself the right of sporting over his farm.” And a very good right he had to reserve it if he chose, and very few tenants would object to it, provided the owner himself shoots. But if he was going to turn his land, which ought to be growing food for the people, into a poultry yard, then he contended it was a serious injury to the tenant, and contrary to the spirit of the age. It was no more justifiable than would be the re-introduction of the barbarous boar hunt of their Norman ancestors. A landlord, benefiting largely by the immense strides of arts and commerce, and civilisation generally, must be prepared to make some concessions, and his love of sport must be kept within the bounds of moderation. There was plenty of shooting, which no farmer would object to, and which, he believed, every tenant farmer liked to see, but when 20 or 30 keepers were placed on a farm and pheasants ran about as tame as their own cocks and hens then it was that they protested. He ventured to speak plainly, for it was quite as well that landlords should understand their opinions upon the question. They said let them shoot, let them sport, but let them do it like sportsmen and gentlemen, and they would lend them a helping hand and preserve all the game they could. That was a matter which should be settled, as part of the original agreement, and not left to the discretion of either party, and should be fully borne in mind when considering the rent. Then there was the question of rabbits. They heard something about them lately. His opinion was that they should be subject to the same laws as the rats. He would keep them under, not exterminate them, and the tenant ought to be the party to deal with them. He could only express his regret that they should in these days hear of some glaring cases where the property of the tenant was destroyed through the heedlessness of the landlord. This naturally caused some dissatisfaction, which he hoped might be removed through the good sense and good feeling of both parties. He did not look to the remedy which some people were advocating, and which was now being promoted by the Scottish Chamber of Agriculture, that of legislation on the subject of ground game. With regard to the clause against sub-letting, Mr. Chittenden pointed out that it required a little relaxing, especially under circumstances of ill-health or death, and said when a tenant was unable to carry on his farm, he ought to be able to dispose of his unexpired lease. Although a landlord in case of death, might not forget the rightful claim of the widow and orphans, they ought not to take that as a favour which was their right. With regard to culture, he said, some leases provided that the tenant should not grow two white straw crops in succession, a restriction decidedly absurd and unreasonable. They had lately some of them seen Mr. Lawes’

farm, where wheat had been grown successively for 16 years. He did not pretend to say that they could do that as farmers, he only knew that it had been done, and that there was a possibility of doing a great deal more in growing white crops than had ever been dreamt of. On another piece of land Mr. Lawes had grown nine crops of wheat in 14 years, and if Mr. Lawes had done this, why might not they all hope to do it? He, therefore said, “wipe out all restrictions regarding white straw crops.” The land would speak in very pocket-touching terms to the tenant if he attempt to over-crop too closely in proportion to the skill and liberality of his management. In conclusion Mr. Chittenden said he would venture to press upon landlords—he was sorry they were not there that evening—to give leases, for he was sure in the majority of cases their property would be materially benefited; and to the tenants he would say “strive hard, and never rest till you get them, and you will have a security and comfort which you have never felt before.” The tenant would then have opportunity of carrying out schemes of improvement which would be the natural result of more leisurely reflection, and would benefit the state and his own private interests. And while pressing the general adoption of leases upon their consideration, he need scarcely remind them that when Scotland and Norfolk farmers took their first famous steps in improved cultivation, leases were demanded, and were granted as the sole secure basis of action. Obtain, then, these leases, he said, but make their conditions more free; strike off the fetters that have so long tied the thoughts and hands of the farmers, and although it may not be even then all serene, it will conduce to the prosperity of all parties concerned, and will help on a progressive and a more largely-producing system of agriculture. He might remind them of what, perhaps, they were all too well aware, that the farmer was very hardly pressed by the foreign producer, and that in many respects he was at a considerable disadvantage. He had high rents, high taxation, and his expenses were large. He had sufficient impediments already without any further being placed in his way. He thought, therefore, they might ask fairly for security of tenure, and such freedom of action that the farmer might enter with heart and energy, and let them hope with success, into that competition which he must encounter.

THE SECRETARY then read a letter from Sir Edmund Filmer expressing his desire that the connection between landlord and tenant might be established on a fair basis. He also said that he was constantly in the habit of giving leases himself. He should have been present, but an unavoidable engagement prevented his doing so.

The following letter had been also received from Mr. Elvy:—

“To the Chairman of the Maidstone Farmers’ Club.

“Dear Sir,—As the oldest member of the club, being from age unable to attend, I have put down the heads of a lease I should be willing to take or to give. I believe the shorter and plainer leases are drawn the better. Farmers may have brains enough to farm, but none but lawyers can understand the present leases—that is if they be meant to be understood.

“Yours very obediently,

“Bowhill, 18th Nov., 1869.

“F. B. ELVY.

“Where a lease is not granted a yearly notice to quit should be given, not six months, which is unfair both to landlord and tenant. Whatever the term of the lease the following, I think, are fair terms:—No restrictions as to farming; the times will not allow this. Let the restrictions be a covenant to farm according to good husbandry. To be determined by referees at the end of the lease, or the landlord to have the power of calling on them before the expiration if any gross conduct should render it necessary. The premises to be put into good tenable repair by the landlord, the tenant afterwards keeping them so, on being allowed materials. No permanent pasture to be ploughed up or woods grubbed without consent of the landlord. All draining, or other improvements which require time to repay, to be done by the landlord, the tenant paying 5 per cent.; or, if done by the tenant, with the consent of the landlord, the moiety of the improvements not worked out to be paid for at the expiration of the term. The landlord, or his agents, to have the right to examine the state of the farm from time to time. Hay and straw, or dung, or other manures to be paid at market price; no half manures allowed. Wood, of course, valued to the stub. Timber and fruit trees preserved. Hares and rabbits the joint property of the land-

lord and tenant. Winged game, if desired, the sole property of the landlord. Rent, half-yearly if required. Tithes, poor's rate, &c., paid, as usual, by the tenant. The lease to be drawn in a plain intelligible style; no tautology, such as most leases contain, to render it impossible to understand them. If necessary let the charge be as much for short common sense."

Mr. HODGKIN said there could be no doubt whatever as to the importance of the subject. It had occupied the attention of the Committee of the Farmers' Club and the Council of the West Kent Chamber of Agriculture. There was no doubt whatever that a good lease was necessary for the protection of the tenant, and the progressive character of the age had been well illustrated by the letter which had been received from Sir Edmund Filmer. Any advance in the matter would be alike to the interest of landlord and tenant, and he was sure that it was only necessary for their requirements to be made known for the landlords to fall in with them. The question was, what did they want? The tenant had a right to ask for a free and fair user of the land, presuming the rent was paid, and that he should be able to make the most of his capital and labour, for in advancing his personal interest, as he said before, he was advancing at the same time the interest of his landlord. With regard to the term of the lease, he thought it should not be less than 14 to 21 years, so as to enable the tenant to make the utmost use of his capital. He thought that evening they should come to some practical result by forming themselves into a committee, so as to draw up a farm agreement "which would be fair to both landlord and tenant." There was one matter on which Mr. Chittenden, although he had treated the whole subject in a most admirable manner, had borne too tenderly—the subject of ground game. It was quite time that question was settled. The farmer was now in sharp competition with the foreigner, and anything that restricted his operations ought to be done away with. He thought they could not do better than send up a strong resolution to the Central Chamber of Agriculture, to the effect that the club seriously wished to record its opinion that the over-preservation of ground game should be put an end to by legislation. Mr. Hodgkin then pointed out that his crops in a certain district were eaten off by his neighbour's rabbits, and said nothing could justify his being placed in that position. He thought there was a criminality in the over-preservation of ground game, and that the tenant ought to be allowed to kill all the ground game he found on his own land.

The CHAIRMAN said he could not conceive how a man, who was in the happy position of farming his own land, could complain of anybody's game. If he was in that position, and any nobleman's rabbits or pheasants should come upon his land he should have them. He then called upon the members of the club to keep as strictly as they could to the point, that of farm leases.

Dr. MONCKTON said, he believed if a table were drawn up showing how many farms were held under leases, they would find out that the very best landlords in Great Britain granted the fewest number. Still that was no argument against claiming as a legal right what has hitherto been coded as a

friendly privilege. He quite agreed with Mr. Chittenden as to the absurdity of a large number of leases, and he gave an instance. He said in leases they ought to agree, and write down in fair common sense what they meant, so that they could understand it when it was written. But all this, he said, would of course, after all, depend upon arrangement. Upon the subject of growing two straw crops in succession, while he fully went with the experiments carried out by Mr. Lawes, where nine wheat crops had been grown in 14 years, he thought it was not a precedent to be adopted for their radical guidance in the construction of a lease. A note to the steward, where a man was desirous of carrying out a honest straightforward course in the management of his land, would be found generally sufficient. He protested against any broad and general rules being laid down in all cases. All permanent improvements, he said, ought to be carried out by the landlords, so that they should no longer have any questions of compensation. With regard to game, he humourously pointed out that pheasants were extremely scarce, and said if any one stood on Debting-hill and took in a radius of 10 miles, he did not think much damage could be said to be done there, and that would include a large game-preserving district.—(Mr. STONHAM: "I have had £100 damage done on 200 acres of land in one year.") In reply to Mr. Stonham, he would put a purely suppositions case. Supposing a farmer on 200 acres of land lost £100 by game and rabbits, and supposing he paid 10s. per acre less on account of the fore-known game, how much would he lose? (Hear, hear, and "That's it.") After all the lease should be the mere embodiment of what was accepted by business men as "the custom of the country."

Mr. STONHAM urged that "market" instead of "feed" price should be paid to the tenant for hay and straw on leaving his farm.

Mr. BUSS said that there should be a covenant in the lease that the landlord should find all the materials except straw, and do all the repairs, so that the tenant should not be subject to a claim for dilapidation.

Mr. WOOD pointed out that the generality of landlords were honourable and liberal to their tenants, when they could make direct application, but a second party frequently intervened in the shape of a steward or bailiff. In many districts the landlords let the shooting over the heads of the tenant to a comparative stranger, who sent down three or four keepers, and the land was stocked with game instead of sheep or oxen. He knew an instance in which a landlord had given power to a tenant to dispose of his lease on terms equitable to the tenant and satisfactory to himself.

Mr. CHITTENDEN replied. With regard to the leases, he said, sweep everything away that affects cultivation, and let everything, whether dilapidations or damages through the landlord having too much game, be referred to arbitration. He believed that all matters in dispute could be settled by two gentlemen competent to judge quite as fairly and quite as justly as if they wore the wig or the ermine.

A vote of thanks to Mr. Chittenden was carried, and the proceedings terminated.

THE SMITHFIELD CLUB SHOW.

(Concluded from our last.)

THE IMPLEMENT DEPARTMENT.

We have here to notice more fully the ingenious and simple arrangement shown by Messrs. Hornsby for throwing the cutting-knife of their reapers and mowers out of gear. In their self-delivery machines it is important of course for the man working them to have his hands free to guide the horses out at the ends, or to pull them up in the event of a casualty. And in the smaller machines, where the rake is used, it is equally important that his hands should be at liberty to work-off the sheaf at the right time, and to do this too, as it generally requires to be done, simultaneously with throwing the

knife out of gear for turning a corner or backing for the purpose of re-starting in the right position. Being able to do this with the foot, therefore, and much easier too than it has hitherto been done with a lever and the hand, is an arrangement which merits the greatest consideration by practical men. Supposing the knife is working, and it is necessary to throw it out of gear, all that the man working the machine needs to do is to kick the catch with his disengaged foot, and the required object is effected in an instant. And, again, supposing it is necessary to throw the work into gear, all he has to do is to place his foot on the lever to tighten the rod, when the catch drops into the eye previously referred to, and the cogs are held

as rigidly to their work as though they were a fixture. Any one who has driven a phaeton or waggonette with a hand-lever to affix a break will at once appreciate this arrangement, and, apart from the perfect convenience this is, as applied to reaping machines, it is not of less value for attaching to travelling carriages in hilly countries, when a break is necessary to keep the cross-bars off the horses' thighs or hocks. To complete the apparatus for reaping and mowing by horse-power, the Messrs. Hornsby have designed and completed a portable knife-grinding machine. This compact apparatus is fitted with a seat, and it can be worked with single or double treddle. With it there are rests for bearing and holding the knife when it is necessary to file it, or only requisite to "refresh" it with a stone. As the draught and cleanliness of cut greatly depend on the keenness of the knives, this portable grindstone and rest will prove a valuable auxiliary in the field when at a distance from the homestead. The Beverley Waggon Company have added a self-acting motion to their back-hand delivery machines. This is accomplished by a small cog-wheel, which is worked by the driving-wheel, so that at the end of every revolution of the smaller wheel the open "platform" is allowed to fall backwards, and the gathered corn is thrown off without any assistance from the rake, which can therefore be employed in gathering evenly the corn that is still being cut. Different sized wheels are provided for this purpose, so that the dropping of the platform may be more or less frequent, according to the thickness or other conditions of the crop. The accomplishment of this variation will be understood if the effect of different-sized wheels on a barrel of a corn-drill be called to mind. A small wheel comes round to act upon the lever more frequently, and a large wheel less often, and the distance the machine goes before it throws off each sheaf is regulated accordingly. Messrs. Pickaley, Sims and Co. exhibited their improved machine, which has the advantage of a set of driving cogs in each wheel, one of which is less numerous; and, therefore, by shifting the axle so as to throw one set out of gear and the other in gear, the knife is driven slower or more rapidly according as the crop of corn or grass may require a different speed. Messrs. Burgess and Key exhibited the various forms of their mowing and combined reaping and mowing machines, one of which was the original of "The Autobiography of an Old Screw," which appeared in the *Mark Lane Express* in September last, and wherein it was said it had been through ten harvests, and with a little care in regard to bolts and screws and a renewal of wearing parts, it was likely to go through as many more. Messrs. Howard have, we are informed, made several improvements in their reapers and mowers to obviate the vibration and friction which prevented their attaining their usual prominent position during the trials at Manchester. Messrs. Samuelson and Co., Banbury, had an effective show of their "Eclipse" and other reapers and mowers, both combined and self-delivery.

Of mills and food preparers generally, for single hand use or for grouping under a shaft for driving simultaneously by steam power, there was the usual display on several stands. There is but little new, however, in these machines which is of any practical importance. Messrs. Turner, of Ipswich, exhibited their usual stock; Messrs. Woods, Cockledge and Warner had one of each of their grinding and crushing mills, pulping apparatus, and soon, and an excellent vertical engine, at a low figure, for standing in a small space to work them. Messrs. Ransome, Sims, and Head had also their stock of elegantly-finished mills and machines for preparing corn and roots for the manglers of stables, stalls, and folds. In Gardener's turnip-cutter we found the Beverley Waggon Company had a decided improvement; for the revolving drum which carries the

knives was in the form of circular bars, between which, at the bottom of the hopper, are fixed small iron "pickers," or tongues. As these tongues project slightly beyond the bars (indeed, as far as they can be fixed so as not to catch the knives), the thinnest slice is caught by them, and cut into the required shreds, instead of passing through, as must be the case when only a plain surface for the roots to be pressed against is employed. On the gallery we found Messrs. Pickaley and Sims had a most efficient root-scraper, which shaves turnips and mangolds into tape-like shreds. For mixing with chaff for store stock, so that they may not be made too dainty with a few roots to eat straw or inferior hay, and thereby be simply induced to bellow all the day after they have gobbled up the few roots that can be spared for them—for this purpose, and now that there is some prospect of great efforts being made at home to grow sugar-beet to compete with the Indies in producing saccharine, this "shredder" is a machine which is likely to increase in importance and demand. Messrs. Richmond and Chandler were on the gallery with their large stand of mills and chaff-cutters, which are allowed "in the trade" to be unsurpassed for efficiency and durability of wearing parts. This character is attained from an additional pound, on an average, being spent in labour in drilling bearers and in planing spindles mouth-pieces, and so on. The application of springs, besides, to compress the "feed," instead of the old lever and weight, assures greater pressure when the hay or straw is thicker, while with the lever a thick "feed" tossed up the weight, and the pressure was thus made less at the very time when greater compactness was required to allow a clean and comparatively easy cut. The endless band with its cross-bars for carrying the "feed" forward, instead of its having to be dragged by the rollers near the mouth-piece, together with the long drawing cut of the knives used, make these machines as perfect in operation as can be desired. Mr. H. Bentall, of Heybridge, was also strong in his various preparing machinery, the plain and serviceable character of which is almost as well known all over England as it is in the county of Essex, in which it is made. Horse ploughs are "looking up," in favour and demand. Farmers, indeed, are coming back to a practical consideration of all things from a paying point of view. This consideration includes horse-ploughs. As it has been found that horses must still be used on the farm for general carrying-purposes, it is desired that they should not "eat their heads off," that they must be worked. It has also been found that tearing a steam-plough along at the rate of five miles an hour, from 8 to 12 inches deep, is not a safe plan for preparing a seed-bed, either for wheat in the autumn, or oats or barley in the spring. Curious examples of technical knowledge, as practised when a steam plough has been bought or hired, have been produced during the last few years. Farmers who would watch their men as cats watch mice, lest a greater depth than four inches should be reached for wheat when a horse plough was used, have no sooner obtained the command of steam power than they have rushed in where they previously feared to go, the result being an eight, ten, or twelve-inch seed bed, and scarcely any plants at all in the spring, and no crop worth cutting at harvest—in short, the steam ploughing produced a *death-bed*, instead of a seed-bed for the wheat. This may account in some measure for no steam plough being in the Hall during the late show. The success, too, of Pirie's three-wheel and two-furrow plough, as made by Messrs. Fowler and Co., Leeds, is proof positive that the use of the steam plough for a cereal crop is almost altogether abandoned. Two other ploughs on Pirie's principle are said to be in the field, and that the right to make the diagonal axle, wheels, and other

parts of this singular plough may possibly be contested in the law courts. In regard to one-horse ploughs we need only mention the names of such makers as the Howards, the Ransomes, the Hornsby, and Balls, for their iron ploughs are everywhere well known and practically appreciated according to their merits. Indeed, these ancient implements of husbandry have become so perfect under the hands of our modern agricultural engineers that it is now just a matter of the character of the work to be done, the quality of the wearing parts, and the price that need guide any one in selection. But Messrs. John Cooke and Co., of Lincoln, have recently produced a novelty in wood and iron, which has attracted a good deal of attention, not only of farmers but of other makers. This implement is as strong in the parts which take the strain of the draught when it is at work, as the beam and handle of an iron plough are at one stone more weight. This strength with lightness is obtained by affixing to a wooden beam a length of "angle" iron $3\frac{1}{2}$ inches by 3 in width. The thickness of the "angle" iron is regulated according to the work the plough is required to do. But the strength of $3\frac{1}{2}$ inches of iron one-eighth of an inch in thickness may be reckoned by an attempt to bend a narrow iron hoop sideways. We here, of course, confine our remarks to the strength and durability of a beam so constructed, for any form of mould-board and other arrangements can be fitted, and we have already allowed that work by ploughs, like the cutting part of reapers and mowers, is an accomplished fact, needing no further improvement. The whole matter has now, therefore, resolved itself into work to be done, first cost, and wear and tear of parts.

In screens and hand-winnowing machines there was nothing new, but Messrs. Garrett, the Ransomes, Peuney, of Lincoln, and Boby, had specimens of the rotating and oscillating screens, all of which are scarcely open to improvement for the purposes for which they were intended. The amut and atmospheric separating machine, however, of Messrs. Neil, Harrison, and Co., of 78, Aldermanbury, London, is a wonderful contrivance for a combination of economised space, and doing an extraordinary amount of work in dressing corn. The smuts are first rubbed to pieces in a cylinder, or any foulness which may have been produced during a long sea voyage is then rubbed loose, when corn and dust together pass into a box at the bottom of the machine, where a sieve is at work to receive stones. Through this box a draught of air is produced, which bodily conveys corn and dust to the top of the machine, over which all injurious matter is carried away, while heavy, medium, and light valueless grains fall upon sieves as they arrive into a wider space, and the air pressure on each grain is thereby diminished. This application of an artificially produced and confined draught of air to separating grain is by far the most efficient process yet introduced; for the specific gravity of a grain generally determines its comparative value, both as regards its nutritious character and purity. The most accurate screen or sieve cannot take out bulky light grains, when they do not exceed in size the ordinary measure of the bulk, but by causing them literally to be suspended in mid-air, and then carried by a cross-current over a sieve or box, where the draught grows uniformly less, must take from the bulk anything which it is desirable should not be there. This machine, however, is too expensive for farmers, except it be on very large occupations, but for mills and the granaries of merchants, it is a mechanical contrivance which performs its work in the most complete manner.

The seed stands were as large, as elaborately arranged, and as cleverly decorated with the more ornamental productions of each exhibitor as ever; and Messrs. Gibbs, Sutton, Carter, Wheeler, of Gloucester, King, of Cogges-

hall, Harrison and Sons, of Leicester, and others, had most effective displays, showing the advantages attendant on purity of seed for all kinds of agricultural crops.

THE SMITHFIELD CLUB SHOW.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—The return of the Smithfield Club Cattle Show suggests many pleasurable reminiscences to my mind, causing me to look back to what I always have considered its origin. I refer here to the practice of two patriotic individuals—Francis, Duke of Bedford, and Thomas William Coke, Esq., afterwards Earl of Leicester—of inviting agriculturists from every quarter of the civilized world to their annual sheephearings, for the avowed purpose of promoting the interests of agriculture by bringing together in social and harmonious intercourse a body of men hitherto isolated and almost useless to each other; but amongst whom in a collective capacity, by which mind is brought into contact with mind, the results of individual thought and experiment could be compared, a fund of useful information disseminated, and traditional errors in practice corrected. Those annual gatherings I had the pleasure of attending for many years, and both witnessed and partook of the almost lavish hospitality extended to five or six hundred persons, who, for three consecutive days, were invited to a sumptuous dinner, the noble host presiding. Men of all ranks, classes, and professions met there on equal terms, and men of science, particularly chemists, were special objects of attention, Mr. Coke being the first man of note who introduced those who professed it to the attention of the agricultural world. That science as applied to agriculture was in its infancy; but from the patronage of such men as the Duke of Bedford and Mr. Coke it soon assumed an importance which has ever since progressed, until it has become the leading agent in the cultivation of the land.

The Duke of Bedford unfortunately died in 1801, and his successor thought proper to discontinue the annual gatherings. The last was held the same year in which his brother died, and at this I happened to be present, and heard the expressions of regret that so useful an institution should be given up. Mr. Coke continued the meetings at Holkham as usual, until age and infirmity rendered the labour of preparing for and sustaining them too onerous to be continued. But the foundation was laid for that flood of light and knowledge which has since been brought to bear upon the practice of agriculture. We see the effects of this, in a greater or less extent, upon the whole body of agriculturists, not only at home but abroad; on the continents of Europe, America, and Australia (for this last must have such a character from its extent), and in every colony and country to which British intercourse extends. Now, whatever may have been the subsequent efforts of other men—and a powerful phalanx of scientific and practical men have sprung up and followed in the same steps—the movement certainly had its origin in those annual gatherings which took place on the domains and under the auspices of the Woburn and Holkham chieftains.

And what have been the ultimate results of these periodical invitations to men of science and practice from all parts of the world, uniting men of wealth, enterprise, and intelligence—men of all ranks and classes in society? We see the results in the universal movement of the agricultural world for the formation of kindred institutions, of both a local and a general character; in the establishment of Farmers' Clubs and of Agricultural Societies throughout the kingdom, by which mind is brought into contact with mind, which, like that of flint and steel, necessarily elicits sparks of intelligence, and knowledge is disseminated amongst a body of men who formerly led lives of isolation from the sources of information. We see these in the weekly reports of agricultural journals, of the papers read, and the discussions which follow on all subjects connected with agriculture and the cultivation of the soil. We see the results likewise in the multiplication of agricultural machines and implements, and in the rivalry of the makers of them, by which such is the perfection to which they have attained that manual labour in all its most onerous forms is reduced to a mere healthful exercise. We see these in the superior education of farmers, in the establishment of agricultural colleges where the youths are

instructed in both the theory and practice of their profession. Lastly, we see all these efforts culminate in the increased production of the soil, in the improvement of the types of both animal and vegetable produce, as exemplified at the various local shows throughout the kingdom, and especially those of the Royal Agricultural Society and of the Smithfield Club, the anniversary of which has just been held, and has given rise to this letter.

Considering the heavy losses sustained by the graziers and breeders of cattle, and the continued dread of a recurrence of the disease under which they lie, of a renewal of the decimation, the present show is perhaps better than could have been expected. The Devons, which, as usual, occupy the first five classes—the aristocracy of the show—are, I thought, fully equal in merit to those of any former occasion. The number exhibited is large—41; and in many instances in this, as well as other breeds, the judges must have been frequently perplexed by the near equality of merit. The first prize animal in Class 2, the property of Mr. C. Humber, M.P., is a splendid animal. There is one in the first class belonging to Mr. John Overman, of Burnham, Norfolk, which struck me as more worthy of a prize than some of its competitors. I have, however, been too long out of practice to pass criticisms upon the professional critics, who, there is no doubt, have exercised sound judgment.

The Herefords occupy the next five classes, consisting of 24 animals. These were not so good as usual, probably owing to the decimation the country suffered in its herds by diseases, only four of the specimens belonging to residents there. I noticed a beast belonging to Mr. Robt. Wortley, of Suffolk, as being specially meritorious, although it took only an inferior prize.

Dec. 15,

THE OLD NORFOLK FARMER.

BY A PRACTICAL FARMER.

The chief particulars of the exhibition of the above-named Club in cattle, sheep, pigs, implements of husbandry, and agricultural machinery have been so well and ably reported in the *Mark-Lane Express*, that it would be quite superfluous for me to make any observations in the nature of a report; there are, however, some things arising out of this, our country's annual gathering, which may be very properly and usefully brought before the public, and which it would be well to discuss and have thoroughly considered, so as to make these most interesting meetings of the greatest possible benefit.

The Club has adopted and carefully put in practice one very important feature in the show, whereby much true practical knowledge might be gained and diffused—I mean in obtaining the weights of each animal. Upon entering the hall of exhibition, I found it a very useful and pleasing addition to the interest with which I viewed the show. No one is well qualified to judge with accuracy the weight of animals of the many different breeds exhibited. He may approach with tolerable exactness in estimating the weights of cattle and pigs, but I cannot conceive of any accurate judgment in the various classes of sheep; hence the great value in taking the live weights upon entry. Many specimens in these classes are so beautifully shown, in exact proportion and shape, as to be very deceptive to the uninitiated. I took some trouble in comparing some of the sheep classes. The two prize pens of Leicesters, 23 months, shown by Lord Berners, very compact, beautifully-fed animals, weighed respectively, or averaged 6 cwt. 2 qrs. 21lbs. and 5 cwt. 3 qrs. 7lbs. live weight. The gigantic Cotswolds, 23 months, near them, averaged respectively 7 cwt. 2 qrs. 5lbs., and 7 cwt. 16lbs. Mr. Byron's 23 months' prize pen of Lincolns averaged respectively 7 cwt. 3 qrs. 26lbs.; Mr. Casswell's 23 months' 7 cwt. 3 qrs. 11lb.; and Mr. Morley's 23 months' 7 cwt. 3 qrs. 16lbs.; Lord Walsingham's 23 months' Southdowns averaged respectively 6 cwt. 2 qrs. 21lbs.; his 35 months', 6 cwt. 1 qr. 25lbs.; Sir W. Throckmorton's 35 months' pen, average 6 cwt. 3 qrs. 16lbs., his 23 months', 6 cwt. 1 qr. 7lbs.; Earl Radnor's 35 months', 7 cwt. 17lbs. Messrs. Russell's prize pen of Herefordshire Downes average 7 cwt. 1 qr. 26lbs.; Mr. Walter's second prize pen, 7 cwt. 8lbs. Lord Chesham's prize Shropshires weigh respectively 6 cwt. 25lbs.; Lord Wenlock's average 6 cwt. 1 qr. 21lb.; his 35 months' 7 cwt. 1 qr. 26lbs.; Mrs. Beach's 35

months' average 6 cwt. 3 qrs. 18lbs. Mr. Rogers' 23 months' first prize pen of Oxfordshire Downes weigh respectively 7 cwt. 4lbs.; Mr. Street's second prize pen, 6 cwt. 3 qrs. 11lbs.; Mr. John Overman's prize pen of 21 months' Long-wooled Southdown half-breeds weigh respectively 7 cwt. 1 qr. 31lb. Now, I think instruction of no mean order may be derived from some comparisons of the above breeds and weights. Lord Berners' 25 months' Leicesters weigh 6 cwt. 2 qrs. 21lbs. These are taken to be pure Leicesters, and finer specimens of the breed are seldom seen. Lord Walsingham's 23 months' Southdowns are equally fine specimens, and weigh precisely the same weight—i.e., 6 cwt. 2 qrs. 21lbs. I venture to say that few visitors at the show, nor even judges, would estimate the two pens at equal weights, their appearance and size being so dissimilar and disproportionate. The Cotswolds near them, to all appearance, from their size and proportions, seemed vastly to outweigh them; but not so, when the proportion of offal is taken into account, which is far heavier in the Cotswold than the Southdown. The Lincolns again average more than the Cotswolds—yes, considerably, which is unusual, and denotes advancement in the breed. The Hampshire Downes come nearest in weight to the Lincolns as a distinct breed; the Oxfordshires next, followed pretty close by the Shropshires. The Half-bred Lincoln and Southdown stand in point of weight next to the Lincolns, and are of superb quality. We will also take the sheep at 35 months; Lord Walsingham's 35 months' sheep weigh respectively 6 cwt. 1 qr. 23lbs., his 23 months' sheep, 6 cwt. 2 qrs. 21lbs., showing an actual loss by 12 months' keeping. Sir W. Throckmorton's 35 months' sheep, average 6 cwt. 3 qrs. 16lbs., his 23 months' sheep, 6 cwt. 1 qr. 7lbs.: this again proves a very trifling gain in 12 months (and goes far to prove that Southdowns are earlier brought to maturity than some other breeds). Lord Wenlock's Shropshires show an increase of more than 1 cwt., and Mrs. Beach's pen denote a tolerable increase in weight during the year, but not enough to justify over-holding; and in looking over my figures it will be found they tell conclusively against this over-holding, and that early maturity in the majority of breeds is to be sought for universally, and early feeding practised. We also learn the near approximation in weight of different breeds of sheep, as also their respective weights when got up for competition. The Lincolns, Cotswolds, Oxford, Hampshire, and Long-wool and Southdown half-breeds, are nearer upon a par as to weight than is generally supposed. The Leicesters, Southdowns, and Shropshires are of less average weight, but approximate near to each other. It may be said that this, in this single show, is no great criterion upon which to found a judgment. It may be so; still, I think all breeds were represented with tolerable fairness. At all events, by continuing this practice of taking the weight, good practical results will be ascertained ultimately. The like results may be obtained of the cattle and pigs. It will be important to collect these facts relative to cattle, because year by year we have a greater influx of cross-bred animals, many of them showing superior points, and greater weights than pure breeds. There were splendid specimens of cross-breeds at the past show, some approaching 1½ tons live weight. There was another feature in the show that struck me forcibly: it was the number of exhibitors from the upper classes, from Royalty downwards—the Queen, the Prince of Wales, Dukes, Marquises, Earls, Lords, Baronets, Knights, and Esquires. I should be the last to call such most important and praiseworthy endeavours in question; nothing can add more to a country's benefit than such noble examples; but what I do call in question is the possibility of ordinary breeders and country farmers coming into successful competition with such noble exhibitors, who are regardless of cost. I have seen many of their establishments for fattening stock, their conveniences, and the attendance most admirable, such as tenant-farmers can but very rarely imitate. The Smithfield Club have ample funds; what should prevent the Club from offering a series of prizes for tenant-farmer's classes only. It would greatly enhance their show in point of numbers. Tenants are not often found to compete against their landlord, simply because they cannot go to the expense. There are tenant-farmers who do successfully compete, but they are exceptions. I want to prevail upon the general class of farmers to aim at such distinctions, depend upon it they would be gainers in their business ultimately. The fattening of stock is, upon many farms, I had almost said the majority of farms, a matter of course. There is little or

no regard paid to warmth, ventilation, cleanliness, punctuality, in administering food, or the best application of the food given. Prize stock know of no privation or discomfort. Something approaching such care should be general with graziers or feeders of stock. The Club show is wholly confined to fatted stock. I should like a tenant-farmers' class in

each of the Devon, Hereford, Shorthorn, and cross-bred classes as a beginning, ultimately to be extended to sheep. [Of course it would be absurd to establish "tenant-farmer" or any other limited classes at a national meeting, the very heart of which depends upon the competition being open to all.—EDITOR F.M.]

INOCULATION FOR PLEURO-PNEUMONIA.

d

The following is the report in full of the deputation from the Cheshire Chamber of Agriculture that visited London:—

"We are sorry to have to say that the results of our inquiry respecting the efficacy of inoculation as a preventive of pleuro-pneumonia in cattle is not as satisfactory as we could wish. All the cow-keepers we saw in London spoke favourably of it; but the opinion in its favour we found was evidently given more as an expression of hope and of feeling than of direct testimony from actual experience. They resorted to it on a first attack of the disease, said they, but as a rule did not inoculate so long as their stocks were healthy. When asked why they did not inoculate all their cows as soon as they came into their possession, or when they were quite free from the disease, as a safer precaution if their theory was correct, they answered, 'There was always a risk of some cattle dying from the effects of inoculation, and they thought it best to let well alone.' The utmost support of the practice we got was that they thought their losses were less in an attack of pleuro when their cattle had been inoculated, than when they had to combat the disease without this protection. Since the plague had swept away their cattle, their sheds had been comparatively free from pleuro; but now it was making its appearance again, and they were again resorting to inoculation. That they did inoculate largely before the time of the plague was confirmed to us by Mr. Priestman, a veterinary surgeon having an extensive practice among cattle, who was recommended to us by Professor Simonds, as the best authority on the question in London, and who supplied us with a list of fifty-seven names of persons for whom he inoculated 4,515 cows from the year 1858 to 1863, and many cattle-keepers, he informed us, practised the operation themselves in their own stocks. On the other hand, he admitted that some cows took the disease after having been successfully inoculated, and that some died from its effects. The proportion of deaths was difficult to state, he said, as the rule with them was to sell their cattle to the butcher as soon as attacked. Their practice was to keep their cows in good condition, and as they were always meat it paid them better than to attempt their recovery.

"We visited nine large dairies in different parts of the town and suburbs, being introduced and accompanied by Mr. Priestman, and saw the effects of inoculation in several of them in different stages. The operation in itself is very simple. The hair being cut close off on one side of the end of the tail for about an inch square, an incision is made lengthwise well through the skin with a sharp-pointed knife and held open while one or two drops of matter are dropped in out of a bottle. The selection of the virus or matter is most important. Mr. Priestman prefers obtaining it from the lung of a cow that has had that disease three or four days only, and using it as soon as possible, as stale matter induces swelling of the tail and often necessitates its being cut off. A blow on the tail after the operation, and before the wound is properly healed, should be avoided, as it will cause much swelling and may soon result in mortification. Careful attention should be given daily, and prompt means used to reduce inflammation as soon as it appears. Of the 4,514 which Mr. Priestman inoculated 32 died from its effects, or three-quarters per cent., and 248 were seriously affected but ultimately recovered.

"We also had the advantage of a conversation with Professor Brown, of the Veterinary Department of the Privy Council, on the subject, in the course of which he stated that he had little faith in its effects. The evidence of its success was most conflicting. Professor Gamgee, he knew, was enthusiastic in its praise, but he had known cattle to die of pleuro that he had inoculated, some of which had suffered the loss of their tails from the operation. Professor Simonds, he

said, had inoculated cattle in the tail with gum-water and Croton oil, and had obtained the same outward results as with the matter from a diseased cow's lung. It was true, very likely, that few cases of pleuro, or perhaps none, occurred in some dairies in London after inoculation; but it was also true that there were many dairies which had not been visited by it for years in which inoculation had never been practised. Referring to the experiment being made at the instance of Mr. Tollemache, in Cheshire, in placing inoculated heifers by the side of beasts suffering from pleuro, and exposing them to the effects of contagion, he remarked that the trial would not prove much. To be perfect, heifers that had not been inoculated should also be placed with them. Some cattle seemed to be invulnerable to its attacks. Some facts which we gathered incidentally may not be without interest in our report to the Chamber. Dutch cattle, we were told, suffered less from attacks of pleuro and disease generally than any of the English breeds in London. An instance of the recovery of 25 cows out of 80 from plague was given us, 21 of which were Dutch and only 4 English. Foot-and-mouth disease seemed to prevail more or less in most of the dairies we saw, and it was thought that pleuro often followed in its wake. This, however, did not appear to deter dairymen from making fresh purchases. One man had just given £90 for three cows, which he would have to place in the same shed with about 20 others, nearly all of which had got foot-and-mouth disease. Milk-selling in London we thought must be profitable. Two only of the sheds we visited were in good keeping. One, containing about 120 cows, was a dark, ill-arranged building, and so crowded that we wondered not at the proprietor's statement that he had lost 16 cows per month for months together, from pleuro! Mr. Priestman strongly recommended the use of carbolic acid in cases of pleuro and foot-and-mouth disease, and he furnished us with a detailed report of the treatment he had pursued in eighteen different stocks of cattle, and the results. He proposes to apply it as a disinfectant, diluted with water, on the floor, walls, and ceiling, or roof of the shippens, applied with a syringe, and to administer it internally three times a day in suitable proportions, and asserts that when used early and plentifully, it is 'pleuro's master,' and soon drives away the foot and mouth complaint. Professor Brown also spoke favourably of the treatment." In a discussion which followed,

Mr. Aston was in favour of inoculating cattle for pleuro-pneumonia. He would not attempt to argue that it secured entire freedom from the disease. Those who were acquainted with the experiments made in the country and on the continent, must admit that there was a certain per-centage of cattle which had been inoculated that were liable to take the contagion; still, if they had been operated upon in a proper manner, he believed that the attacks were not so numerous or virulent, and the recoveries were greater from those inoculated than others. The suggestion which had been offered to them by Professor Brown, that two young heifers not inoculated should have been sent with those so kindly placed at their disposal by Mr. Tollemache, was very timely and worthy of their special attention. It appeared from an experiment made on the continent some few years ago on rather a large scale, that 34 per cent. of the cattle removed from healthy districts to those which were affected entirely escaped contagion, 66 per cent. were affected with the disease in a greater or less degree, and 17 per cent. of those died. It was proved by the experiment that the pleuro was a very contagious disease, and he also concluded from the trial that it was possible to remove stock out of healthy districts, to those animals that were suffering from pleuro, and yet

escape the contagion. His belief was that it would be better to associate inoculated heifers with the inoculated cattle, but he thought it would be unreasonable to expect that gentleman to expose any more of his stock to such a highly-contagious and destructive disease; and he considered it was a matter which the Chamber might very properly take up, and purchase two yearling calves or stirk heifers and send them to the premises where the infection existed. The cost of doing so would be very trifling, and he had no doubt the agriculturists of the county would look forward with very considerable interest to the final issue of such an experiment. He (Mr. Aston) had a conversation with a farmer on Tuesday evening, residing within about two miles of Tarporley, who lately had pleuro. On inquiry he ascertained he had only six cases, three of which had proved fatal, while there were three recovered. After the first four cases, he inoculated all his cattle; one was suffering from the disease at the time, and this recovered. He had also another attacked after the operation, but this also had recovered, and since that time, which was about ten weeks ago, his stock had continued in a healthy condition. He appeared to have strong faith in the operation, considering it was inoculation which had arrested the progress of pleuro.

Major LEIGH said he should like to know if any stock which had not had pleuro had been inoculated. As far as he could ascertain, inoculation had been tried only upon cattle that were suffering from pleuro.

Mr. ASTON said he had had a conversation with a farmer last Saturday, who had inoculated a herd of heifers. How many there were in it he (Mr. Aston) was not prepared to say; but the reason he did so was that he had the disease on his premises, and had occasion to bring these cattle, which were then two or three miles away, on to the premises. He inoculated them as a preventive, and they did not take the disease after their removal. They were inoculated while they were in a healthy state.

Major LEIGH wished to know whether they could tell him why the tail was the part chosen for inoculation?

Mr. TELLWRIGHT thought it was because they would lick the matter off if it was done elsewhere.

Mr. JACKSON said he was very happy to confirm the very correct report read by the secretary. In addition to it he would read the following letter, which he had received in reply to one he had addressed to a large cowkeeper, living at Kennington Park Road, London:—"Kennington Park Road, London, Dec. 15th, 1869: My dear Sir,—We have practised inoculation for the last twelve years with very good results, and in every instance that the cattle have lost a portion of their tails they have kept free from pleuro-pneumonia. We have lost several by the inoculation running up into the body, but that we could generally attribute to want of care. There are a great many that will not take when inoculated, and of course it is not a preventive; neither do we think it is much good unless they are inoculated when first they are brought into the sheds. Our own men that attend to them perform the operation, and great care is required in choosing the lung at the slaughter house.—I remain, yours truly, JAS. HIGGS.—G. Jackson, Esq." Some time ago he was reading a paper, by Howard, M.P., Mr. reported in the *Journal of the Farmers' Club*, part of which was to the following effect:—"Pleuro-pneumonia has made such ravages that M. Dumont and many others have adopted the practice of inoculation: the pus is obtained from the State Veterinary College, and inserted at the tail. If the operation is performed in hot weather the tail drops off through mortification setting in, but when done in cool weather no injurious consequences ensue. Having suffered much from this fatal disease among my cattle, I was determined to try it, but have hitherto been prevented by order of the veterinary inspector of the county, who has acted on the advice of Professor Simonds. The Professor opposes the practice; but those practical Belgian farmers who have had extensive experience, regard it, to use M. Dumont's own words, as a 'sovereign remedy.'" Since this he had addressed a note to Mr. Howard, and had received this reply:—"Dear Sir,—It would afford me much pleasure if I could give you any further information on the question of inoculation than is contained in my lecture on Continental Farming. All I can say is, that many sound, practical farmers in Belgium, Germany, and France seemed to place much faith in the practice. M. Dumont, of Fleurus, Belgium, is quite an authority in that country. On his farm I

saw a considerable number under inoculation. I have suffered much upon my own farm from pleuro-pneumonia, and hence I strongly urged on Mr. Forster before the introduction of his Bill the necessity for dealing with this and the foot-and-mouth complaint, as well as making provision for rinderpest. I agree with you that the only plan to rid the country of this ruinous disease, pleuro, is combined exertion to stamp it out. I believe the virus remains active for an almost incredible period. For three years in succession it broke out on my farm in one field, and months elapsed in the last case before fresh stock were put into it.—I am, yours, &c., JAMES HOWARD. P.S.—The Government departments of France and Belgium would doubtless supply information on the subject. I had a talk this week with Mr. Forster about inoculation, who thought it was not a matter for Government to undertake, but rather for the agricultural societies. I think the Royal might fairly be called upon—it has plenty of funds." He (Mr. Jackson) had a strong impression at first that inoculation was like a good many other things that had been tried to prevent the spread of pleuro, and was unwilling to believe that there was much to be relied upon in it; but from the inquiries he had made, and from a statement made by a neighbour of his who had been to Australia and had considerable experience in connection with the matter there, he was strongly inclined to come to a different conclusion. About five years ago a cow was brought out to that gentleman from England, which in about three months after landing was seized with pleuro. She was slaughtered, and all the animals in connexion with her were slaughtered too, and it was hoped that these strong measures would stop the spread of the disease. Unknown to them, however, some bullocks had been in connexion with the cow, and these being travelling bullocks, went up the country about 200 miles, and spread the disease along the whole track. Slaughtering was largely resorted to, but that was impossible in all cases. What they did not slaughter, however, they inoculated, and they found the practice exceedingly beneficial. They seemed to consider that they stopped it quite as much by inoculation as they did by slaughter, and he said that he inoculated thousands himself. If they inoculated with virus of a particularly malignant kind they lost them; but generally speaking the losses were not serious, and they had so modified their virus that they could calculate upon a very small per-centage of death. He did not recommend the inoculation of healthy stocks unless there was a likelihood of their coming in contact with the disease; but when there was actual disease he recommended all the cattle in contiguity with it to be inoculated. It was quite true that it could not be looked upon as an absolute preventive. Unfortunately in his own locality they had the pleuro about six months ago, introduced by a cow brought from Wrexham fair. After slaughtering nine or ten they sent for Mr. Dunn, of Tarporley, and inoculated the rest. Afterwards three cases occurred. One was violent, and they slaughtered it; the other two were milder, and they allowed them to live. Since then they have had no cases of pleuro whatever. This would seem to throw some doubt upon the value of inoculation, but the general impression in the neighbourhood was that the virus had not taken proper effect, as only three or four of the dozen cows which were operated upon seemed to have suffered inflammation in the tail. He would only say further that had he a case of pleuro in his own stock, he would consider it is duty to inoculate the whole stock at once.

Major LEIGH said he believed the matter was taken from the lung of a dead cow. (Mr. Jackson: A slaughtered cow.) It seemed to him that they would be more likely to have favourable results if they were to take the matter from a living animal, because the dead beast must have had the disease badly.

Mr. RIGBY said he believed the matter was considered best when it was taken from a beast that had had the disease three or four days. They did not like to take matter from cows in the last stage of the disease, as the blood might be poisoned, and this would produce mortification. Mr. Rigby then read a letter of apology for absence which he had received from Mr. Tollemache, M.P., in which that gentleman referred to the subject of the meeting, remarking that though inoculation was not found to be an infallible preventive it might be of great value to the farmer, just as in the case of vaccination, the beneficial results of which, though it sometimes failed, were universally acknowledged.

Mr. JACKSON said, with reference to the appearance of the inoculated beast when the operation was effectually performed, the tail was generally inflamed, and in some cases inflammation came on to a very serious extent indeed. A number of those seen by the deputation had had portions of their tails cut off in consequence, and one cow had had three pieces cut off her tail, which was then not more than five or six inches long. In some cases it produced a serious fever of the system, and in others they died.

Major LEIGH: Does it always create pus?

Mr. JACKSON: A little matter where it takes.

Major LEIGH: Do you know whether they have ever tried to make use of it? It seems to me that if that were the case, you would have a much better chance of saving your cow.

Mr. JAMES EDWARDS said that was a subject more for the veterinary world. The question before the meeting was whether the Chamber would recommend to the farmers generally the practice of inoculation? For his own part he thought if it was of any value at all it should be performed on the healthy beast, and that it would be unwise to leave the stable-door unlocked until the horse was stolen.

Mr. RIGBY fancied that when the inoculation took in a favourable way there was very little pus created, and that was the reason why a slaughtered cow was chosen in preference to a live one. However, he would make the inquiry from Mr. Priestman.

Mr. G. SLATER said he had been sceptical in regard to inoculation, but he was pretty nearly converted. He had some conversation lately with a man of great practical experience, who had lost three or four of his cattle by pleuro, and had then inoculated the whole of his stock, numbering thirty or forty, and had saved every one of them. He (Mr. Slater) asked him particularly what he would recommend in reference to healthy stock, and he said this—he certainly would not inoculate healthy stock unless the disease made its appearance, as there was a little risk and expense with it; but when he had an animal suffering three or four days, he would slaughter it, take the virus from its lung, and inoculate the rest, and he should confidently calculate upon saving them. He (Mr. Slater) had seen another farmer who gave evidence of a similar character, and he thought they were not only bound to listen to evidence, but that when it was so strong it became absolutely irresistible. Mr. Slater then referred to the case of a friend who had been for some years residing in South Africa, where he said inoculation was very generally practised, and he laughed at the ignorance of the Cheshire farmers, who were only just making experiments to test its value. The things about which they should take particular care in manipulation (said Mr. Slater) were that the virus was properly obtained, that cattle were not inoculated till disease appeared upon the premises, and that the very best skill was procured to conduct the operation. The animals, too, should be carefully watched to see that they did not lose their tails, which frequently resulted from pure neglect. He thought if they attended to these things they would find good reason to put faith in inoculation.

Lord EGERTON, the chairman, said, after the very able report which had been read, the question to consider would be this—whether the Chamber considered itself in a position to commend to the farmers of Cheshire the process of inoculation? He confessed that after the strong opinion which had been pronounced by the gentlemen in London upon the subject, he hardly thought they were in a position to make a positive recommendation to that effect. Mr. Tollemache having been good enough to place two inoculated heifers at their disposal,

he (Lord Egerton) would like to suggest that, in case of any of their members having the disease upon his premises, their Secretary, as an experiment for the information of the Chamber, should be empowered to pay for the inoculation of the remainder of his stock. They would then be in a position before the summer to see whether inoculation had answered. One single case he thought was not sufficient to base the recommendation of the Chamber upon. He should like to make a remark with respect to carbolic acid. He (Lord Egerton) had had the foot-and-mouth disease through the whole of his stock, and they found the use of carbolic acid diluted both in washing the mouth and feet, and in some cases taken internally to be of the greatest value. At the time of the riderpest he lost a great number of cattle out of doors. They took the remainder into the shippin, where they remained nearly a year and a-half shut up, chlorine gas being freely used, and they found it the best disinfectant that could be employed. It never affected either the cattle or the men, and it was no inconvenience whatever. He was happy to say that in consequence of the able measures taken by the Chief Inspector, Captain Smith, with the co-operation of the farmers, pleuro had not spread very extensively in this county. The number attacked from the 28th of August to the 11th of December was 123, out of which 26 had been killed for burial, 31 for meat, 23 had died, 38 had recovered, and five were under treatment. In the case of foot-and-mouth disease during the same period 2,249 had been attacked, four killed for burial, three for meat, 11 had died, 1,935 had recovered, and 316 were under treatment. He might say likewise that the other day one of the committee on the subject had looked over the accounts of Capt. Smith, and had found that it had been done at a very small expense indeed, not exceeding £80 for the three months, and out of that a-half or two-thirds had been paid for the dresses of inspectors and other things which would not recur. The county then might feel that they had a very efficient body of inspectors at a very small expense. With regard to stock, he should strongly recommend that, if they tried the experiment, they should do it with cattle of a certain age. Very young stock were not at all liable to the disease. It went through the whole of his (the chairman's) herd of oxen, but out of 700 head in the adjoining park out at ley not one was attacked. Cows in milk, and especially those in full milk, were much more liable to the disease, and when they had it, they had it far more severely.

Mr. MILLINGTON, who had the charge of Mr. Tollemache's heifers, said that up to the present time they were very healthy. He himself had had 12 cases of pleuro altogether out of 20 cows. Early in October he had his stock inoculated, but eight cases had broken out since. There was no inflammation of the tail, however. Four had died, one was killed, six had recovered, and one was ill now.

Mr. JACKSON said he was quite of Lord Egerton's opinion that they were not in a position to recommend the absolute adoption of inoculation, but they ought not to lose the opportunity of trying a further experiment. He would move a resolution to that effect.

A resolution was then submitted to the meeting to the effect that, "Not being in a position at present to offer a decided opinion on the value of inoculation, the Secretary be empowered to purchase cattle for the purposes of experiment, and that one or two of the milking stock be left not inoculated, in order to institute a comparison."

The resolution was carried.

SMALL FARMS.

At a dinner at Cirencester the other day, Mr. EDMUND RICE said: A word or two has been said about the agricultural labourer. This morning I looked over some of my books, and I find I have some men living rent free and taking wages from me of from £70 to £80 per annum. We had just now a remark that the Irish were going to have a plot of land and a cottage to live in. Compare this with what the labourer takes from me. He takes from me five acres of the best wheat I

have grown in the year; he takes from me the same in value which is grown in the county of Gloucester on eight acres a-year—what used to be grown on 16 acres. It is perfectly ridiculous to talk of these little occupiers. They may perhaps grow enough to keep their families, but what are we to do with those who don't live in a cottage at all? I can say I do wish the landlords would sweep away many of their restrictions from the statute books, I feel convinced that if the

tenant had what liberty it is desirable he should have, he would not only improve his own estate, but he would improve the land and the labourer, and the country generally. As I am on this point, I beg to say that I perfectly believe that you can sow cereals on strong land without any farm manure.

Mr. BAZLEY said: Our population increases rapidly, but the opportunities for employment do not appear to increase in the same proportion. In passing through the country one can hardly feel being struck with the magnitude of the estates and the size of the farms. Now, I am not going to say anything in contravention of large farms. Where capital is available there is no doubt that large farms can be managed more profitably than small ones, and I know more than one estate where the largest farm is in all respects emphatically the best; but like the manufactory, like the railway, they must be conducted on sound commercial principles; and I venture to suggest whether it would not sometimes pay better for the farmer to be content with a less amount of acreage, to pay a less rent for that quantity, to cultivate it more fully, and to employ more labour and to pay less poor-rates. But there

are two kinds of capital required for this efficient cultivation. There is the tenant's capital, but there is also the landlord's capital, which is necessary for the erection of suitable buildings, and very often this latter capital is not forthcoming. I will venture to place my Lord Bathurst in the witness box on this occasion. You have heard his lordship deplore that many landlords who are called upon to make improvements are really unable. But why should this be so? The wealth of the country increases in a rapid ratio. The English people are ready to invest their savings in all sorts of schemes, at home and abroad, limited and unlimited; but as a rule the spare capital of the country does not find its way to the land. For the existing laws with respect to the transfer of land are such that in their effects, in many instances, the legal difficulties are insurmountable in the way of investing money upon it; but I do not hesitate to avow my conviction that the laws of strict settlement and entail are those which keep land in an uncultivated state (great applause), which lend a shadow of ownership when the substance has gone, which keep the land inactive, and prevent an increase in the employment of the people.

SUSSEX OR SUSSEX-DEVONS?

At the dinner of the Hurstpierpoint fat stock Show on the Thursday in the Smithfield Club week, Mr. GEORGE DARBY, of Marklye, said: I was very happy when I came here to-day to see so excellent an exhibition of stock, and I am glad to say we were equally fortunate this year at Hailsham, where we had one of the most magnificent shows we have ever seen. I have for nearly 50 years taken a great interest in Sussex stock, and I am not sorry to have this opportunity of saying a few words on the breeding of Sussex stock, to which our attention has been lately directed in rather a singular way. I have been very much amused by an assertion in one of the London papers that the great improvement in Sussex stock is owing to their having been crossed with Devons. As I have said before, I have been greatly interested in the breeding of Sussex stock. I have bred many myself, and I have been among the large herds of the county, and I can unhesitatingly say there is not one word of truth in it. I do not say for one moment that no one has not for the sake of an experiment crossed Sussex with Devon; but that the improvement in the Sussex stock of late years is in consequence of crossing with the Devon, or any other breed, I entirely deny. I will tell you what has improved the Sussex stock. I remember many years ago, when Mr. King and other breeders got together to puff off some of the large-hipped gentlemen of those days with narrow chests and light fore-quarters. I told them they never looked a bullock in the face, that they would not produce good animals unless they did so, and if they wanted to keep up the character of the Sussex stock, they must cross with animals which did not show such deficiency from other parts of the county. They took the question into consideration, and the consequence was, they went and got animals of good strong constitution from other parts of the county—from Rotherfield, Mayfield, Barton, and other places, from Mr. Selmes, Mr. Noskes, and Mr. Tilder Smith. They crossed their own stock with those animals, both being pure Sussex, and thereby improved the breed in those points in which it had formerly been deficient; and whoever said that crossing with Devon has produced that result, has simply stated that which is not true. At the same time there has been, I am glad to know, a great improvement in our stock, but it is mainly in consequence of the competition at these shows, which enables men to find out the faults in their own animals. We also sometimes see the result of crossing with other herds, and, as I told Mr. Marshall, I saw a cross here to-day that wanted crossing out. I am delighted to hear that there is such an excellent show of Sussex stock at Smithfield. I have not been able to get there yet, but, if possible, shall go to-morrow. For many years, as you may remember, justice was not done to our native breed at Smithfield. I had been a very old subscriber, and I said I would cease to give a subscription until our fair demands were granted. Shortly afterwards the Sussex classes were established. I want to know whether anyone here who has seen the small squabby Devons would like to see our breed crossed

with them. And I should be very glad if an opportunity were afforded for an investigation in which the breeder of stock from different parts of the county might take part—to show whether or not the improvement of Sussex stock has taken place in consequence of crossing with Devons.

Mr. JAMES DUMBRELL, of Ditchling, said: Last night I was dining in town with a few friends, and among them one of the judges of the Smithfield Club. We all agreed that the show of Sussex stock was remarkably good. My friend, the judge, said to me, "You quite understand the improvement is the effect of having the Devon breed brought into the county." I am not a breeder of Sussex stock myself, and do not pretend to know anything about it, but I took on myself to give that assertion an unqualified denial; and I threw the burden of proof on him, he having made the assertion—the proof that Sussex men have had Devons brought into their herds, and have crossed with them. I have asked Mr. Darby, Mr. Marshall, and every other breeder I have seen to-day, and they scout the idea, and say that, instead of importing Devons into Sussex for breeding purposes, the Devons would be improved by taking stock of us. [Notwithstanding this, the best fat cow at Hurstpierpoint, described as a Sussex, is entered as bred by Mr. James Dumbrell, of Ditchling.]

Mr. DARBY remarked that he did not say there were so good Devons; what he said was, that Sussex stock was not improved by being crossed with Devon. He had certainly seen some very good Devons, as evenly fattened as one need wish to see, in the market that day. It was a curious fact that some years ago a gentleman from West Sussex visited him at Marklye for the purpose of purchasing, and he did purchase a Sussex bull to send into Devonshire; but he (Mr. Darby) would not be justified in saying that all the Devon stock had been improved by that Sussex bull.

Mr. HAMMAR, the Vice-Chairman, said that he was not a breeder; but he fattened a great many animals in the course of the year. With regard to the two breeds, Sussex and Devons, if he wanted to buy lean stock at a fair, he should not buy Devons. He only wished there were more breeders of Sussex stock, that those who did not breed might have an opportunity of picking up Sussex steers.

At Horsham, Mr. CANE said he recollected fifty years ago, and that was a pretty good way back, and he knew pretty well every breeder in this county; but he didn't know anyone but Mr. Brandon who had crossed a pure Sussex with a Devon, and that was only one. With that exception, and he knew from one end of the county to the other, there had not been one crossed with the Devon stock.

Mr. LEE STREER said: It may be five-and-twenty years ago that I went to the eastern part of this county, and bought a cow of Mr. Fuller, of Mays, and from that cow all the animals I have exhibited have sprung. From these animals I have exhibited—two in London and two here to-day—all from the same stock. All these are from one particular lot of cows

down upon a farm of mine, and are all by the same bull. They are as perfect in their breed, and more especially in their constitution, than any other animals I have ever been possessed of. Why it is said that they have been crossed with a Devon, I know not; but if I may be excused for making a pun, it may be in consequence of a *cross* feeling of a reporter from some of those more enlightened papers. I think anybody who looks at our stock—and mind me, I do not cry a word against the Devons, I think it is a beautiful breed, because it is the most perfect of their kind that is exhibited, but let them keep them if they like—will see the difference. We all differ in our wants. We want power as well as symmetry and good constitution—animals that will do our work in more ways than one, and in a more effective manner than by showing them at our exhibitions. We want them to do anything that may occur; but I most emphatically deny that there has been any cross whatever. We never intend to have a cross.

The *Sussex Express* says: No doubt, of late years, there have been great and constantly increasing pains taken with our stock, and we have, as Mr. Darby said, gone further afield to supply the deficiencies in form. But there was no occasion for Sussex men to try a cross with the Devons to remedy defects in their stock. We need only look back to that olden time, when, as tradition has it, and no doubt the story is somewhere on record, Mr. Selmes offered to show one hundred Sussex beasts against one hundred of Earl Spencer's famous Shorthorns, to feel certain that at that time, perhaps the better part of a century ago, there was, at least, one great herd of the Sussex breed, which was of rare excellence in every possible respect; and that herd, though it might be neglected for

a time, must nevertheless have kept up in the far east of Sussex, a high standard of excellence amongst those of our breeders who were anxious to improve their stock. What has led to the present improvement, which is universally admitted by the press and the public to be unexampled in the history of breeding, is simply the giving Sussex stock a class at Smithfield, and the consequent compilation of the *Sussex Herd-Book*, for which we are indebted equally to West and East, to Messrs. Heasman, of Angmering, and Mr. E. Cane, of Berwick Court. In this way it is that pedigree has been more and more studied, and the value of particular strains of blood has been more accurately ascertained, and brought into play. It does so happen that in the very case in which it might be supposed that one gentleman was more likely than another to have risked the Devon crossing, there is a special ground for the belief that that has not been the case. Mr. Lee Steere, of Jayes Court, Dorking, does just live out of the county of Sussex; but one of his successful beasts was actually bred by Mr. Woodman, of Southease, who would never have dreamed of trying to improve his stock by a cross with Devons. Mr. Lee Steere, then, though living out of this county, has shown us what he can do, not only with animals of his own breeding, but with those actually bred in Sussex, and we cannot doubt that the same causes which made him successful with the one, led also to his victories with the other. What we believe is, that the Sussex breed is not only not crossed with the Devon, but as the improvement in it goes on, it will one day be found no mean competitor for that blue ribbon of the yard. [It will be remembered that only a year or so since a Sussex ox was within one, or at least two, of taking the Gold Medal of the Smithfield Club.—EDITOR, *M. J. E.*]

FAT v. DAIRY STOCK.

At the quarterly meeting of the Dalrymple Farmers' Society, at Dalrymple, there was a large attendance of members and others. Mr. Smith, Barnford, president of the society, occupied the chair. The subject for discussion was, "Whether does a Dairy or a Feeding Stock pay best?"

Mr. WILSON, Woodlands, read the following paper: This is a subject, in my opinion, of very great importance, and well worthy of being discussed by such a meeting as this. I am at a loss to understand how it was not taken up long ago, and that by abler hands. Whatever view we may take as to which of the classes is the most profitable, I am sure we shall all agree that it is second to none in all our agricultural departments. In the management of our respective holdings we must always keep prominently before the mind how we are to provide for our stock—the greatest quantity and finest quality of food; for according to the amount of stock we can keep on a given portion of land depends to a great extent our success or failure. It is a bad sign of an occupant to see a small stock on a common rotation farm. I would not give much for that party's success. But whatever be the number of our stock, the principal thing is to have them well-fed, well-housed, and properly attended to, with plenty of grass in summer, and an ordinary amount of house-feeding in winter, being always careful to guard against waste or extravagance, as there is a limitation in feeding that will pay to come up to, but won't pay to go beyond. We must always keep in view wherein the profit lies. But to come to the point at issue, whether a dairy or fattening stock is the most profitable; we are apt to look at certain things from certain stand-points, and according to the view we take we fix our opinions, and these opinions may not easily be changed unless something is brought forward to prove that we are wrong. We are sometimes ready to be biased by the thing we are most familiar with, but in every case we ought to discuss the thing within ourselves without partiality for either side, and not leave, as it were, a stone unturned. In times of strong competition for farms, with manure rising in price year after year, it becomes us to bestir ourselves if we are to exist at all as a class. We must be at the utmost stretch of our abilities, and have the kind of stock that is most profitable, although it be not the kind we have been used to. It won't do for us to move on in the old track, if there is a way that thousands have proved to be better

for us to take. I have tried both ways. I had my own suspicions at first, but I have found that a fattening stock is the most profitable. The expense of utensils and working a fattening stock is very small in comparison with that of a dairy, and the income per head will only in exceptional cases be in favour of the dairy. Whereas one third more in number can be kept of fattening than dairy cows on the same portion of land in summer. Therefore the balance comes to be greatly in favour of fattening stock. To make it as clear as possible we might take, for example, two parties entering into two farms at the same time. The farms are of ordinary size, alike in every point, and in the same locality. Both tenants start with their respective farms under very propitious circumstances. A prefers a dairy and B a fattening stock. A purchases for his grass land, at May, 1st 30 cows at £12—£360, and B 45 young cattle at £8, which makes £360. So far both are alike. Both have to see that their fences are secure before turning their cattle on their pastures. B has now only to see that his cattle are looked to once or twice a day during summer to see if they are all right; while A on the other hand has a great deal of expense and anxiety to encounter that B knows nothing of. In the first place he has to provide a considerable number and variety of utensils, for the proper management of such a dairy; and in the second place he must look out for a first-class dairy-maid, and I am sure all will be at one, that such an individual is not easy to be got. There must be two other women to assist, for where there are 30 cows you can't do with less than three women, whose board and wages will take about £60 a year—certainly they will do the ordinary house work, and if necessary one of them occasionally out-door work, which will reduce the above sum by about £20, leaving £40 for attendance on cows. Then to keep up this dairy at its original state must take about £20 a year for tear and wear of cows and utensils. I think the most systematical mode is to sell out a certain number of the oldest and least productive cows every year, and fill their places with queys in-calf. Still in this way there is a loss of produce, if we consider that a quey the first year does not give as much produce by one-third as an ordinary cow. We might adopt other methods, but the above, in my opinion, is the simplest in practice. To keep a cow one year will take about £11 6s., in the following pro-

portions, viz.: 24 for pasture, 21 for cut grass, vetches, and soft turnips, 23 for straw and hay, 85s. for turnips, and 30s. for beanmeal and bran. There is to be added 10s. for wear of cows, 4s. for tear and wear of utensils, and about 20s. for work, making a total of £13 5s. The dung might stand against the last two items and thereby reduce the expenditure by 30s. Still, after all, it is questionable if there are many dairy stocks in this district in ordinary seasons giving produce to that amount. Now, what is the use of a large income if our expenditure go beyond it? We are sure to get into difficulties, and may not get easily extricated. As to a fattening stock they are allowed to roam on their pastures at full liberty until the first or middle of October. They should then be brought into well ventilated byres and kept warm and quiet, the byres should not have more than eight or ten double stalls each, so that one lot may not be disturbed while the others are being fed, and care should be taken as to the kind, quantity, and quality of the food they receive so as not to allow them to fall off in condition, as cattle at first are apt to do when taken from pasture to stall-feeding. I think the most economical plan of feeding is to grow on the farm nearly all they require, and any one who has accommodation could not send their farm produce to a better market, according to present rates, than to consume it with feeding cattle. I would begin them with cabbage, which are in a good state for lifting at this time, and nothing suits the constitution of the cattle better at the first stage of stall-feeding. About half an acre will supply 45 cattle with two meals a day for two weeks at a cost of a little less than 1½d. each per meal. I would prefer boiled unmarketable potatoes for the third meal, mixed with a variety of stuffs, such as chaff, corn dust, and a mixture of beans, light wheat, rye, barley and oats, all ground up together, giving about 3lbs. of this bruised grain to each and every day. Under this treatment they are sure to improve from the first day they are housed. When cabbage and potatoes are done give them turnips instead twice a day, 28lbs. sliced raw, and once boiled, with the usual mixture of chaff and bruised grain. I approve, during the last six weeks or

two months, of giving them per day twice boiled and once raw food, and with double the quantity of bruised grain and a little oilcake, always giving straw or hay after each diet. To provide food as I have described, will take for pasture, from 1st May to 1st October, £23 10s., and for stall feeding from 1st October to 1st May, £10 10s., and 15s. for attendance and implements making a total of £13 15s. The manure will reduce the expenditure about 45s., which leaves £11 10s. to be added to 28 inland price, which makes £19 10s. for each animal. With ordinary markets they can be made worth fully that sum. The kind of stock I prefer for stall-feeding is either pure Ayrshire bullocks and heifers, or a cross between Ayrshire and Shorthorn. But I would not too partial to any particular breed. Get a well-moulded frame, be careful in making purchases, and there is less difficulty at the end. In ordinary cases we don't allow such a length of time for stall-feeding well-conditioned cattle, but by giving them seven months' stall feeding after five months' good pasture is the sure way to bring them to perfection. In a herd of any considerable size there is always a per centage that don't require much stall feeding. After good pasture, select these into a byre by themselves, and send them off as soon as ready, and fill their places with lean cattle; by adopting this plan a double profit may be gained at no extra cost of feeding stuffs. In deference to those who may hold different opinions on this subject to myself, I have endeavoured to give my views in as moderate a form as possible, and have only touched on some of the points, leaving plenty of scope for discussion, so that more light may be thrown on such a subject.

After the reading of the paper, a discussion followed in which the majority of those present took part. A few expressed themselves as in favour of the feeding system; some questioned if the land in the locality was suited for such a system, as far at least as regards its grazing qualities; while others thought that the better way was partially to adopt both methods. The greatest number, however, expressed themselves as inclined to keep to the dairying, so long at least as anything like present prices ruled.

THE TESTIMONIAL TO MR. JOHN CLAYDEN, OF LITTLEBURY.

At a dinner at Saffron Walden, there was presented to Mr. Clayden a testimonial in recognition of his services to agriculture. The testimonial took the shape of a centre-piece or candelabrum, a service of dessert dishes, six in number, a highly-chased waiter, and a watch, value £35.

Colonel BRIZE, M.P., the Chairman, in presenting the testimonial, said: The people at large appreciate fully Mr. Clayden's valuable services in connection with, and as a member of the Council of the Royal Agricultural Society, as a member of the Council of the Smithfield Club, as one of the committee, or as the honorary secretary, I should say, of the Agricultural Benevolent Association; as chairman of the Home Cattle Defence Association; and last, though not least among many others, as chairman of that great commercial and agricultural undertaking, the Islington Agricultural Hall. All who have been connected in any way in business matters with our friend wish now publicly to acknowledge his great services, and the great satisfaction he has given both to the shareholders and the public at large in these vast undertakings. I think I may say that had not Mr. Clayden brought to bear great diligence, great intelligence, great industry, and great business-like habits, those great undertakings would not have advanced to the extraordinary extent they have. And now what shall I say as to the local character of our proceedings? I will endeavour not to tax you, sir, by any personal allusion; but I will draw you, gentlemen, a picture of a man of genial disposition, of pleasing exterior, with a heart large enough to rejoice with those who do rejoice, and feeling enough to weep with those that weep—a heart warm enough to glory in the success and to sympathise with the misfortunes of his fellow-men—a man with a kind word ever ready in his lips for rich or poor alike—a man who cannot be spoiled by flattery—a man who cannot be put down by vulgar prejudice—a man always prepared to deny himself for others—a man of straightforward business-like habits, of uncompromising honour, and of unswerving integrity.

Mr. CLAYDEN said: What have I done to deserve this? I feel that it is due more to your generosity and kindness than to my own deserts; but I beg to say that no greater gratification could possibly be felt by any man than to know that he enjoys the respect and esteem of those among whom he moves, and in no way could that be more fully and forcibly exemplified than by your presence. Gentlemen, I trust I shall ever be sensible of your kindness. It is true that I have tried to advance agriculture in every way I possibly could; but when I look around this room, I see many friends who on all occasions when I have requested it have given me their counsel, and, when it has been needful, they have not refrained from opening their purses. Without their aid I should not have been able, on many occasions, to serve your cause in any effective degree. I trust I shall continue any efforts I have made, and that I shall still be able to apply to my friends in this neighbourhood, whose confidence I have the good fortune to possess, for their assistance when anything beneficial to agriculture can be done. It is true that from a boy I have been very fond of agricultural pursuits, because I have looked upon agriculture as one of our oldest institutions, and one of the best interests of the country. I have ever thought that the land in this country should be farmed in such a manner as to produce the utmost for the country in general, and the utmost benefit to the occupier and the owner. It falls to the lot of very few men to be presented with such a testimonial as you have thought proper to offer me this evening. It was more than I could in any way expect, and your great kindness has almost overpowered me.

Mr. C. S. READ, M.P., said: If I might enlarge on one portion of the services that Mr. Clayden has rendered to the agricultural interest, I would specify that of his great efforts and exertions to secure for us what we must eventually have—separate markets for the sale and slaughter of foreign stock. And, now, sir, I believe that the measure of inefficiency in the veterinary department of the Privy Council has almost reached

its climax. Let me just review for one minute all that they have done to the agricultural interest. Some years before there was any special department the government employed certain professors, who were supposed to watch over the health of our flocks and herds. It was these professors who first told us that foot and mouth disease was atmospheric—it was these professors who, when we had the misfortune to have the sheep-pox, told us the best way of getting rid of it was inoculation, whereas we know if you want to keep and extend it you must inoculate, and if you want to exterminate it there is nothing like slaughter and isolation. It was these professors who were sent out by government years ago to watch the cattle plague, and they came home and told us that foreign countries took such special precautions against the spread of this disease, that it would be impossible for it to come here. It was Professor Gamgee who told us differently, and that whenever we received direct importations from Russia the cattle plague would come. Well, it did come, and although the authorities of the government knew perfectly well what it was, they disregarded the universal request that was made from the whole country to close the London markets, and they allowed that pestilence to irradiate from the London markets to almost every county in England. I say, sir, further than this, that the government of the day, or rather the officials of the day—and they are officials still—set about work at that time to kill our stock without awarding us any compensation, and when the cattle plague commissioners made a report and said, "If you cannot give compensation you have no right to kill," they withdrew that order and allowed the cattle plague to run rampant over the land, and it was not until such time as parliament took up the matter in hand and used vigorous measures that it was stamped out. Now, sir, I say that these permanent officials at the Privy Council Office are somehow or other totally set against the agricultural interest, or why should they so persistently and energetically strive to prevent the establishment of these foreign markets? When the government changed, and Lord Robert Montagu was at the head of affairs—a talented and clever man who had not turned his attention particularly to cattle—they crammed him and primed him in such a manner, that he made a speech against separate markets, which has done more I believe to injure our cause than has been done to benefit it by all the good and excellent speeches that that nobleman has made since. And then, when Mr. Forster went there—a man who was well inclined to the agricultural interest—they would not allow him to accept one

single amendment, although they have since embodied some of these in their orders. But what have they done? They told us that when this wonderful bill was passed we should require no more Privy Council orders. No sooner, however, did the bill become law than they issued orders about as long as the bill itself, and about a month after that they put out another order, making all the restrictions of pleuro-pneumonia apply to foot and mouth disease. It is a very easy matter indeed to shut the stable door, but now that that mad-horse disease is galloping all over the country, it will take a precious long time before we can curb and confine him again, and I do say that the conduct of the government, when they knew that they had this foot and mouth disease raging on almost every part of the continent, in allowing foreign sheep that had been associated with diseased animals to go all over the kingdom, was something that calls for the strongest reprobation. Why, what have we, the farmers of England, done that we should have the floodgates of this disease opened upon us? We could have kept the disease out, and would have done if we had had our minds. I will take my own case. What have I done that I should have 70 or 80 cattle nearly fit for market now thrown back at least six weeks, to say nothing of the sheep I have had affected with this most tiresome disease—what have I done that I should be robbed of at least £200? I hope and trust that when the poor artisans and the unemployed labourers happen to get a bit of meat again, they will remember that it is the authorities at the Privy Council Office that have increased the price of meat at least 1d. per pound, and that they will not say it is the bloated farmer who gets all the profit, for I can assure you, speaking for myself—and I think I may speak for you too—that if we have fruitful seasons and healthy stock we would rather sell meat at 7d. a lb. than sell it at 9d. when the advance is caused by disease. I believe, sir, that if a body of roughs were to go down to the Privy Council Office, at Westminster, smash the windows there, break the furniture, and chase the officials so that they had to take refuge in the Abbey, it would have more effect than all the facts and arguments that we have for so many years put calmly and temporarily before them. And why do I say so? Because we are told that nothing can be done in this our time except it is urged with a little physical persuasion as well as moral force.

The company was chiefly made up from the district, and the other speeches addressed to local topics.

THE PRODUCTION OF CHEESE.

The production of cheese is becoming an important branch of our agricultural industry, and the demand both for home consumption and for export is every year increasing. Factory-made cheese will compare favourably with the best of English and Dutch manufacture. The business of making cheese in the United States has long been profitable to the farmer and dairyman; and that it will continue to be so for years to come seems highly probable, in view of the limited crop and the growing taste of our people for food of this description. It is estimated that there are in the United States and Canada 1,000 factories, whose average weekly production is equal to 117,250 boxes. The cheese made in the United States and Canada in 1887 reached 215,000,000, and in Great Britain 179,000,000 pounds. The consumption in America during the same period amounted to 160,000,000 pounds, and in Great Britain to 400,000,000 pounds, leaving a deficiency over the joint production of the two countries of 75,000,000 pounds. This deficiency was supplied by Holland and Belgium. The principal States engaged in the manufacture of cheese in this country are New York, Vermont, Massachusetts, Pennsylvania, Illinois, Ohio, Michigan, and Wisconsin. Western New York, the Western Reserve, and some sections of Illinois and Michigan, enjoy a deservedly high reputation for the excellent qualities of the products of their dairies. England has long been justly celebrated for the abundance and superior quality of its cheese. Cheshire, Stilton, Derbyshire, Suffolk, and Cheddar are the best known varieties. Gouda

cheese, the best made in Holland is very pungent, which preserves it from mites, and this pungency is attributed to the fact that muriatic acid is used in curdling the milk, instead of rennet. Parmesan cheese, made at Parma, in Italy, owes its rich flavour to the fine sweet herbage of the meadows along the Po, where the cows are pastured. The best Parmesan cheese is kept several years, and none is sold until it is at least six months old. Swiss cheese is made, in part, of skim milk, and is flavoured with fragrant herbs. They usually weigh from 40 to 60 lbs. each, and are exported in casks, each of which contain ten cheese. Westphalia cheese derives its flavour from the curd being allowed to become soured before it is compressed. Dutch and Swiss cheese contains, according to chemical investigation, from 26 to 40 per cent. of nitrogenized matter, considered the most nutritive constituents of food. The best cheese is from 25 to 100 per cent. more nutritious than bread and meat, which contains only about 22 per cent. of nitrogen. The superior qualities of cheese has been repeatedly proved by the experience of labourers in those countries where it forms one of the principal articles of food. To delicate stomachs cheese is objectionable, on account of its slow and difficult digestion; but to individuals of great physical strength, it is a healthful and agreeable article of consumption. In combustible or heating qualities, cheese is only exceeded by oil, butter, and like unctuous substances.—*New York Mercantile Journal*.

THE CHEESE FACTORY QUESTION.

At the annual meeting of the members of the Derbyshire Agricultural Society, beyond the formal business of the meeting, it had been announced that Mr. Crompton, who presided at the last annual dinner of the Society, would bring before the members the question of producing cheese on the factory system, which prevails largely in the United States, which has of late been the occasion of considerable discussion in South Derbyshire. The interest taken in this question led to a very large attendance. Dr. Hitchman presided.

Mr. CROMPTON said for an agricultural society there could scarcely be found a question of greater or more pressing importance at the present time than the system of factory-made cheese which was adopted in the United States. He thought every one of them who had bestowed the slightest study on the subject, must feel that the people of that country had in a very short period made gigantic strides in the mode of making cheese. It had raised the value of the product so much that it did become them, as English dairy farmers, to consider the means by which those great and important results had been achieved. He did not know that he could give them much information; but he had, in company with their secretary, Mr. Smith, endeavoured to get some information on a subject of such importance. As far as he was able, he would readily and gladly place it before them. In the first place, they would have to consider who were the great antagonists with whom they had to deal, and what class of men they were who now competed with them in the supply of cheese for this country. The American mind possessed all the endurance and all the persistency of that of the Englishman; peculiarly sharpened by the circumstances into which they had been placed. The fact of their having been placed in a new country, which they had had to subdue and civilize, and out of it to provide for their various wants, had made the Americans quick in acquiring knowledge, and successful leaders in most of the clever and important mechanical inventions of the present day. In a few words he would tell them all he had been able to learn of the factory system of making cheese, but he thought he might use another word and call it the co-operative system of cheese-making. When in Liverpool a short time ago, he was in company with one of the largest importers of American cheese, and he had heard him make a remark which struck him very much. "In early life," the gentleman said, "I was a large buyer of English cheese, and I was really driven to give up that particular branch of trade by the great want of uniformity in the class of cheese I had to buy. It became excessively laborious; there was an absence of uniformity in colour and quality and other material points, which rendered it a very difficult matter to buy cheese in large quantities. But when, on the other hand, I turned my attention to the Americans, and became a large importer of American produce, I found this advantage—that they possessed a very great share of persistent uniformity in the cheese they produced." If this system of co-operative cheese-making should bring amongst them an improvement as to make, and a uniformity as to colour and quantity of cheese, it would be the means of greatly benefiting the dairy farmers of this county. It became them who had an interest in this subject to deal with it. In the districts of America, where the cheese factories were situated, there was no material difference, so far as he understood, in the land or the circumstances attached to dairy farmers as compared with this country; but there was this difference, that instead of being tenants, as a rule they were possessors of the farm, and instead of following the lame and halting system here persevered in, of each dairyman having his own particular dairy, and his own plant for making cheese, and keeping very far behind as far as perfection in the mechanical arrangements necessary for the purpose, the Americans had marked out their districts, erected their own wooden buildings, which they called factories, and to those buildings they sent their milk, which was received by weight. Each contributor of milk to these factories received a carefully-kept account of the number of pounds of milk which he had sent to the factory, they purchased the best plant, and they obtained the best and

most educated of dairymen they could to superintend the making of this cheese. The result of this was most satisfactory. They were told that the Americans found no difficulty in carrying out this system, and, in fact, that they regard any other system as unworthy of their consideration. Now, what would be the result if they adopted this plan here? They might have many difficulties to contend with. They could hardly imagine that any tenant would like to spend his money in the erection of such factories. That was one difficulty which stared them in the face; but they would be aware that a large number of farmers who had invested considerable capital in their undertakings, and who had wives and families in that position of life in which they could not be expected to give great and laborious attention to the art of cheese-making, had to fall back upon hired dairymaids, who were not noted for the production of a high class of cheese. This class of farmers would be relieved from the necessity of having their cheese made at home. It would relieve many from this difficulty, which had to his knowledge deterred many men of large means from engaging in farming, and it would relieve those who had engaged in it from that which had been a considerable disadvantage to them. How would it affect the small holder, who had so many disadvantages to contend with? As a rule he had very inferior premises in which to make his cheese; his plant was inferior; and he had to contend and compete with those who were better situated than himself. If this system were established it would put him on an equality with the best class of dairymen. It would not only do that, but it would utilize the milk of a number of small holders which were not doing their full duty to the public, so far as produce was concerned, owing to the want of proper conveniences at home. It would bring that class of milk to a uniform and good quality of cheese, and would be a considerable benefit to the small holders of land. It would do another thing. They could hardly go into an English farmhouse, where the farmer's wife superintended the cheese-making, and not find that she was suffering materially in her health. They would find in most cases that the wife or the daughter of the farmer, who was employed in this arduous and wet occupation, suffered much from rheumatism. The factory system would, if adopted, free them from this drudgery. Then they came to the question of how it would affect the landlord, and here he could not but see that the landlord must be materially benefited. In the first place it would be an act of economy. Instead of being the possessor of a large number of dairy-farms, on each of which he had to erect a building for cheese-making, by erecting one building rightly placed, or at the most two or three buildings rightly placed, he would provide better accommodation for the purpose than had hitherto been provided; and he would be saved that large and material expenditure he had been put to in placing dairy buildings on each of his farms. But beyond that, if this system were found to add to the quality of the cheese, the improvement would add to the value of the land on which it was produced. It stood to reason that the land on which the old system was being carried on was not producing its full results because of the inefficiency of the present system. He believed that this system which he was proposing would be the means of giving a large filip to the value of land, it would benefit the tenants be they great or small, and also the landlords. If this system did not become established, the general public, who were the cheese-consumers, would have to be contented with an inferior article or look elsewhere; the makers of the bulk of English cheese would have to content themselves with producing an inferior article and taking an inferior price; and the landlord would have to rest contented to see his land not doing its full duty, and the public with not being supplied from it with such a quality of this staple food as it ought to be. England would be obliged to take a fourth-rate position among the cheese-making countries of the world. Some gentlemen there might say, "But we are satisfied with the price of cheese as it is," and point to some which fetched a high price—some as high as 78s. per cwt. But in comparing their best prices with that

of the American factory-made cheese they would find that the Derbyshire cheese fetched 78s. per cwt. of 120lbs., and if they went to the Liverpool warehouses they would find piles of American cheese at 70s. per cwt. of 112lbs.; that was equivalent to nearly 76s. of our Derbyshire weight. They found that the English champions of cheese-making, who came before them and said, "We are getting the very best price" obtained 78s. per cwt., whilst the American farmer, who made his cheese thousands of miles away, had it brought to Liverpool, where he obtained 75s. per cwt. for it, reckoning not by the smaller weight but at 120lbs. He had been in London a few days ago, and he found in a warehouse there vast quantities of American cheese which, instead of 70s., ranged from 73s. to 74s. per cwt. of 112lbs. When he said, "Why do I find such a discrepancy between that imported into Liverpool and into London?" he was told that, as a rule, provisions obtained a higher price in London than in the country, because the class of shopkeepers there were particularly anxious to get the very best quality of articles they could obtain. The fact that American cheese was selling at 74s. per 112lbs. in London warehouses, he thought spoke with great force. The gentleman who informed him of these facts in London—he did not like to mention his name; but if he did it would be known to nearly every one of them—had told him how much he had been struck by the contrast between the English and the American dairymen. "If," said he, "you go to an English dairyman and point out any defect in the result of his system of working he will turn round on you and say, 'Don't put yourself in a pet; if you don't like it you need not take it.' If, on the contrary, when I have been among the American dairymen I said, 'Your colour is not up to the mark,' or 'I can make a suggestion,' the answer would be, 'I am obliged to you for the information, and shall thank you for any suggestions you can make.'" That showed the difference between the old-fashioned English dairyman and the new-world American factory cheese-maker. The one was content to rest with the old-fashioned system, whilst the other had the intelligence to improve his make of cheese, and so place it in a higher and better position. He thought that spirit must spring up among English dairymen if they were to carry on with success this most important manufacture. With regard to the selling of the different kinds of cheese, he had in his hand a letter from a very large cheese seller, who was not a wholesale but a retail seller, who lived in the Midland counties, and who sold over his counter no less than 40 tons of cheese yearly. He had asked him what proportion the American cheese bore to the English cheese he sold, and he mentioned that they were considering the advisability of imitating the Americans in their mode of making the cheese. That gentleman wrote and said, "I have to say that I think the proposed alterations in the mode of making cheese would be attended with great success. My purchases of English cheese are confined to Warwickshire and Leicestershire; I do not deal in Derbyshire. Of these two classes of cheese I sell about 20 tons per annum, and about the same quantity of American cheese. The sale of the latter has very much increased, and if the quality continues to improve as it has done for several years past, the English factor will soon become independent of the English manufacturer, who unless he improves the quality of his cheese, must give way before the American. At the present time my American cheese is worth 70s. per 112lbs. wholesale, which is equal to 75s. per Derbyshire cwt." He also found from a very large seller at Leicester, who conducted a wholesale business, that he sold from one-third to one-half of American cheese as against Leicester and other cheese. Thus the American cheese was successfully intruding where it might be expected to be most easily defeated, in the county-town of Leicester. That seller said that "since the factory system had been introduced into America, more regularity had been attained in the cheese. It had been scientifically made, and that out of thousands of cheese scarcely one had varied in colour and quality, which could not be said of the best dairies in England." Then he came to our own county of Derby, and in a town which was gradually springing into importance, from the fact that it was situated in the heart of the mining districts of this county, he found the position of English cheese still worse. He knew no town where genuine bread and cheese was more fully supplied to the labourers than in Chesterfield. The wages which were paid into the pockets of the

miner and labourer residing in the neighbourhood amounted to more than £25,000 a fortnight, and what with the facilities afforded by the railway, which brought the miners into the town from Clay Cross, Staveley, and other large collieries on alternate Saturday-nights, when they received their pay, the bulk was spent there in provisions. It showed what the taste of the collier as regarded cheese was very clearly, for a seller in the town said, "I sell 30 tons of American cheese to one ton of Derbyshire cheese." That was a very large proportion. He regretted exceedingly that this meeting was held on Christmas-eve, the busiest day of the year for the shopkeeper. Had it not been so, they would have had the attendance of several of the largest and best known sellers of cheese in Derby at the meeting, to state what was the proportion of American to Derbyshire cheese they sold. He had asked several, and all, with one exception, said that they might fairly put their sale down as about one-half of American, as against one-half of English-made cheese. If that were the state of things in Derby, it behoved them to consider what they ought to do to ensure the milk of this large milk-producing district making the best quality of cheese, and so keep out their American competitors. He knew of no system which could meet this emergency with a greater probability of success than the American system. It was important, at any rate, that they should give the system a fair trial. No American could get his cheese from the factories landed in London or Liverpool under a charge of 8s. or 10s. a cwt. If they obtained 70s. per cwt. for it at Liverpool, it would net to the producers in America about 62s. at their own factories. That was the only point where English dairymen had the advantage of them. But still, having adopted the system of factory cheese-making, they could do it so cheaply, so expeditiously, and so uniformly good, that they were gradually assuming the first rank in the world as cheese-makers; and it, was the duty of English cheese-makers to meet the Americans as far as they could, with their own weapons, and set about, with perseverance, that system which had wrought them so large an amount of success. Mr. Smith had reminded him of an important point. A very eminent importer in Liverpool had said to them, "Well, look at the variation in the price of English-made cheese. Cheshire cheese, for instance, is declining in quality, and the bulk is very inferior. If you go to Cheshire you find a variation in the price of middling cheese from the very best, 30s. per cwt., and it is not so much less in Derbyshire." He thought there was as much variation as that in Derbyshire between middling and best quality; whereas two-thirds of the American cheese made did not vary more than 3s. per cwt., and it never varied more than 6s. It proved at once that the most was made of American milk, and it proved as satisfactorily that they did not make the most of English milk. He had a statement in his hands which showed the number of cows whose milk was made into cheese at one factory. It was called "Akerly's Cheese Factory." The whole number of cows was stated at 750. He supposed that this was the largest number whose produce found its way into the factory at any time, but the average number was 600. What we should call "shareholders" they called "patrons." Having got a certain number of patrons, they erected their building, which cost from £300 to £500. It was built of wood, and was not very elaborate, consisting sometimes of only two rooms, the one down-stairs for making cheese, and the other up-stairs for storing it. They had no steam power; they had only a steam boiler to raise their curd or water to the right temperature. A running stream of water was essential. They selected six, of their best men whom they called their managing committee, and out of them they selected two most able to go into the trading world and sell the product of their labours for the best prices they could get. This factory commenced work on the 30th of March and closed November the 16th, thus being in operation 231 days. They received during that time 1,310,540lbs. of milk, and 246,831lbs. of cheese was manufactured from it. When sold the produce realised £7,870. Each cow averaged £13; they would be best able to judge whether the cow did its duty. The patrons paid for manufacturing £987; paid for carting £71; and they appeared to have made a present to their directors of £39, possibly for travelling expenses. The worst thing against them was that they had no roads worth being called by that name. The person who had furnished him with this information described the roads as very primitive and bad, and declared that he would sooner

ride 30 miles on an English road than seven on an American one. This person also gave an instance of American sharpness. He had travelled to a factory and bought a quantity of cheese. He went at once to another at some considerable distance, hoping to purchase cheaper, and although he lost no time on the way he found when he arrived that they knew the price he had just paid, and he gained nothing by his arduous journey. He mentioned that to show how wide-awake they were. The profit left to divide in the factory, whose figures he had just quoted, was £6,772, and the names of the gentlemen were published who received the amount between them in proportion to the number of pounds of milk contributed. Those who sent a small quantity had equal advantages with those who sent a large quantity, every one being paid according to the milk he had sent, some sending under 200lbs. in the year. The cheese was disposed of in America very much as it was in England, and they had agents in London, Liverpool, and elsewhere, to whom they consigned a large quantity, and they remitted back to them the results. He believed that was a very good type of a factory. Looking at this state of things, they must come to the conclusion that these are not days to go to sleep. This factory system of making cheese had spread from the United States into Canada. Sweden was following their example, and Northern Italy was also becoming a large producer of cheese uniform in quality, which alone could be achieved by this co-operative system of cheese-making. There was no factory for cheese-making in England. The subject had been mooted in Cheshire some time ago, but no satisfactory result had been arrived at. One cheerful circumstance about the subject was that there was more cheese consumed in England and America than was manufactured by both those countries. The American consumption was about 160 million pounds, against 300 million of pounds consumed in Great Britain. Formerly the Americans did not consume cheese to any great extent, because they had not time to make it. They had got the heavy work of clearing and subduing the land to do, and had to content themselves with animal food, which required less time to produce, and the cheese they made was at first inferior. But as they overcame their first difficulties, they found the value of cheese as an article of food, and so improved their make; and so impressed were they now with its nutritious properties, that they were about to supply the army with it. Mr. Crompton also stated, in answer to a question, that a certain number of pigs were attached to some factories, and were fed upon the whey. When sold the profits went to swell the dividends of the "patrons," and was divisible upon the milk.

Mr. GREATORREX said that with an income of about £10 per cow, which he estimated would be the amount, from Mr. Crompton's statements, he would not be able to pay the rent of his farm, cultivate it in the way he did, and maintain his family. Many of the farmers in his neighbourhood—Burton-on-Trent—had not farms of 200 acres, and he would not hesitate to confess that he could not keep his family in idleness. They would be forced to do something. He would be very glad indeed to hear the opinion of his brother-farmers upon this difficulty. £10 per cow would not pay them.

Mr. NUTTALL thought Mr. Greatorrex must have been labouring under some mistake. Mr. Crompton said that £11 was left for each cow, from the price at the factory, after selling the cheese at 60s. or 62s. per cwt. That would be the price they would receive, after deducting the freight to this country, but the English farmer would get 75s. to 80s., which would give about £13 for each cow. That would, he thought, be perfectly satisfactory. Then there was whey or bacon, which would produce £2 or £3 each cow.

Mr. WEBB observed that there was also the calf.

Mr. NUTTALL was satisfied they must resort to some such system as that adopted by the Americans, for he was not satisfied to be beaten as they were now. All they had to decide was, he thought, the system to be adopted in building factories of this nature, whether by the co-operative system or by the landlords. Such a step was now as necessary as the adoption of the mowing and reaping machines. Machinery had done much to improve farming; but, so far as it had been applied to cheese-making, it had not in any degree improved its quality. He hoped there would be no unnecessary delay.

Mr. MURRAY said that the establishment of a factory, to be successful, must be on the co-operative principle. It would not succeed as a commercial undertaking, in which case the

farmers would have to pay interest on the capital. There were plenty of farmers possessed of sufficient intelligence to manage a factory. He anticipated that the landlords would make a start by providing a building, and then he saw no difficulty.

Mr. CROMPTON and others said they were all in favour of the system being carried out on the co-operative principle.

Mr. COLEMAN called the attention of the meeting to a scheme he had drawn up to apply to the first factory only. He suggested the factory be for the produce of not less than 400 cows. The consent of a sufficient number of farmers to be obtained before the erection of a factory is attempted at any place. The farmers to bind themselves to supply to the factory the whole of the milk from a given number of cows, and not to dispose of any of their milk to any one other than the factory. The agreement to be for one year only. The farmers to deliver their milk free of cost to the factory twice each day, at hours to be fixed by the managers of such factory. The produce of the factory to be divided amongst all persons according to the quantity of milk supplied, or by such other mode as the committee of management may think proper. The management to be by six committee-men, to be chosen from those farmers who supply milk to the factory, and one or more persons not being farmers, to be appointed by those who built the factory; this committee to appoint their own manager and other servants. He put down the cost of the erection of the building at £1,000, for they could not expect to build so cheaply as in America, and the plant and machinery he estimated at £200. The owner of the land on which it might be decided to erect the first factory, to find one-half the cost of the building, the other half to be subscribed by those landowners and gentlemen who may be interested in the movement. The buildings, plant, &c., to be the property of the landowner upon whose estate they may be erected; and he shall not charge any rent for the factory for the first three years, or until six other factories are at work in the county. The disposal of the produce of the factory to be left entirely in the hands of the committee of management. The promoters to guarantee the farmers against any loss which may arise in the manufacture of the cheese, should such loss be incurred through the factory and not through the committee or their manager. The promoters to provide a guarantee fund, to admit of the cheese being held in the factory until it is ready for the retail dealer, who should be the person to whom the managers of the factory must in all cases sell their produce. The produce to be sold by the cwt. of 112 lb., instead of 120 lb. as is now the case. Should any dispute arise as to the liability of the promoters, or any other matter between them and the committee of management, any such matter in dispute to be left to the arbitration of —, and his award to be final and conclusive. By adopting the co-operative system the farmers would get every penny the milk brought in.

Mr. CROMPTON said he had a letter from a proprietor in an American cheese factory, a Quaker, to one of his friends in England on the subject of cheese-making. It read thus: "Yours of the 28th inst. is to hand, and contents noted. In reply to your interrogatories I would say, the night's milk having been kept at about 65 degrees, we draw the morning's milk into the same vats, and immediately heat to 82 degrees; then add the annatto, and rennet sufficient to coagulate in about 30 or 40 minutes. As soon as the curd is solid enough to break clean over the finger, draw a curd knife, containing thirty blades one quarter of an inch apart, gently through the vats lengthwise, cutting the curd into thin slices. Wait a few minutes until the curd settles into the whey a trifle, and then cut across the vat the same as before, lengthwise. Then cut a few times lengthwise, but not to make the curds firmer than chestnuts, or perhaps kernels of Indian corn. Next put on the heat gently and equally, until the temperature rises to 88 degrees, stirring very gently in the meantime with the hands and wooden rake to keep it from settling on the bottom. Then let it stand from one half-hour to an hour. Then continue to heat just as before, until the thermometer shows 98 degrees. After this let it be quiet, with an occasional breaking up with a rake, and keeping the heat at the same point, until the whey shows decided acid, but the curd is sweet. The curd will now break dry, instead of moist and clammy; it will squeal between the teeth, and will feel hard and like shot instead of doughy. On pressing it in the hand it will not adhere in a lump, but again fall to pieces by its own elasticity. When these

phenomena appear, syphon off the whey forthwith pretty closely, and dip the curd and remaining whey into a large curd sink, and spread it evenly and thinly. After draining a few minutes most thoroughly, stir in $3\frac{1}{2}$ " salt, if in the spring, or 3" if in hot weather or fall. Let the mass cool to the temperature of the atmosphere, and put to press, pressing gently at first and harder in 15 or 20 minutes. In one hour turn and bandage and press heavily; turn the screws down again at night, and as much as you can in the morning. Remove from the presses before noon, and take to the curing-house, and oil the top and bottom. Turn on the ranges, and rub with the hand and arm every day for three weeks, greasing occasionally if they become dry and inclined to crack. After this turn every other day until sold. Keep the curing-house as near 70 degrees as may be day and night. In 20 days they will be passable; in 30 days they will be ready to ship; and in 40 days they will please the palate of lovers of fine cheese. All this is said on the supposition of having clean, sweet, pure milk at the commencement."

The Hon. E. K. W. COKE said, although he was for going ahead, he did not wish them to do so too fast. He was glad to see that Mr. Grestorex had risen and stated his difficulty, for he remembered that there were many in this county who did not see their way clear to support the factory system. He had met Lord Waterpark a few days before, and his lordship, who had just returned from America, and had heard nothing of what they were doing in Derbyshire, expressed to him his surprise that the admirable system of factory cheese-making had not been started in England. He thought Mr. Grestorex's objection had been answered satisfactorily by Mr. Nuttall. The system succeeded admirably in America, and he saw no reason why it should not answer at least equally well in this country, where they had advantages both in the climate and the roads for the conveyance of milk, for he could speak to the bad character of those in America. The question was certainly a landlord's and a tenant's question.

Colonel WILMOT said they had been told that in some cases large bacon factories were attached to the American cheese factories. Would the profits from them be divided in the same way as the profits from the cheese?

Several members answered that it would be divided in the same way, and Mr. Crompton observed that in some cases the whey was returned to the farmers in proportion to the milk they furnished.

Mr. CROMPTON said the necessity of a guarantee fund, which Mr. Coleman had urged, had also struck him, as farmers might be deterred from sending their milk to a factory in consideration of the risk which might be supposed to attend a new undertaking. He suggested that a number of gentlemen might enter into a guarantee in shares of £50 or £100, and thus make themselves responsible that under any circumstances the farmers who had sent in their milk should be paid not less than 66s. per cwt. for the cheese the milk ought to have made.

If the system was tried and turned out an entire failure, which was very improbable, then everybody who had contributed their milk would receive 66s. per cwt.; and if, on the other hand, this system resulted in a higher class of cheese, and brought a higher price, then the gentlemen who had made the experiment and contributed their milk would have the benefit, and the proceeds would be divided amongst them.

Mr. COLEMAN said he had at first thought of fixing that amount, but afterwards thought that those who produced a superior cheese would hardly be satisfied with that guarantee, but Mr. Crompton replied that the farmers must incur a little risk.

Mr. GRESTOREX said that a great deal of his objections would be removed if the co-operative system were adopted, and those who supplied the milk got the whole of the proceeds, for he acknowledged there was no more slavish work on a farm than devolved upon a farmer's wife and daughters if they did their duty; and if they did not, the husband would suffer seriously. The female portion of his household were at work in connection with the dairy, after all the rest, including himself, were at rest. In case of the sickness of the female members of his family, he had himself to turn the cheese regularly.

Mr. CROMPTON stated that the quality of the milk supplied was tested by a lactometer, and so strong a hold had the question taken on the farmers in the United States, that it was a penal offence for any one to send to the factory any milk diluted with water or dirty, or otherwise unfit for use. An Act of the Senate passed in 1865, empowered two magistrates to fine a person convicted of such an offence in a sum not less than 25 or more than 100 dollars.

Mr. MURRAY hoped that the coming summer would not pass away without a factory being established.

Lord VERNON would suggest that it would be a desirable thing to appoint a committee composed of those gentlemen who had acted in this Society for a considerable time, and especially of all those who had taken an interest in the subject. His own idea was, and had been before he came into that room, that a system of co-operative factories was the only one that was practicable, and he ventured to say that to his tenants at a rent dinner two days before. He certainly had not thought of the question of a guarantee, but he thought sufficient had been said to show that the point was deserving of serious consideration. He begged to propose that the members of the committee he suggested should be Mr. Crompton, Colonel Wilmot, the Hon. Mr. Coke, Mr. Murray, Mr. Coleman, Mr. Grestorex, and Mr. Sims, and that they report as soon in February as possible.

The names of Lord Vernon, the Mayor of Derby, Mr. C. Canner, Mr. Nuttall, Mr. Faulkner, Mr. T. Travis, Mr. Walker, and Mr. Jacob Smith having been added to the committee, the motion was passed.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—The attention of the Council of the Royal Agricultural Society having been drawn to the increasing adulteration of manures and feeding cakes, especially guano, nitrate of soda, ground bones and linseed cakes, Dr. Voelcker has been requested to submit to the monthly Council in March, June, and December, a report on the various samples forwarded to him by members of the Society, so that such report, together with the names of the dealers who supplied the substances analysed, shall, if the Council think fit, be published in the agricultural journals.

At the monthly Council Meeting held on December 8, Dr. Voelcker presented a report in accordance with the above resolution, and I now beg leave to forward you the following extracts from it, and to request that you will publish them in the next number of your paper,

I have the honour to be, sir,

Your most obedient servant,

H. M. JENKINS, Secretary.

Analysis No. 1 represents the composition of a sample of guano which I analysed for Mr. C. C. Hamilton, Harlstone.

This analysis was produced by Messrs. Perkins & Sons, Auctioneers, of Southampton, at the time of the sale. No. 2 shows the composition of a material sent to me as a sample of the bulk, bought by auction by Mr. Horace Leggatt, Brown-wich, Titchfield, Hants:—

	No. 1.	No. 2.
Moisture	15.28	4.66
*Organic matter and salts of ammonia	46.41	22.22
Phosphate of lime and magnesia (bone earth)	24.65	8.28
Oxide of iron and alumina (clay)	—	11.84
Sulphate of lime	2.28	43.62
Carbonate of lime	—	.70
Alkaline salts	8.71	1.70
Insoluble siliceous matter	2.87	7.08
	100.00	100.00

*Containing nitrogen

...	12.06	1.99	
Equal to ammonia	...	14.66	2.42

Instead of $14\frac{1}{2}$ per cent. of ammonia, as in the analysis No. 1, No. 2 barely contained $2\frac{1}{2}$ per cent. The latter further con-

tained scarcely one-third the amount of phosphates which is found in genuine Peruvian guano, and appeared to be principally made up of gypsum and a yellowish coloured loamy soil.

The next illustration of a spurious guano was furnished in a sample sent for analysis by Mr. Alexander Howden, Marston Court, Pembridge, Herefordshire, who informed me that he bought it of Messrs. G. C. Dobell & Co., of Liverpool. These gentlemen maintain that this is guano genuine as imported. This may be quite correct, for they may have imported a spurious article; nevertheless it is not a genuine guano, but a compound resembling guano in external characters, and having but little else in common with that fertiliser.

Spurious Guano sent by Mr. Alexander Howden, Marston Court, Pembridge, Herefordshire.

Moisture	11.53
*Organic matter, salts of ammonia, and water of combination	9.51
†Phosphoric acid	13.07
Lime	2.96
Oxide of iron and alumina	14.84
Alkaline salts	48.29
Insoluble siliceous matter (fine clay and sand)	100.00

*Containing nitrogen73
Equal to ammonia89
†Equal to tribasic phosphate of lime	28.53

These analytical results do not require any explanation.

The latest case was brought under my notice by Mr. H. Barneby-Lutley, Brockhampton Court, Worcester:—
Composition of a sample of Adulterated Guano marked "Feathers," sent by Mr. H. Barneby-Lutley, Brockhampton Park, September 23.

Moisture	7.27
*Organic matter and salts of ammonia	14.31
Phosphate of lime (bone phosphate)	5.83
Oxide of iron and alumina	6.48
Carbonate and a little sulphate of lime	10.98
Alkaline salts	4.35
Insoluble siliceous matters (sand)	50.86
					100.00

*Containing nitrogen	2.34
Equal to ammonia	2.84

It will be seen that this so-called guano contained only 54 per cent. of phosphate of lime in round numbers, instead of 23 to 25, the per-centage found in genuine Peruvian guano, and that it yielded not quite 3 per cent. of ammonia, instead of 18 per cent., which is the average per-centage in good guano. Adding together the worthless matters in this feathery compound, for it was nothing else but a mixture of a sandy yellow loam with a little Peruvian guano and plenty of guano bird feathers, we have no less than 75 per cent. of useless materials, and only 25 per cent. of fertilising constituents. On inquiry, I find that the "Feather Manure" was sold as Peruvian Guano at £14 a ton by a Mr. Weekes, of Bromyard, Herefordshire. Its real value cannot be put higher than £2 10s. or £3 at the most.

AUGUSTUS VOLCKEL.

TURNIP GROWING IN SCOTLAND.

The Garioch Turnip Growing Association have held their annual meeting at Inverurie, for the purpose of receiving the report of the Inspectors appointed to examine the different crops. The interest in the competition was this year enhanced by the fact that two silver medals were offered by the Highland and Agricultural Society of Scotland, to be awarded for the best crops of Swedish and Green-topped Yellow Turnips. Mr. Robert Maitland, Balhaggard, gained the medal for the former variety, and the medal for Yellows was won by Mr. William Philip, Lofthillock. The second and third prizes of the Association for Swedish were awarded to Messrs. Philip, Lofthillock, and Tait, Crichtie; and for Green-topped Yellow the second and third prizes fell to Messrs. Tait, Crichtie, and Stephen, Conglass. The following is the report of the Inspectors:—

Inverurie, 4th Dec., 1869.

In submitting the thirteenth report of inspection of turnips to members of "Garioch Turnip Growing Association," the undersigned have pleasure in stating that the crop of this year is much superior to that of last. Prospects at the early part of the season were not encouraging, the months of May and June being unusually cold, followed by great heat and drought in the month of July, and accompanied often by a scorching north-west wind. Land exposed to the sweep of the wind from that direction was under great disadvantages from that of sheltered localities. The rain of the 7th of August fell most opportunely, and from that date the growth was rapid and continuous. Although 1861 and 1866 exceed the average this year for Swedish, and the latter for Green-topped Yellow turnips, it contrasts very favourably with the two last seasons, being 4 tons 19 cwt. above the average of 1868 for Swedish, and 7 tons 3 cwt. 1 qr. for Green-topped Yellow; also 5 tons 0 cwt. 2 qr. and 5 tons 5 cwt. 3 qr. respectively above the average of 1867. For soundness and quality we do not remember a year which presented a better sample. Unless the present severe frost injure the vitality of the root, the prospects for the winter are very encouraging.

We may again call attention to the advantages of early sowing. During the last thirteen years, with few exceptions, Swedish turnips, sown not later than the 15th of May, and Green-topped Yellow previous to the 5th of June, have yielded the heaviest return.

Referring to the suggestion of the inspectors in last report, we beg to embody the report of the Committee appointed for

carrying out experiments with different artificial manures. Trials were made with different manures on three farms occupied by members of the Association. Ten poles of ground were set apart for each trial, divided in four drills of 27 inches broad and 100 yards long, which corresponds to nearly that area, each manure being apportioned to an outlay of 45s. per acre. The experimenters state that the plants of the whole came well forward for thinning, and were hoed on each farm by one individual. Millar's Manure at first took the lead; but after the rain of the 7th of August Langdale Challenge and Peruvian Guano soon presented the best appearance. The two centre drills of each test (viz., 5 poles) were carefully weighed by the Committee, and the following are the results viz.:—

	No. 1.	No. 2.	No. 3.	Average.
	tn.ct. q.lb.	tn.ct. q.lb.	tn.ct. q.lb.	tn.ct. q.lb.
Langdale Challenge	23 16 2	8 21 6	3 12 17	6 0 20
Peruvian Guano	18 4 2	8 15 13	1 20 16	15 2 24
Nitro Phospho.	17 11 0	16 16 8	0 16 12	6 1 41
Miller's Manure	15 13 0	16 15 17	1 20 15	6 2 15
Bone Dust	17 5 0	16 16 13	1 20 11	13 1 20
Somerville's Manure	16 1 2	24 15 2	1 41 3	4 2 8
Burrell's Manure	14 10 1	4 13 16	1 41 5	6 3 12
Richardson Brothers' Manure	14 13 1	20 15 10	2 8 13	6 2 8
Hill & Sons' Manure	14 7 2	24 14 13	2 24 14	0 2 8
J. B. Lawes' Manure	14 19 0	16 13 15	2 24 10	8 3 12
No Manure	—	—	7 8 0	0 —

The Secretary stated that, through the kindness of an unknown donor, an elegant Silver Cup was forwarded to him in April last, to be awarded to the manufacturer of the best artificial manure for turnips. By examination of above statement it will be observed that Mr. Langdale is clearly entitled to the cup. His manure not only stands highest on the average, but in each particular case.

JAMES MILNE.

JOHN TAIT.

JAMES PHILIP.

[Surely there is something suspicious in a prize forwarded by "an unknown donor," who makes his own conditions!—
EDITOR, F. M.]

THE INFLUENCE OF THE MOON ON THE WEATHER.

At the meeting of the Melplaiuh Agricultural Society at Bridport, Mr. John Pope, of Symondsburry, in the chair, Captain EDWARDS said, in the outset, that he was guilty of a piece of imposition in venturing to tell them what the moon had to do with the weather. He would, however, premise that he did not appear before them with any facts of his own, but simply with a series of facts which he had culled from books which he had had the opportunity of getting at. Popular opinion has in all nations and in all ages claimed for the moon a vast number of influences which do not seem to appertain to its mere physical attraction. The vicissitudes of the weather which have been supposed to follow the course of the lunar phases might be imagined, if they could be shown to have any reality, to be produced by atmospheric tides or currents arising from the moon's attraction, like the tides of the ocean. But I shall endeavour to show that there are no grounds whatever, either in theory or observation, for imputing to the moon any such influence, and that, as a matter of fact, there is no such accordance or correspondence whatever between the lunar phases and the changes of the weather. According to popular opinions and traditions the moon is responsible for a vast variety of influences on the organized world. The circulation of the sap in vegetables, the qualities of grain, the goodness of the vintage are severally laid to its account; and timber must be planted, transplanted, and felled, the harvest cut and gathered in, the juice of the grape expressed, and its subsequent treatment regulated at times and under circumstances having determined relations to the aspects of the moon, if excellence be looked for in these products of the soil. According to popular belief the moon also presides over human maladies, and the phenomena of the sick chamber are governed by lunar phases; nay, the marrow of our bones and the very weight of our bodies suffer increase or diminution under its influence. Nor is its influence limited to mere physical or organic effects; it extends its sway into the region of intellectual phenomena, and notoriously governs mental derangement. If such doctrines and opinions were limited to particular nations only prevailed or at particular epochs, they would be less entitled to serious consideration. But it is a curious fact, and one which it is difficult to account for, that many of these doctrines prevail and have prevailed among nations and peoples so distant and unconnected, that it is impossible to imagine the same errors to have had the same origin. At all events, the extent and long continuance of their prevalence entitles them to grave consideration. I propose, therefore, at present to state some of the principal facts and arguments bearing on these points, and shortly examine how far they can be reconciled with the established principles of astronomy and physics. It is believed generally, especially in the neighbourhood of Paris, that in certain months of the year the moon exerts great influence upon the phenomena of vegetation. Gardeners give the name of "Red Moon" to the moon which is full between the middle of April and the close of May. According to them the light of the moon at that season exercises an injurious influence upon the young shoots of plants. They say that when the sky is clear the leaves and buds exposed to the lunar light reddens and are killed as if by frost, at a time when the thermometer exposed to the air stands at many degrees above the freezing point. They say, also, that if a clouded sky intercepts the moon's light it prevents these injurious consequences to the plants, although the circumstances of temperature are the same in both cases. The fact observed by the gardeners and agriculturists is real, subject only to the objection that their observation of it has not been sufficiently extended. Had they seen the effects produced on clear and clouded nights which are not moonlit, they would have discovered the moon's innocence of the offence they charge her with. That these phenomena are wrongly ascribed to the influence of the moon will be easily comprehended by any one who is familiar with the physical principles which govern the radiation and reflection of heat. A clear and unclouded sky, being in fact empty space, cannot reflect back to the earth any of the heat which is radiated by bodies on the earth;

but if the sky be clouded the heat thus radiated will be reflected back to the earth in a greater or less degree. If, therefore, the firmament at night be clear and unclouded, all bodies on the surface of the earth radiating heat towards it, and receiving back no part of that heat by reflection, will lose temperature, will become colder; and this fall of temperature will become greater with bodies which are strong radiators than with those which are feeble radiators. But if the firmament be covered with clouds the heat which all bodies on the surface of the earth radiate will be reflected back to them by the clouds, and, receiving nearly as much as they emit, their temperature will be maintained. The leaves and flowers of plants are always strong radiators of heat, and on a clear and unclouded night they lose temperature continually by this radiation, not receiving at the same time any return by reflection. But if, as has been before explained, the sky be clouded, they will receive as much as they give, and their temperature will not fall. The moon, therefore, has no connection whatever with this effect, and it is certain that plants would suffer under the same circumstances whether the moon is above or below the horizon. An opinion is also entertained that timber should be felled only during the decline of the moon; for if it be cut down during its increase it will not be of good or durable quality. This impression prevails in various countries. But can there be imagined in the whole range of natural science a physical relation more extraordinary and unaccountable than this supposed correspondence between the movement of the sap and the phases of the moon? Certainly theory affords not the slightest countenance to such a supposition; but let us inquire as to the fact, whether it be really the case that the quality of timber depends upon the state of the moon at the time it is felled. M. Duhamel, a celebrated French agriculturist, felled a great many trees of the same age, growing from the same soil, and exposed to the same aspect, and never found any difference in the quality of the timber, when he compared those which were felled in the decline of the moon with those which were felled during its increase; in general they have afforded timber of the same quality. It is maxim among gardeners that cabbages and lettuces which are desired to shoot forth early, flowers which are to be double, trees which are desired to produce early ripe fruit, should be severally sown, planted, and pruned during the increase of the moon; and that, on the contrary, trees which are expected to grow with vigour should be sown, planted, grafted, and pruned during the decrease of the moon. These opinions are altogether erroneous. The increase or decrease of the moon has no appreciable influence on vegetation, and the experiments of several eminent agriculturists have clearly proved this. Pliny states that if we would collect grain for the purpose of immediate sale we should do so at the full of the moon, because during the moon's increase the grain augments remarkably in magnitude; but if we would collect the grain to preserve it we should choose the new moon. So far as it is consistent with observations that more rain falls during the increase of the moon than during its decline, there may be some reason for this maxim; but Pliny can scarcely have credit for grounds so rational, besides which the difference in the quantity of rain which falls during the two periods is so utterly insignificant as to be totally incapable of producing the effects adverted to. It is a prevalent notion in some parts of Europe that the moon's light is attended with the effect of darkening the complexion. That light has an effect upon the colour of material substances is well-known in physics and in the arts. Vegetables and flowers which grow in a situation excluded from the light of the sun are different from those in colour which have been exposed to its influence. The most striking instance, however, of the effect of certain rays of solar light in blackening a light-coloured substance is afforded by chlorides of silver, which is white, but which immediately becomes black when acted upon by the rays near the violet extremity of the spectrum. This substance, however, highly susceptible as it is of having its colour affected by light, is, nevertheless, found not to be changed in any degree when exposed to the

light of the moon, even when that light is condensed by the most powerful burning lenses. It would seem, therefore, that as far as any analogy can be derived from the qualities of this substance, the impression of the influence of the moon's rays in blackening the skin receives no support. Pliny and Plutarch have transmitted it as a maxim that the light of the moon hastens the putrefaction of animal substances, and covers them with moisture; and that if a wounded mule be exposed to the light of the moon during the night the wound will become irritated, and frequently become incurable. The answer to this is, animal substances exposed to a clear sky at night are liable to receive a deposit of dew, which humidity has a tendency to accelerate putrefaction. But this effect will be produced if the sky be clear, whether the moon be above the horizon or not. The moon, therefore, in this case is a witness and not an agent, and we must acquit her of the misdeeds imputed to her. It is a very ancient remark that oysters and other shell-fish become larger during the increase than during the decline of the moon. The fact, however, has been carefully examined by many, who have compared shell-fish taken at all periods of the lunar month, and found that they exhibit no difference of quality. An opinion is prevalent among butchers that the marrow found in the bones of animals varies in quantity according to the phase of the moon in which they are slaughtered. This question has been examined by a series of observations continued for 20 years with a view to test it, and the result was that it was proved completely destitute of foundation. Sanctorious, whose name is celebrated in physics for the invention of the thermometer, held it as a principle that a healthy man gained 2lbs. weight at the beginning of every lunar month, which he lost towards its completion. This opinion appears to be founded on experiments made upon himself, and affords an instance of a fortuitous coincidence hastily generalised. The error would have been corrected if he had continued his observations a sufficient length of time. It is a prevalent opinion that births occur more frequently in the decline of the moon than in her increase. This is also incorrect. Other sexual phenomena, vulgarly supposed to have some relation to the lunar month, have no relation whatever to that period. It is a maxim, handed down by Pliny, that eggs should be put to hatch when the moon is new. In France it is a maxim generally adopted that the fowls are better and more successfully reared when they are hatched at full moon. As these both differ I must leave you to decide which, or if either, is correct. The influence on the phenomena of human maladies imputed to the moon is very ancient. Hippocrates had so strong a faith in the influence of celestial objects, especially the moon, upon animated beings, that he expressly recommends no physician to be trusted who is ignorant of astronomy. Hence in diseases the lunar periods were said to correspond with the succession of the sufferings of the patient. Of these absurd notions there is now no relic except the term *lunacy*, which still designates unsoundness of mind. But even this term may in some degree be said to be banished as a medicinal one, and it has taken refuge in that receptacle of all antiquated absurdities of phraseology—the law—*lunatic* being still the term for the subject who is incapable of managing his own affairs. The eclipses of the moon were long considered injurious to health. In 1693 an unusual number of persons died in Italy at the time of a lunar eclipse, but an epidemic fever which was then raging had, doubtless, more to do with these deaths than the moon. An amusing anecdote is related of a village curate, near Paris, some years after, finding numbers of his flock coming to confession were so great at the approach of an eclipse that he, with a view to ease their minds, and to gain the necessary time to get through his business, seriously assured them that the eclipse was "postponed for a fortnight." (Loud laughter.) Captain Edwards then remarked that they had assembled not simply to hear his lecture but also to have a discussion. As far as his "lights" would allow him he should endeavour to answer any of the arguments that might be advanced in opposition to the opinions he had expressed.

Mr. MILLER stated that as a rule he had more lambs at the time of full moon than at the time of decline.

The CHAIRMAN thought that the answers which Captain Edwards had given to certain questions were perfectly conclusive; his arguments as to the clear night and the foggy night were conclusive beyond all debate. On many

other points, too, the captain had brought before them opinions supported by the best of authorities. So far as his own experience went he concurred in all the answers given to the opinions and maxims introduced. With regard to Mr. Miller he had the same impression as he had—that more lambs and calves were produced just at the full of the moon than were produced at the decline; but he could not support that view by any detailed experience. There were several strange facts worth notice. Some persons, for instance, would not kill a pig at certain seasons of the moon—they said that pork would not then salt. He was very pleased that the subject had been ventilated, and hoped that if any present differed from Captain Edwards they would state their reasons, and then the worthy captain would be kind enough to reply.

Captain EDWARDS said they had all seen the full moon rise, and perhaps some of them had awoken early enough to see the sun rise. They must have noticed the changes in the appearance that had taken place; they must remember that there were many optical illusions, and these being handed down to us we believed that the moon had an effect on different things. He was supported in the view which he took by opinions of high authorities. The moon, he believed, had no more to do with the number of sheep born than he had; nor had it anything to do with lunatics—as to whether they were more raving during a certain stage of the moon than at other times. It might be permitted to tell them he had heard it affirmed by a gentleman that he was a lunatic who believed that the moon had anything to do with these things.

Captain EDWARDS then proceeded taking up the second and main part of his address, the influence of the moon on the weather. The physical laws which govern the phenomena of our atmosphere and regulate the changes of the weather have always been a favourite topic of speculation. The connection of the lunar motions with the tides was apparent, long before the influence by which the moon produced the rise and fall of the waters of the ocean was explained; and this gave countenance, at a very early period, to the idea that that body had an influence on the atmosphere, if not as certain and regular as on the ocean, still sufficiently so to furnish grounds for conjecture as to changes of the weather. Ancient prognostics derived from the moon were in the first instance used as indications of the state of the atmosphere by persons too simple to trouble themselves with the philosophy of cause and effect; but when these appearances came into the hands of philosophers they were at once elevated to the rank of physical causes. Such notions were in keeping which made the moon the boundary between chance and passiveness on the one hand and the active powers of nature on the other. Although from age to age the particular circumstances connected with the moon, by which the atmospheric vicissitudes were prognosticated, were changed, still the faith of mankind in general in her influence on the weather has never been shaken. Many, it is true, may discard predictions which affect to define, from day to day, the state of the weather. There are few, however, who do not look for a change of the weather with the changes of the moon. It is worthy of remark that this persuasion is strongest by those most interested in foreknowing the weather. No navigator, from the captain to the commonest seaman, no agriculturist, from the largest farmer to the field-labourer, ever doubts the influence of new and full moon on fair weather and foul. In a work on gardening I find a chapter on the means of telling the weather, in which the supposed influence of the moon's changes has precedence over the indications of the barometer, the thermometer, and the rain-gauge; the former being characterised by the author as natural, and the latter as artificial data. Why the variations of the atmospheric pressure and temperature should be regarded as less "natural" indications of the weather than the moon the author does not say. In one of the weather almanacs lately in circulation there appeared a table professing to indicate the relation between the changes of the weather and the moon's phases, entitled "Herschel's Weather Table." The general public have fallen into a mistake in supposing that this absurd affair has been sanctioned by the authority of the illustrious astronomer whose name it bears. Whether the table in question is really the production of any person bearing that celebrated name, I cannot say; but you may be assured that neither of the eminent astronomers who have rendered the name of Herschel ever memorable has had any concern in it. As you must all know, panics of different kind have occurred in England. In

1838, the English public were seized with what I shall call a weather panic. There was at that time a rage for weather prognostics, produced apparently by an unusually rigorous and long-continued frost, which took place in the months of January and February. In one of the numerous almanacs which were then circulated, it appeared that the coldest day had been predicted by the author, named Patrick Murphey. So extreme was the public excitement at the moment on this subject that the book was actually purchased, though its price was high, by the hundred thousand. So urgent was the demand for it, that the shop of the publisher was obliged to be protected by the police, who, to keep the thoroughfare unobstructed, marshalled the expectant purchasers in a *queue*, which extended to an incredible length. Yet will it be believed that when this weather almanac was read, with the actual changes of the weather, its pretended predictions were found to fail in 17 cases out of 24! The imputed influence of the moon on the weather may be considered either as a question of theory or a question of fact. Let us consider for a moment the theoretical question. If the moon acts upon our atmosphere by attraction, as she acts upon the waters of the ocean, she will produce atmospheric tides. Thus, as there is high water twice daily, so would there be high air twice daily. The same causes also which at new and full moon produce spring tides, and at the quarters neap tides, would produce spring and neap atmospheric tides at the same epochs. At new and full moon, therefore, the air ought to be higher daily, at noon and midnight, than at any other times during the month, and, on the other hand, at quarters it ought to be lower. The barometer, therefore, should be always highest at new and full moon and lowest at the quarters; and were this the case the weather at new and full moon would be fair, while at the quarters bad weather would generally prevail. But this is not the popular opinion, the traditional maxim being that a change may be looked for at new and full moon; that is, if the weather be previously fair, it will become foul, and, if previously foul, fair. Investigations have been made at the Paris Observatory for twelve years, and it has been found that the effect of the lunar attraction on the barometer at the epochs of the high and low atmospheric tides could not have exceeded the 16-100th part of an inch—a quantity such as could have no conceivable effect on the weather. It is evident, then, that if the moon has any influence on our atmosphere it cannot proceed from any cause analogous to that which produces the tides of the ocean. But let me dismiss the theoretical view of the question and inquire as to the facts. Toaldo gives the result of observations extending at Padua over a period of forty-five years. He was himself an avowed believer in the moon's influence, not merely upon the atmosphere but even on the state of organised matter. In his memoir he has not informed us what atmospheric changes he has taken as changes of weather; and it is fair to presume that the bias of his mind would lead him to class the slightest vicissitudes under this head. But, further, in recording the changes of weather coinciding with the epochs of the phases, he did not confine himself to changes which took place upon the particular day of the phase. On the pretext that time must be allowed for the physical cause to produce its effect, he took the result of several days. At the new and full moon he included in his enumeration all changes which took place two or three days before or two or three days after the day of new or full moon; while for the quarters he included the day preceding and the day following the phases. It appears, then, that by the changes coinciding with a new and full moon recorded by him are understood any changes occurring within the space of from four to six days, while for the quarters those changes which occur within three days. It will not, I presume, require much mathematical sagacity to perceive what the results of such an inquiry would be. These are, as he found them—at every seven new moons the weather changed at six and only settled at one; for every six full moons the weather changed at five and settled at one; for every three epochs at the quarters there were two changes of weather. With such a calculation the only wonder is that the proportion he has found was not more favourable to his hypothesis. A. M. Schubler examined this question with considerable care so recently as 1830. His calculations were founded on observations extending over twenty-eight years. So far as these may be relied on it would follow that there were less changes of the weather on the average the days of the moon's

changes than on any others. A stronger argument against the moon having an influence upon the weather cannot, I think, be adduced than the following: After a cycle of 53 years, the moon being on the same day of each successive year at the same distance from the earth, her influence, so far as depends on distances, will be the same, and will produce the same effect on the weather; thus, if the state of the weather throughout the year 1816 should be examined, it ought to be the same as we are now having, and next year it should correspond with the weather of 1817; but it is well known that no calculations can be made on this data. In conclusion I will mention the absurdity, which you will all remember, of Mr. Saxby's predictions; opposed to him we have the authority of our astronomer royal, who has asserted that the coming weather, as a rule, cannot be predicted with any certainty for more than twenty-four hours. The point, and the only point of importance that remains for discussion, is whether, regarded as a mere matter of fact, any correspondence between the changes of the moon and those of the weather exists, as is popularly supposed. I think that the short examination of recorded facts which I have made proves that it does not.

Mr. LOGGIN's impression had been not that the moon did affect an actual change of the weather, but that whatever was the state of the weather when the moon changed it would continue till there was another change of the moon. Regarding the tides, it was generally believed that the spring and neap tides were affected by the moon. It seemed Captain Edwards thought that if the moon affected the water it would also affect the air.

Captain EDWARDS observed his remark was that if the moon affected the tides the atmosphere would be affected in the same way; if you had high and low tides you would also have high and low air. The truth was that the sun and not the moon affected the atmosphere.

Mr. LOGGIN: How about the change of weather?

Captain EDWARDS: It has nothing to do with the change of the moon, nothing whatever. A certain condition of weather often lasted a great number of days, and if the weather happened to change on the day of the new moon, and lasted for some time, it was put down to the moon, whereas the moon had nothing whatever to do in the matter, and there was no rule regarding it. Prayers were offered in our churches for a change of weather when rain or drought had prevailed much longer than the then state of the moon. If a new moon would bring a change of weather it was unnecessary to offer prayers. He assured them that the moon had nothing to do with it. The weather was influenced by the state of the earth and the sun. The latter it was that principally influenced the weather. It was the sun that caused certain winds to blow at certain times. In the southern latitudes there were the "trade winds," and what caused them? Why the sun and not the moon. If the sun caused the wind to blow in a particular direction was there any doubt that the sun also was the cause of the changes in the weather? He spoke modestly on this matter and with all due respect.

Mr. LOGGIN pointed out that if the moon had no influence on the tides there should be something else to account for the difference in the tides at different places. For an instance, how was it that it was high water at Bridport harbour say at six o'clock, and yet not high water at a place say hundred miles off till nine or ten o'clock? Apparently it ought to be high water at the same time at the different places, if the moon had no influence on the tides.

Captain EDWARDS said a difference of a few hours in the tides say at Bridport and London could be easily accounted for.

A MEMBER: Two-and-a-half hours.

Captain EDWARDS: Oh, it had been already reduced to two-and-a-half hours. Well, that was not difficult to explain. They all knew that London was about fifty miles from the sea; therefore the matter was easily explained. London was a long way up the river; hence the difference in the time of high tides.

Captain SWAIN remarked that there was a difference in the time of high tides at Weymouth and Bridport.

Captain EDWARDS considered this was also explained by the difference in the situation of the places. He said it was the same with the man living on the coast of the English Channel as with the man living in London, who exclaimed regarding the Thames, "What a magnificent river!" and set it down as the largest in the world. So the inhabitants of the coast

towns seemed to fancy they had the open sea, whereas such was not the case. It should be remembered that the channel gradually contracted; hence the difference in the tides.

The CHAIRMAN observed that in the early part of Captain Edwards' address reference was made to the influence of the weather on plants. They were favoured by the presence of one of the most successful gardeners in the county. The vegetables on his table were superior to any he (Mr. Pope) had seen before. He would now ask Mr. Toby to oblige them by expressing his opinion as to the influence of the weather on plants.

Mr. TOBY failed to perceive any analogy between the science of gardening and the influence of the moon on the weather. He could not see that there was any analogy at all. They had met to discuss whether the moon and the weather had anything to do with each other—whether the animals in the field, as Mr. Miller had stated was the case, were better brought forward at full moon than any other time. He knew something about the breeding of animals, which was a very important matter. When sheep had the rain constantly falling on their backs and were in a bad condition there was no chance of getting good lambs to the same extent as when there was fine, clear, dry weather. When moisture was constantly about the body there was an immense amount of evaporation which took away the power of delivery. Indeed, in many cases stimulants were needed before delivery. They all knew that in the wet, close seasons lambing was never so successful as when the atmosphere was bright and clear. Ewes before lambing should be placed under cover, and no ewe should be allowed to lamb at all in the open air.

[Indignant FARMER: Lord have mercy upon thee!]

Mr. TOBY hoped that in wet weather sheep would be taken under cover for lambing purposes. No sensible man cared about exposing his best animals to the inclement weather. Care was taken even of pigs; why not take care of valuable ewes? The speaker remarked on the superiority for breeding purposes of the hilly country of Dorset over the vales of Somerset, which were valuable for grazing.

Captain EDWARDS briefly replied. With regard to the lambing of sheep he had no doubt that more lambs were born after it was dark than by daylight. There could be no doubt of it. The weather, however, had nothing whatever to do with it.

The CHAIRMAN remarked, regarding the weather, that he placed considerable confidence in the barometer; he thought it was the best guide as to the changes of the weather. Respecting the observations of Mr. Toby, he was decidedly opposed to the theory which he had laid down, and could not join issue with him. It was generally admitted by practical men that it was a bad plan to take ewes to lamb into the house. They did not thrive well after. He acknowledged, however, that nothing tended more to lessen the strength of sheep than badly prepared food and a wet back at lambing. Nature was generally sufficient in itself for the requirements of the sheep if they were properly taken care of. It was noticeable that the fattest ewes did not always produce the most healthy lambs. The dry hills of Dorset, for breeding purposes, taking size into account, produced a larger increase of sheep than any other county in the country. The hills were dry and healthy. Somerset was more of a grazing county.

CHIPS.

SECOND SERIES.—CONCERNING MANURES.

(1). *Farmyard Manure*.—What food is to the stock, so is manure to the crops of the farm. Without the one the farmer cannot expect to maintain his cattle in health, or to fatten them for the shambles; without the other he cannot expect to add to the fertility of his soils, and thereby increase the produce of his crops; and, of all the manures at the command of the farm, that of the farmyard is the most valuable, and plays the most important part in the rôle of his cultivating processes. Nor need we wonder at this when we consider the sources of its supply—how it comes to him from the stock he feeds, so that the circle of operation is complete; the crops which feed the cattle, the cattle which give the manure, and the manure which in time gives fertility to the soil which yields the crops; and further, from the fact that this manure contains in itself all the elements of fertility which the plants require. True, that these elements are small in bulk as compared with the bulk of the manure in which they are present; thus, in every ton there is no less than some fourteen hundredweight of water, from four to six hundredweight of solid matter of inferior value, and only from two to half a hundredweight of fertilizing constituents. But we are inclined to think that we too readily take the purely chemical truths which these facts indicate into consideration, and lose sight of what may be a great truth, and which will go to account for the high manurial value which farmyard dung possesses. For, independently of the fact that the manure exercises a most important mechanical influence upon the soil, opening it up most usefully in the case of heavy soils, and even in the case of light ones to the ameliorating influences of the light and air, we are not sure that the large per centage of water which the manure is sure to contain is to be set aside as useless, not reckoning it as part of the fertilizing value of the manure. As water pure and simple it cannot be of value in this respect; but it may be, and we

are inclined to think it is, a very different matter when combined with other constituents. In the absence of positive information as to what the circumstances of the combination really are, conjecture is as sound and is as likely to be as safe on the side of the supposition that the water of combination plays an important part in the manure, as that it does not. The point is one, assuredly, which demands a close investigation, if, indeed, this investigation can ever be properly made when so much is uncertain. In fresh farmyard manure the ammonia is present in a very small proportion, the major part of the nitrogen being present in the state of insoluble, nitrogenous materials; these, however, as the dung increases in rottenness increase in solubility, and the per centage of ammonia is raised. Hence is deduced the recommendation that in order to prevent the escape of the volatile products, the manure should not be exposed to the air, but kept covered up. We have in this journal given plans of covered manure pits, which are, beyond all question, appliances most useful on a farm, and which should have always a place in all farm-buildings. These pits should not only be covered at top, open of course at the sides; but the bottom part, in which the manure lies should be made perfectly water-tight, so that the liquid shall not be suffered to escape and be lost. This liquid will best be preserved in a tank which communicates with the bottom of the pit, and from which, from time to time, it may be pumped up. Some prefer to pump the liquid-manure from the tank on to the heap, allowing it to soak through the mass on its way a second time to the tank.

As this is the season for carting out manure in the stubble-fields, we shall glance very briefly at the way in which this should be left. The point is much disputed as to whether it is best to plough the dung into the soil in the autumn, or to spread it on the surface of the same, allowing it to lie all the winter and be ploughed in at spring-time. We put out of court altogether the practice of

cutting the dung into the fields, placing it in heaps, and then allowing those heaps to lie all the winter, or at least a large portion of it. The practice of spreading the manure on the soil and allowing it to lie all winter, ploughing it in in spring, meets with the approval, not only of practical men (whose opinion is worth listening to, if not of following), but also of high scientific authority. One of our agricultural *savants* who recommends this practice, maintains that, being washed into the soil by the rains, it is much more uniformly distributed than by ploughing it in. Now, before being washed in, it may happen (as in practice, in fact, it does happen) that a long tack of dry weather takes place after the manure will be spread on the surface; and in this case the manure is placed in the very worst position for returning its fertilizing constituents, for the ammonia must be distributed in the air. That it is so, our olfactory sense tells us in crossing a field treated in this way. If we are told to keep our manure in covered pits, in the farm steading, in order to prevent the ammonia from being dissipated in the air, how can we reconcile this with the advice to spread it out upon the surface of our fields, and allow of its exposure for weeks, if not for months, in the action of the air? For our part, we would rather not trust to the matter of fertility present in the dung being washed into the soil. We would then be inclined to allow the general practice of ploughing in the manure to the soil as shortly after it is spread on the surface as possible to be persisted in as the safest. Where manure during the frosty weather of winter months, when the fields are hard-surfaced and the roads good for cartage, is carted on to the field, we would most strongly urge the plan to be followed of making a manure-pit or pits as closely in accordance with these principles we have indicated. We should even advise the farmer to go to some trouble and some expense in preparing a pit for the manure, if not to make a special one. At all events the site of the pit should be carefully rammed close, if not puddled with retentive clay, to prevent the liquid, which is of high manurial value, being allowed to soak away into the soil. To secure this the best way will be to make an excavation of some 18 to 24 inches deep, with sides and ends sloping inwards towards the centre, ramming the soil well up, or, as above stated, puddling it. It will be a good plan to spread a bottom-layer of compost-manure, into which the liquid will soak; this being in spring thoroughly well-mixed with the manure placed above it. The foundation being thus prepared, the manure may be carted to the pit, from the steading, and laid in it in uniform layers. If the heap cannot be finished at once, each time it is left a thin layer of soil should be spread over the whole surface. When the heap is finished, it should be properly shaped ridge fashion, and the surface covered with soil.

CONCERNING STOCK.

Percentage of Flesh-formers in Cattle Foods.—We have given a statement of the per-centage of water, starch, and oil in foods; we now do the same with regard to the flesh-formers, dividing the foods into the classes of, 1st, cereals; 2nd, leguminous seeds; 3rd, straws; 4th, roots; 5th, leaf crops; 6th, grasses; 7th, refuse of the cereals; and 8th, artificial foods. (1) *Cereals*: Wheat 14.6, barley 12.8, oats 17, rye 13.83, Indian corn 12, buckwheat 8.6. (2) *Leguminous Crops*: Beans 24 (taking the form of caseine), peas 23.4, lentils 26. (3) *Straws*: Wheat straw 1.79, oats 1.63, barley 1.68, rye 2.29, beans 6.79, peas 12.55. (4) *Roots*: Swedes 1.443, white turnips 1.143, mangolds 1.64, potatoes 1.4, parsnips 1.21, carrots 0.6, kohlrabi 0.227. (5) *Leaf Crops*: Cabbage 4.75, cauliflower 3.61 (leaves), 8.84 (flowers), mangold leaves 1.76, turnip leaves 2.45, swedes 2.08. (6) *Grasses* (dried state): Red clover 3.60, white

ditto 4.52, yellow 4.48, Alsike ditto 4.82, lucerne 4.40, sainfoin 3.51, vetch 3.56. The above in the natural state as cut: Red clover 18.64, white ditto 28.31, yellow ditto 20.00, Alsike 20.69, lucerne 16.56, sainfoin 15.50, vetch 20.00, sweet-scented meadow or vernal grass (*Anthoxanthum odoratum*) 2.00, crested wagtall grass (*Cynosurus cristatus*) 4.13, cock's-foot (*Dactylis glomerata*) 4.96, rye-grass (*Lolium perenne*) 3.87, Italian rye-grass (*Lolium italicum*) 2.45, grass from water meadow 2.78, meadow hay 10.69. (7) *Refuse of the Cereals*: Bran 13.80, malt-dust and malt-coombs 25.62. (8) *Artificial Foods*: Linseed-cake 29.75, rape-cake 29.53, cottonseed-cake 41.25, linseed-cake (average quality) 28.21, Patent cake 20.66, Company's cake 24.62, ditto 65.87, ditto 46.31, ditto meal 38.44, palm-nut meal 18.01, compound nut-meal 31.81, Cruchley or greaves-meal 24.75.

Treatment of Ailments of Stock.—Commencing our brief notes upon this important department in the care of stock with the calves, we find that the first complaint to which they are subjected is the souring of the milk in their stomachs. This, if not prevented or cured, gets frequently to such a point that a *post mortem* examination will show a mass of curdled milk so hard that it may be cut with a knife. A very eminent breeder and rearer of stock uses, as a preventive means, a dose to the calf as soon as dropped and before it is allowed to suckle the cow, composed of rhubarb, magnesia, and castor-oil—a teaspoonful of each. If the disease or complaint has set, the same medicine with the omission of the castor-oil is given, but twenty grains of the "grey powder" is substituted for the latter, the doses being repeated every six hours. For attacks of the "scour," a complaint to which calves in a more advanced stage are liable, a dose of a quarter-of-an-ounce of nitre, ditto of ginger, and six ounces of Epsom salts will be useful; to this we would recommend the addition of a teaspoonful of sulphur. A gaseous fluid has been found in many instances an admirable remedy for the scour. A third complaint to which calves are liable is the "huak," which is accompanied with a short hacking cough, and generally attacks the animals when about nine months old. The complaint is caused by small worms or parasites attacking the wind-pipe, and, if allowed to go on, ultimately the lungs. Tar applied daily to the nose of the animal in small quantity will be found a cure in the majority of instances. The hoose or "catarrh," to which calves are very liable, often commits great ravages amongst them. As soon as the disease appears attention should be paid at once to the animals, "the first cough heard," says an authority, "should be the signal for the display of unceasing vigilance on the part of the attendant." If at the commencement of the disease remedies are applied, it will soon likely be checked. A very simple remedy in the first stage is a little nitre, given at night in a warm bran mash; two drachms will be enough, and a little sulphur will be an improvement—say a teaspoonful. When these are administered, it is necessary to guard against the animal taking cold, to which it is a little more liable than usual when these are given. Should the cough not yield to this simple treatment, one a little more energetic will be required, as small doses of tartar-emetic and digitalis. Along with medicine careful attention should be paid to maintaining a uniform temperature in the calf-house, and to have this kept thoroughly clean; the food should be of the best quality, and it should be given rather at frequent intervals in small quantities than at longer intervals and in larger quantity. "Experience," says an able authority, "will teach the farmer that these chest affections in cattle often, and speedily, assume a highly inflammatory character, and that they must be conquered at first or not at all."

Of quarter-ill, "black-quarter," or "joint-murrain," an able authority states, inflammatory fever but indicates the nature of the malady. So sudden, he says, are its visitations that the beast in perfect health to-day, may be found drooping and out of sorts to-morrow. The symptoms are too well known to be here given, the prominent ones being great languor, with unsteadiness in the hind-quarters when walking or moving, which the animal has a great dislike to do; the breath is heated, the pulse quick, the muzzle dry, and the disturbed anxious look of the eye shows how uneasy the animal is. When an animal is seen to be attacked, get it, if in the field, housed as soon as possible, and supplied with good litter, in a clean, well-ventilated stall. The animal should then be bled, and a purge—say of Epsom salts—given to it. If a change for the better takes place, the symptoms not increasing, doses of nitre, tartar emetic, and digitalis should be administered twice or thrice a day. If the joints become swelled, hot water fomentations should be at once applied, and afterwards well rubbed, but gently, with a liniment made of camphorated spirits of wine, liquid ammonia, and salt. In the worst stages of the disease ulcers may break out in various parts of the body, but these will be especially in the mouth. No better application to these can be made than sulphurous acid (*not sulphuric acid*): this will at once allay the inflammation, and stop their spreading. One of the most valuable preventives of quarter-ill is good feeding, with carefully-cleaned and well-ventilated housing. Another preventive, highly

praised by eminent men, is the passing of a "seton" through the dewlap of the calf. In feeding, oil-cake should form part of the food, as this substance tends to keep the bowels regular. A dose of nitre, ginger, and sulphur, with Epsom salts, as already named, should also be given to the animals occasionally; this will serve to keep the bowels regular, and it has moreover a remarkably good influence upon the general health of the animal: indeed, of all the medicine used for stock, we are inclined to consider this as the most valuable. As to the use of setons, Mr. Youatt believes them to be of great advantage; they excite inflammation in the neighbourhood of the diseased part, and thus cause a determination of blood, to a greater or less extent, to this new seat of irritation. They are useful in both acute and chronic inflammation of the respiratory organs. For young cattle, rapidly thriving, and placed in pastures perhaps a little too luxuriant, permanent setons are highly beneficial; they act as a salutary drain, and prevent that accumulation of the circulatory fluid which is the usual cause of inflammatory fever and other fatal complaints. The seton is passed through the loose skin of the chest, but not too far down, so as to enable the animal to lie down with ease. The seton is made of twisted cow's tail hair, of the thickness of a finger, and is provided with a button of wood at one end, and a knot at the other, and it should be saturated with turpentine before insertion. The seton should be pulled from one end to the other once every day.

THE CENTRAL FARMERS' CLUB. CONTINENTAL FARMING AND PEASANTRY.

APPENDIX TO THE PAPER READ AT THE FARMERS' CLUB BY MR. JAMES HOWARD, M.P.

The answers to the following questions were given either by letter or *visâ voce*, and are from gentlemen of experience and position. The information received has been much condensed; nevertheless, it is hoped that the facts given may not be without interest.

Question.—*Is the land in your immediate district divided into large and small farms? If so, what is considered a large and what a small farm, and which form the greater proportion?*

Answers:—

Monsieur J. Leclerc, Inspector-General of Agriculture, Belgium.—The following table indicates how rural property is subdivided in Belgium. In the year 1856 there were farms not exceeding—

1½ acres.....	247,551
1½ to 2½ acres	70,413
2½ 12½ "	165,933
12½ 25 "	48,737
25 37½ "	17,432
37½ 50 "	9,153
50 62½ "	5,590
62½ 125 "	9,408
125 250 "	3,329
250 and upwards	1,004

Total number of farms..... 572,550

This total comprises 6,507,590 acres, of which 3,558,632 acres are cultivated directly by the owners, and 2,948,958 acres by tenant-farmers. The following is the mean extent of the farms in the various provinces:

Antwerp	12 acres	Liège.....	11½ acres
Brabant	8½ "	Limburg ...	17 "
W. Flanders.....	9½ "	Luxemburg	28 "
E. do.	6½ "	Namur	18½ "
Hainault	8 "		

Average for the whole country, 11½ acres.

Landed property in Belgium tends to subdivision, This is

the inevitable consequence of legislation which gives to each child the right of claiming one share of the paternal estate, and also is a consequence of the increase of public wealth. Many people who have acquired wealth in business wish to become landed proprietors.

Baron Peers, President of the Agricultural Society of West Flanders, Belgium.—In the two provinces of Flanders property is much divided. There are a few large and many small farms; most of the latter are let without buildings. The majority consist of 1½ to 20 acres; the tillage, &c., being done by the help of cows.

Herr Joest, of the Rhenish Beet-root Sugar Company, Prussia.—Land is much divided; 400 acres is considered a large farm; small farms 27 to 34 acres. Small farms predominate.

Baron Elsnar von Gronow, member of the Royal Prussian Board of Agriculture, Silesia.—Land over the whole of East Prussia is divided into great and small properties. There were in Prussia in 1858 farmed properties under 3 acres 871,922, properties from 3 to 13 acres 521,590, properties from 13 to 180 acres 359,897, from 80 to 360 acres in the country 14,063, from more than 360 acres 14,082. The assessment of landed property in 1865 showed—

5,518 properties of £150 to £300 annual value	
2,600 do. £300 to £450 do.	
1,971 do. £450 to £750 do.	
689 do. £750 to £1,500 do.	
108 do. £1,500 do.	

In 1865 were 291,014 properties in the townships
" 1,503,434 " parishes
" 22,467 " hands of the gentry.

If you take the taxed revenue 30 times, it will represent the real value of the property. The morgen, or Prussian acre, pays in my neighbourhood on land of middle quality about three thalers a year (5s. 5d. per acre).

Dr. Emil Perels, Professor of Agriculture at the University of Halle, Prussia.—Most farms are in the hands of independent owners; hired farms, with the exception of the State domains,

are exceptional. By a large farm is mostly understood one of 600 English acres. The largest estate in my neighbourhood is Saltzünde, with a superficies of 6,000 acres, the smallest (peasant's holding) about 12 English acres. In the Prussian kingdom the peasant holdings preponderate.

Monsieur Edouard Lecouteux, landed proprietor and editor of the *Journal d'Agriculture Pratique*, France.—In the district of Sologne large estates predominate. There are domains of 5,000 acres, but they tend to subdivision. Estates of about 700 acres are the most easily disposed of. The large estates are let in farms of 350 to 500 acres. There are many small holdings of 30 to 50 acres, and others of 2 to 12 acres.

Monsieur Gustave Hamoir, agriculturist, Valenciennes, France.—Landed estates here are very much divided. There are few large proprietors. All are let on lease, and, if large, are often distributed among several tenants. Twenty-five acres is considered a large extent. Ten acres may be considered as the average. A large number are only $1\frac{1}{2}$ acres. It is a rare exception for the landed proprietors to farm their own estates. A great number of farmers have a fourth or more of their land their own property, and hire the rest on lease. There are some farms of 450 to 650 acres; but the mean size of a farm must be considered $3\frac{1}{2}$ acres, and such farms may be considered to predominate.

Monsieur de Pimpin, manager of the farms of La Brèche, the property of Monsieur Cail, near Tours (Loire), France.—Except upon the banks of the Loire, where the plots are very small, landed property is not much subdivided in Touraine; many farms of more than 2,500 acres may be counted; ordinary farms are from 125 to 200 acres; the largest are 4,000 acres in extent, and the smallest 125 acres. The small farms, of which a good many frequently belong to one proprietor, predominate.

Monsieur Maurice Lapointe, farmer, near Metz, France.—Amongst 100 farms in this district there are 30 of from 125 to 200 acres, 70 from 200 to 350 acres, and 10 exceeding 350 acres. The largest farm is from 375 to 400 acres, and the least 50 acres: holdings of a less extent are not considered farms. I consider the mean size 200 to 350 acres.

Monsieur Bovet, agriculturist, Neuchâtel, Switzerland.—Land is much divided. Farms in a ring fence are very rare, except in the mountains, where they are the rule. In Western Switzerland farms of $12\frac{1}{2}$ to 25 acres are considered small, 25 to 75 medium, and 75 to 250 large. Larger than 250 acres are very rare, except in the mountains. The greater proportion of farms are small.

Mr. Whitmore, agricultural engineer, Bologna, Italy.—In this district there are not the large properties or farms as in England, nor the very small ones of Ireland, but instead, medium farms. There are a few large holdings, but not counted as in England, but rather several small farms united. Each farm is of a size to be cultivated by one family of labourers; the number of persons in a family will be about 12. In this district a farm such as is above intended will be about 35 to 50 acres in extent.

From an agriculturist in Austrian Galicia; communicated by Professor Fuchs, Perpetual Secretary of the Imperial Agricultural Society of Austria.—The land in my immediate neighbourhood (district of Cracow) is divided into large farms of 120 to 450 acres, and peasant farms of 3 to 45 acres. In my district the largest farm is 450 acres, and 120 acres the least. Peasant proprietors farm 3 to 45 acres. In my environs farms consist mostly of 300 acres arable and 45 to 75 acres pasture. For each farm of 300 to 375 acres there are in proportion 30 to 40 peasant farms.

From an agriculturist in Austrian Silesia; communicated by Professor Fuchs, Vienna.—Farms are seldom let on hire. They vary in size from 450 to 750 acres. The largest is 1,750 acres, the smallest 120 acres. Farms are generally from 450 to 750 acres in extent.

Herr Nitch, steward of Count Magni's estate of Strassnitz, in Moravia; communicated by Dr. Fuchs, Vienna.—The land is all in large farms. Above 3,000 acres is considered a large farm, and under that extent a small one. The largest farms are 30,000 acres, the smallest 900 acres. In Moravia the larger farms predominate.

Herr Nicholas Fehér, farmer and agricultural engineer, Hungary.—There are hired farms in this country as large as 325,000 acres, and some as small as $7\frac{1}{2}$ acres. There are some landed proprietors who own as much as 600,000 acres,

What is about the average rent of large farms and of small ones, land say of medium quality? If the land in your district is of three qualities, perhaps it may be as easy for you to give the rents of each.

Monsieur J. Leclerc, Belgium.—The average rent of farms in the various provinces in 1856 was:

Antwerp, 24s.	per acre.	Liège, 32s. 4d.	per acre.
Brabant, 32s.		Limburg, 19s. 10d.	
W. Flanders, 26s. 8d.	"	Luxemburg, 14s.	"
E. Flanders, 34s.	"	Namur, 20s. 4d.	"
Hainault, 35s. 2d.	"		

Average rent for the whole country, 26s. 2d. per acre.

Rents have increased considerably during late years in those parts where agricultural industries have been established, chiefly sugar factories. There are in the neighbourhood of Brussels farms which are let at the rate of 58s. per acre. The rents of small farms, for which there is much competition, range generally from 40s. to 48s. per acre.

Baron Peers, Flanders.—For third class land, in large farms, farmers pay 21s., for medium quality 29s., and for the best land 38s. 6d. per acre. Small farms let for 29s., 40s., and 45s. per acre for land of similar quality to the above.

Herr Joest, Cologne.—The average rent is 31s. 6d. per acre, both of large and small farms. The different classes of land are brought almost to one standard.

Baron von Gronow.—The Prussian landowner farms mostly himself, and small landowners do not let farms; only the State and great landholders let land. The greater landholders sometimes let small plots of arable land to the smaller landholders or farmers, or to the labourers. In my own case I let about 360 acres in pieces of $2\frac{1}{2}$ to $7\frac{1}{2}$ acres, at a rent of 25s. per acre for the best quality, and 7s. 6d. for the worst. Land is divided into six classes for taxation purposes.

Dr. Perels, Prussia.—The rents of farms, medium quality of soil, varies much; the extreme limits are from 20s. to 75s. an acre.

In general the small holdings are not let as farms, the owner farms himself. Small lots are let at 30s. to 35s. per acre. The rents may be classified as follows: Soil, first quality 50s., second 35s., third 25s. per acre.

Monsieur Lecouteux.—The rent of large farms is from 4s. 10d. to 8s. per acre, the minimum rent of small farms is 8s. Generally, however, the rent is paid in produce on the "métayer" system.

Monsieur Hamoir, France.—The average rent of land is 72s. per acre. Large and small farmers compete for the land. The very small farmers pay a higher price, because they have to do with small plots, and do not offer so good a guarantee to the proprietor. The difference in the rent of the various classes of land does not bear any analogy to the natural quality of the soil, as high farming based upon root crops has brought all land almost to the same level.

Monsieur de Pimpin, France.—In the north of Touraine the rent of the land is about 3s. 3d. to 4s. an acre, whilst in other districts of the department rent varies from 13s. 9d. to 25s. 6d. an acre. The general rent for small plots of medium quality is 9s. 6d. per acre. First quality land is let at 25s. 6d. per acre, second ditto at 12s. 9d., third ditto at 8s. in the good part of Touraine. In the north, however, the rents are: First quality 6s. 5d. per acre, second ditto 4s. 9d., third ditto 2s. 8d.

Monsieur Maurice Lapointe, France.—First class land lets at 19s. to 22s. 6d. per acre, second ditto 16s. to 19s. 6d., third ditto 13s. to 16s. In this department there are farms let from 33s. to 35s. an acre, and others at 9s. 6d. to 11s. 6d.

Monsieur Bovet, Switzerland.—Good land lets for 40s. an acre, medium 25s. 6d., poor 16s. Pastures are let according to the number of cattle they will carry. The difference between the rent of large and small farms is unappreciable.

Mr. Whitmore, Italy.—The average rent is about 32s. per acre. It is all good land, and varies little in quality.

Dr. Fuchs, Austria.—(From Austrian Galicia).—The average rents of the larger farms in Austrian Galicia, second to third quality soil, is 11s. to 14s. per acre. The rent of small plots of $1\frac{1}{2}$ to 3 acres ranges from 32s. per acre for best quality to 5s. for the poorest. Peasant farms, the property of former serfs, are held by the class, and are not let.

Dr. Fuchs, Austrian Silesia.—Rent varies from 15s. to 60s. per acre.

Dr. Fuchs, Moravia.—21s. 4d. to 25s. 6d. per acre; 19s.

2d. to 22s. 4d. First class 32s. per acre, second class 22s. 4d. to 25s. 6d., third class 16s. to 19s. 2d.

Herr Fehér, Hungary.—Rents range from 2s. 8d. to 8s. per acre. The proximity of the railway has a great deal to do with the value.

At what price can land of medium quality be purchased in large lots? and at what price in small lots?

Monsieur J. Leclerc, Belgium.—Here follow the average selling prices of land in the various provinces in 1856.—

	per acre.		per acre.
	£ s. d.		£ s. d.
Antwerp ...	47 17 6	Liège ...	57 10 8
Brabant ...	68 17 8	Limburg ...	34 18 6
W. Flanders ...	50 19 2	Luxemburg ...	16 13 10
E. do. ...	69 11 8	Namur ...	39 8 6
Hainaut ...	70 14 8	Average for the country ...	50 14 8

On account of the situation, or of particular circumstances, land frequently reaches the value of £112 to £160 per acre.

Baron Peers, Flanders.—Lands of medium quality can be purchased at £56 per acre, that is, in lots of 125 to 150 acres. In small plots of 5 to 15 acres £64 to £72 per acre is realized.

Herr Joest, Prussia.—From £50 to £75 per acre is the price of land in large lots; in small lot £30 to £37 10s. per acre.

Baron von Gronow, Silesia, Prussia.—Land in large lots fetches from £15 to £20 per acre with the farm buildings, &c., and in small lots £25 to £37 10s. per acre without buildings, &c.

Dr. Perels, Prussia.—The selling price of land varies considerably according to locality. It ranges from £37 10s. to £75 per acre.

Monsieur Leconteux, France.—Land in large lots is sold at 64s. to £3 per acre.

Monsieur Hamoir, France.—Large lots £96 per acre, and in small £144 per acre. When there has been a succession of good crops for several years, and the farmer has saved money, the price of small lots is considerably augmented, because the ordinary farmer does not and will not appreciate any other investment than land, and buys therefore at any price when there is a possibility of doing so. I have known land sold at £192 per acre.

Monsieur de Pimpin, France.—The price of land varies from £8 to £20 per acre, according to the quality of the soil and the position of the property. £28 per acre is realized for small plots. When higher prices than these are paid it is owing to special circumstances.

Monsieur Lapointe, France.—Large plots £20 to £40 per acre; small ones £24 to £48. Some farms sell for as much as £192 to £160 per acre.

Monsieur Bovet, Switzerland.—In large farms £24 to £32 per acre including the farm buildings. Mountain and forest-land £3 6s. to £5. Small farms sell for £48 to £56 per acre. Vineyards fetch from £300 to £320 per acre.

Mr. Whitmore, Italy.—Large farms can be bought at about £20 per acre, and small one at about £32 10s.

Dr. Fuchs, Austrian Galicia.—Large farms of medium quality can be bought at £7 to £8 per acre.

Dr. Fuchs, Austrian Silesia.—In large plots from £20 to £25 per acre. In small plots from £25 to £30 per acre.

Dr. Fuchs, Moravia.—Large plots 25 6s. 8d. to £13 6s. 8d. per acre; small plots £8 to £16 per acre.

Herr Fehér, Hungary.—Large estates sell from 53s. 4d. to 93s. 4d. per acre, according to their position. Small farms 54s. 4d. to £20 per acre, according to situation.

Are the small farms in your district the property of the occupiers, or do they rent them? What is your opinion upon the question of peasant or small farmers? Is it better for their own interests and those of the country that they should be the owners or simply the tenants of the soil?

Monsieur Leclerc, Belgium.—The number of small farms let to tenants or farmed by their proprietors is about equal. In my opinion it would be better for both small and large farms to be worked by the proprietors.

Baron Peers, Flanders, Belgium.—Both small and large far-

mers are generally tenants, few are proprietors of the land they occupy. There is nothing worse for the small as for the large farmer than to be proprietor of his farm. When he buys he has almost always to borrow a part of the purchase money to pay a heavy interest, and has to be careful in payment. At his death, if there are many children, they sell. The expenses come to from 15 to 18 per cent.; in a word, those who are well advised invest their money, and the greatest number do this. In this manner they have their money when they want it, and can meet all eventualities. However, our farmers are not always ready to buy. They often enter upon a farm of from 100 to 125 acres, with a capital of £40, whilst they ought to have £80 to £100. It is only by dint of economy and privations that they get round, and this at the end of 30 or 40 years.

Herr Joest, Prussia.—Farms are mostly the property of the farmers. Prosperous farmers are to be preferred to poor proprietors, but many owners are said to produce a rich country.

Baron Elmer von Gronow, Silesia, Prussia.—I think you get a more steady population if every one owns the land he farms. In eastern Prussia there exists no class of persons who would farm a very small property, so I had never occasion to compare the results. For the State and the great landowners it is better to let the farms out to farmers with intelligence and capital, but a man of intelligence could not subsist on a smaller farm of middle quality than 130 to 200 acres.

Dr. Perels, Prussia.—The small estates are as a rule the property of the farmer; it is an exceptional case when they are hired. As a general rule, it is considered in this country more advantageous when the farmer owns his land. An independent peasant proprietor is to be preferred to a tenant farmer.

Monsieur Leconteux, France.—The small farms are worked by farmers or "métayers." The position of proprietors is the best in the world for the peasant, but on the condition, however, that he has sufficient money to work his land. Generally the peasants are possessed by the *démou* of property, they buy too much land, and have no capital to work it with.

Monsieur Hamoir, France.—Very few of the small farms are completely the property of the occupier; it is quite the exception. It were certainly preferable that the small farmer should not be a proprietor or landowner at the price he pays. The interest of his money invested in ordinary securities would permit him to hire, even at a high rate, double the quantity of land that he could hold as an owner, but he does not enter upon this path, because of his ignorance and fear of investing money, and for another fear at least as serious, that of the short duration of leases, at the end of which he dreads to be ousted for some competitor.

Monsieur de Pimpin, France.—As a rule small farms are not the property of occupiers; they are hired for a money rent. This system of letting equally prevails in the north of Touraine, where the proprietor gets from 3s. 2d. to 4s. an acre; in the south, contrariwise, "métayage" prevails. The system of letting land for money in the north of Touraine is bad in this sense, that the farmers for the most part are destitute of the requisite knowledge, nor have they capital enough to work the land they rent. In order to live they have to work upon the feelings of the landlord by inducing him to take a low rent whilst they exhaust his soil, for they never manure it; the result is a state of non-progressive agriculture, and these farmers are constantly complaining. To insure progress where neither the rent nor the selling price of the land is high, there must be either farmers possessing both money and intelligence, knowing their business in fact, or else the landlords must farm themselves.

Monsieur Lapointe, France.—The small farmers though not numerous are in easy circumstances. The owners of small farms who wish to cultivate themselves, when they have money, often let their own land and cultivate a larger quantity, which they hire on lease. I think for the most part they would find it to their advantage to employ their capital in the cultivation of a less extent of land.

Monsieur Bovet, Switzerland.—They are generally farmed by the owners. We think it is better they should be owners; it is a great guarantee for the fixity of social order. For high farming it is a different matter, though for the last few years the example of the large proprietors and neighbouring farmers has exerted a salutary influence. The class of farmers

in this country are, as regards the majority, men belonging to the class of small proprietors.

Mr. Whitmore, Italy.—They are nearly all let out to the labourer on the "métayer system," the proprietors residing in the adjacent towns. The general opinion in this country is, that so far as the labourers or their families are concerned, the "métayer" is the best system.

Dr. Fuchs, Galicia.—The small farms are the properties of the peasants. The farming of the peasants is in a very poor state. There is no industrial manufacture in this district, consequently there is no capital; if there were capital the farming would be better, and it would also be to their advantage under such circumstances to be owners of their land.

Dr. Fuchs, Moravia.—Small farms are the property of the occupier. I think it would be better if they were tenants.

Herr Fehér, Hungary.—Scarcely one-tenth of the land is let on hire. The land is the property of the occupier. I think it is every way better for the peasant or small farmer to cultivate his own land rather than that of another.

Is land let by the year or upon lease for a number of years; if upon lease, for what term of years? Are the leases verbal or in writing, and is it usual for them to contain covenants or stipulations binding the tenant against overcropping the land or cropping it in a particular way?

Monsieur Leclerc, Belgium.—The land is always let on lease. The duration of the leases is generally nine years, with the option of withdrawal at the end of three and six years; but some intelligent land owners are beginning to understand that it is to their interest to give longer leases, and there are already some of 12 years. Agricultural societies aim at this amelioration. In some parts of the country the outgoing tenant has a claim to an indemnity on the part of the incoming tenant for manure in the land and the improvements he may have made; this is an excellent system, and gives much security to the farmer. Agricultural societies endeavour, also, to make this custom the general one. Leases are always made in writing, and they often contain restrictions. These last, however, are disappearing as the leases become longer, and as the principle of paying the outgoing tenant is adopted.

Baron Peers, Flanders, Belgium.—All the land is let on lease; the general term is 9 years; some for 12, 15, and 18 years, but these are the exception. There are few verbal leases, almost all are written. Frequently they are made out by a notary. Nearly all are private agreements. All contain rigorous stipulations of annulling, or heavy penalties when the farmer exceeds his powers. He ought to cultivate like a good father of the family, put on manure, lime, and plough and hoe properly. The last year of his lease he must not, in a farm of 125 acres, grow more than 5 acres of buck-wheat, 5 acres of oats, and other exhaustive crops. At the end of his last harvest, he receives, according to estimates, from the incoming tenant, the price of the farm-yard manure and former dressings; even for the liquid manure he receives a value. The farmer is charged with the repairs of the hired buildings, painting, &c.

Herr Joest, Prussia.—Land is let on leases for 3 and 6 years; but as a rule leases are for 9 years—some are for 12 years. They are written contracts drawn up by a notary. The farmer must manure his land according to local custom. In the last year of his lease, he is restricted as to the extent of cropping.

Baron von Gronow, Prussia.—Small parcels are let out from 1 year to 3 years; but farms, properly so called, with home-steads, are let upon a lease of 12 or 18 years. No one would take a farm with less than a twelve years' lease. The contracts are in writing. The farmer is precluded, *by law*, from selling straw or meadow hay; most contracts forbid him to sell such feeding stuff as clover, mangold, &c. The rotation of crops is very seldom mentioned.

Dr. Perels, Prussia.—As a rule the state domains are let on 12 year leases, short leases are the exception. Leases are always in writing, there are limiting conditions, particularly as regards selling straw; which, for instance, on the state domains is prohibited—furthermore, conditions are made that a restorative rotation of crops shall be observed, and that the land shall be kept in a fertile state.

Monsieur Lecouteux, France.—Leases are from 3, 6, and 9 years. The *métayer* is by the year. There are few written

and registered leases. The stipulation is by word of mouth or private unstamped agreements. No covenants are given for maintaining the fertility of the soil.

Monsieur Gustave Hamoir, France.—Leases are generally and almost entirely for 9 years. The leases are generally made out by deeds before a notary; each proprietor adds some particular clauses of little importance. The rotation of crops is no longer stipulated for, except indeed for the last 2 years. What is most generally required is a thorough manuring 3 years before the expiration of the lease.

Monsieur de Pimpin, France.—Land is let in the north of Touraine, on leases of 3, 6, and 9 years. The rent days being the 24th of June or the 1st of November of each year. In the south the leases are for half the crops. Leases are stamped and sealed, they contain many stipulations prohibiting the farmer from exhausting the soil, and which often oblige him to manure it; but these agreements are seldom or never observed. The landlord is tolerant, and the lease runs its course without any improvements taking place.

Monsieur Lapointe, France.—On leases of 9, 12, and 18 years. Leases are always in writing, and generally contain a prohibition against selling off green food or fodder, roots, &c.

Monsieur Bovet, Switzerland.—Generally on leases the term 3, 6, and 9 years, with a right of continuity if there should not have been a twelve-month's notice given. Leases are in writing throughout almost all Switzerland. In western Switzerland a stipulation is made, that no more than three white crops shall follow together, and no more than two of the same kind. Also, the extent of cereals, root-crops, and industrial crops that may be grown is sometimes specified—generally, a third of the total area.

Mr. Whitmore, Italy.—The length of contracts is 9 years; but sometimes, as short as three years. The general opinion is that it would be better if leases were of longer duration. Leases are in writing, some even are printed and explain all that the farmer has to observe, not only for the rotation of crops, but the manner in which the work is to be done; and also, as to the management of the beasts or cattle.

Dr. Fuchs, Galicia.—The lease of large and small plots of land is from 3 to 6 years. They are in writing and contain reciprocal conditions. The tenant is not allowed to sell straw from the same but must make it into manure. Rotation of crops is not specified; but for small plots of land no conditions whatever are named.

Dr. Fuchs, Austrian Silesia.—Leases are for 4 years. For large estates 25 year leases are frequently given, for medium sized farms 10 year leases are generally given. Leases from 1 to 4 years are only verbal, longer leases are in writing and the tenant is constrained to keep the land in good order.

Dr. Fuchs, Moravia.—On leases of 12 to 21 years. In writing. Exhaustion of land is prevented by the covenant that on every 4½ to 6 acres one head of grazing cattle must be kept, and the dung produced must only be used on the farm and cannot be sold.

Herr Fehér, Hungary.—Land is let on lease mostly for 6 years, some for 9 and 12 years; sometimes for longer periods. Contracts are in writing, the stipulations are exact with respect to the system of cultivation.

Have you game laws in force, and, if so, does the landlord reserve to himself the right of sporting?

Monsieur Leclerc, Belgium.—There is a very stringent game law in Belgium; the result is, so much game is often preserved, that farmers have frequently to complain of its ravages. The right of shooting is always reserved by the landowner, if not for his own pleasure, for letting to others. About 3s. per acre is paid for the right of sporting.

Baron Peers, Belgium.—Our game laws are severe; without a licence, which costs 26s., it is not permitted to shoot even on one's own estate. The proprietor reserves the right of shooting in the lease.

Herr Joest, Prussia.—We have no game laws; but the proprietors reserve to themselves the right of shooting.

Baron Gronow, Prussia.—Yes; but the law gives also some security against damage done by game, going so far as allowing the tenant to kill it, if the proprietor does not keep it in bounds. Nearly always the proprietor retains the right over the game.

Dr. Perels, Prussia.—Game laws exist; but from time to time there is agitation for their repeal or alteration. The

proprietor has not the right of shooting, except he has 180 acres of land.

Monsieur Lecouteux, France.—The law protects the game—too much so. The landlord reserves the right of shooting.

Monsieur Gustave Hamoir, France.—We have a game law; I herewith send you a copy. On account of the great subdivision of the land, the owner has little interest in reserving the right of shooting; he only does so when he possesses a large amount of land in his parish. As a rule, the right is given to the farmer, who is in a position to prohibit the entry to his field to anyone who might cause damage.

Monsieur de Pimpin, France.—We have laws which regulate the beginning and close of shooting, so as to prevent the total destruction of game. As a rule, the landlord reserves the right of shooting.

Monsieur Lapointe, France.—The game law of France is dated May 3, 1844. The landlord generally reserves the right of shooting by a clause in the lease.

Monsieur Bovet, Switzerland.—In nearly every canton there exists a game law. The shooting season begins September 1st, and ends December 31st. There are, however, some exceptions, as there are open times between the latter date and the end of February.

Mr. Whitmore, Italy.—In the sense understood in England, there is no game law here. There has lately been one passed prohibiting the destruction of birds during the hatching season, and no man can shoot on the land of another without leave.

Dr. Fuchs, Galicia.—There are laws for the preservation of game. When there is any quantity of game, it is generally let with the land.

Dr. Fuchs, Austrian Silesia.—There are laws; but they are not enforced. Tenants of large plots are bound to keep poachers off their land.

Dr. Fuchs, Moravia.—Unfortunately none. A farm of more than 300 acres entitles to the right of sporting; otherwise it is let in districts to the highest bidder.

Herr Fehér, Hungary.—We have game laws; and the right of sporting is reserved by the proprietor.

What are the crops usually grown, and in what rotation? and what is considered a good average yield?

Monsieur Leclerc, Belgium.—Cereals: Wheat, rye, barley, oats, buckwheat; Roots: Turnips, carrots, beetroot, and potatoes; Plants used in industry: Colza, rape, flax, sugar-beet, hemp, hops, chicory, tobacco; Vegetables: Vetches, beans, horse-beans; Fodder. The rotation of crops is triennial or quadrennial.

Wheat	22 bushels per acre.
Rye	23 " "
Barley	38½ " "
Oats	37½ " "
Colza	26 " "
Flax	...	(of grain)	10½ " "
Do.	...	(fibre)	14½ cwt.
Beetroot	17 tons "
Beans	28½ bushels "

Baron Peers, Belgium.—Our harvests in the sandy districts are: Wheat, rye, oats, potatoes, buck-wheat, haricot beans, white turnips. On fallows or upon very ordinary land, spergula is cultivated, cut green. The rotation of crops is as follows: Wheat (when the land is suitable), rye, oats (without clover), flax, potatoes, beetroot, or carrots. Upon manured oat land, clover; upon manured rye, an alternate crop of turnips. A full crop is considered:—

Of Wheat	26½ bushels per acre.
" Rye	27½ " "
" Oats	38½ " "
" Buckwheat	26½ " "
" Peas	23 " "
" Colza or Rape	22 " "
" Beetroot	16 tons "
" Potatoes	12½ cwt.
" White Potatoes*	36 " "
" Do.†...	28 " "
" Flax (in fibre)	4½ " "

* On fallow. † As an alternate crop after rye.

Herr Joest, Prussia.—Rape (highly manured), wheat, rye (slightly manured), clover, oats; or, wheat (manured), sugar-beets (without manure), rye, clover, oats.

Wheat	35 bushels per acre.
Rye	33 " "
Oats	46 " "
Rape	45 " "
Beetroot	about 12½ tons "

Baron Gronow, Prussia.—Rye, wheat, barley, oats, pulse, red clover, white clover, lucerne, Esparsette, cow-grass, Swedish clover (*trifolium hybridum*), rye-grass, Timothy grass, and other grasses, Indian corn (for feeding geese), rape-seed, flax, potatoes, mangolds, lupins. The rotation is very different, but nearly a four years' course:—

1. Potatoes or Mangolds.	3. Clover.
2. Barley or Oats.	4. Rye or Wheat.
Rye	27 bushels per acre.
Wheat	23½ " "
Barley	33½ " "
Oats	36 " "
Potatoes	7½ tons "
Mangolds	11½ " "

Dr. Perels, Prussia.—In my district, wheat, rye, oats, barley, peas, potatoes, roots for fodder, sugar-beet, clover, lucerne, are grown. A strictly-observed rotation of crops does not exist, but it is the usual practice to observe a change between green and white crops. A good yield may be considered:—

Wheat	45 to 60 bushels per acre.
Rye	35 45 " "
Barley	50 60 " "
Oats	50 120 " "
Peas	— 30 " "
Potatoes	— 8 tons "
Turnips	12½ 25 " "

Monsieur Lecouteux, France.—Cereals; fodder of all kinds; meadow-grass. Little wheat, which yields from 14½ to 18 bushels per acre, but, in carefully cultivated fields from 22 to 27 bushels per acre. Much rye, yielding from 18 to 24 bushels per acre. Fodder yields from 32 to 40 cwt. per acre.

Monsieur Gustave Hamoir, France.—

Beetroot	or	Beetroot
Wheat				Wheat
Clover				Oats
Wheat				Clover
Oats				Beetroot
Beetroot				

Large farmers have no rotation of crops. Many have one-third to one-fourth of their land in beetroot; the largest farmers, one half and more in roots.

Per acre.

Beetroot	18 tons.
Wheat	31 bushels grain
Oats	60 " "
Clover	1st cut, 2 tons
	2nd cut, 1 ton.

Monsieur de Pimpin, France.—Corn, rye, root-crops, oats, and artificial grasses. The *petite culture* follows a five-course shift in the south of the department: 1st year, corn; 2nd, clover; 3rd, pasture; 4th, fallow or root crops; and 5th year, small grain. In all the north there is no regular rotation of crops; but, mostly, cultivation is conducted on a three-course system: 1st year, rye or wheat; 2nd year, oats; 3rd year, fallow. High farming follows the three-course system: 1st year, root crops; 2nd year, corn; 3rd year, artificial grasses. The yield on small farms, where little manure is used, is of corn, say 10 to 12 bushels per acre. In good farms the yield is 30 to 36 bushels per acre of corn, and 12 to 16 tons per acre of beet-root.

Monsieur Lapointe, France.—Ordinary rotation: 1st year, fallow, clover, potatoes, beetroot, peas, lentils, vetches or beans; 2nd year, wheat; 3rd year, oats, barley, rye. Out of the rotation we cultivate lucerne and rape, also the vine. The mean yield is:—

Wheat	18 bushels per acre.
Oats	24 " "
Barley	22 " "
Rape	6 " "
Wine	168 gallons "
Potatoes	4 tons "
Beetroot	6 " "

Monsieur Bovet, Switzerland.—Very few fixed rotations. In Western Switzerland, wheat, oats, rye, barley, roots, rape or colza, a little tobacco, sainfoin, clover, lucerne, &c. *German Switzerland*: Coarse wheat, wheat, rye, oats, potatoes, clover, many fruit-trees. Wheat, 30 to 34 bushels per acre, maximum 43 bushels ditto; oats, 36 to 42 bushels per acre, maximum 54 bushels ditto. On the table-land of Western Switzerland in proportion to the seed, wheat 6 to 10 to 1, and oats 8 to 15 and even 20 to 1. Potatoes give 144 bushels per acre, carrots 240 ditto, beetroot 480 ditto. Natural meadows 16 cwt. to 1 ton per acre; considerably more in central Switzerland; artificial meadows 24 to 36 cwt. per acre; on the mountains 8 cwt. per acre; the most in the Jura.

Mr. Whitmore, Italy.—The principal products are: Hemp, wheat, Indian corn, and green crops. The rotations are, in lands good enough for growing hemp: Wheat after hemp; and on the lands not good enough for hemp: Indian corn, after wheat, and sometimes trefoil, wheat, and hemp.

Wheat	yields about	14 bushels per acre.
Indian corn	"	21½ "
Hemp	"	10½ cwt. "

Dr. Fuchs, Galicia.—Wheat, rye, barley, oats, rape, potatoes, and carrots. The potatoes and carrots are not grown upon the small farms. The usual rotation is: 1st, green crop, manured with 3 cwt. of artificial manure per acre; 2nd, rape; 3rd, wheat; 4th, clover; 5th, rye, with 1½ cwt. of artificial manure, or 3 cwt. of bone-meal; 6th, oats. Another rotation is: 1st, roots manured; 2nd, barley; 3rd, clover; 4th, wheat; 5th, rye, with 3 cwt. of human manure or bones; 6th, oats.

Dr. Fuchs, Austrian Silesia.—The crops grown are potatoes, mangold, barley, wheat, rye, clover, oats, flax, and a little rape. The rotation of crops on small farms which will not grow clover is: 1st, potatoes; 2nd, rye; 3rd, oats; 4th, pasture. When the land will bear clover the rotation is mostly: 1st, potatoes; 2nd, barley; 3rd, clover; 4th, wheat or rye; 5th, oats. The yield is as follows: Mangold 10 tons per acre, potatoes 5 ditto; wheat 20 bushels per acre, rye 20 ditto, barley 35 ditto; oats 30 to 40 ditto; clover-hay 30 cwt. to 2 tons per acre; meadow-hay 15 cwt. to 17 cwt. per acre. The irrigated meadows give a great deal of grass, but of bad quality; flax, 1 ton of fibre; rape, seldom more than 12 to 15 bushels per acre, on account of the cockchafer. Pease grown between rows of potatoes give 2 to 3 bushels per acre.

Dr. Fuchs, Moravia.—Wheat, rye, barley, oats, millet, maize, apeseed, potatoes, mangold, and sugar-beet, white and red clover, lucerne, "Espanzette," hops, caraway-seed, carrots, &c. Wheat 15 to 18 bushels per acre, rye 15 to 18 ditto, barley 30 ditto, oats 30 ditto, millet 18 ditto, maize 40 ditto, rape-seed 20 ditto; potatoes 4 tons per acre, mangolds 13½ ditto, sugar-beet 10 ditto, carrots 10 ditto; caraway-seed 12½ cwt., hops 4½ ditto.

Herr Fehér, Hungary.—Crops generally grown: Wheat, barley, rye, oats, Indian corn, rape, millet. 1st year, wheat, rye, or rape; 2nd, barley, oats, or Indian corn; 3rd, fallow or fodder (green). The average crop is:—

Wheat	12 to 18 bushels per acre.
Rye...	14 " 18 "
Barley	13 " 15 "
Oats	15 " 20 "
Indian corn...	12 " 20 "
Rape	8 " 20 "

Is guano, bone, or other artificial manure much used? If so, for what crops? and what quantity is applied?

Monsieur Leclerc, Belgium.—We use in Belgium guano, animal charcoal, superphosphate of lime, crushed bones, turf ashes, powdered oilcake, rape, and woollen refuse, lime, marl, fecal matter, and town mud.

Baron Peers, Flanders, Belgium.—Much guano is used, particularly on the light lands. It is the custom to use it at the rate of two cwts. per acre.

Herr Joest, Prussia.—Guano for rye, 3 cwts. per acre.

Baron Gronow, Prussia.—Bones, superphosphate of bones, or "Baker guano." Nitrate of soda, sulphate of potash, sulphate of magnesia, and gypsum are much in use. The use of guano has decreased. The bones and most of the other artificial manures are used for rye, wheat, potatoes, and

mangold, gypsum for clover, sainfoin, and lucerne; sulphate of potash on very light or moory land (1½ to 3 cwts. per acre.)

Dr. Perels, Prussia.—Artificial manures are much used, mostly for early crops, and indeed in quantities of 5 cwts. per acre; chiefly are used, Peruvian guano, superphosphates made from Baker Island guano and ground bone, ammoniacal superphosphates, dissolved bones, pure bone meal, Chilian saltpetre, and alkaline salts.

Monsieur Lecouteux, France.—Guano 1½ cwts. per acre, fossil phosphates 4 cwts. per acre, animal charcoal 10 bushels per acre, sulphate of ammonia 1½ cwts. per acre, superphosphate 1½ cwts. per acre.

Monsieur Hamoir, France.—Artificial manure is beginning to become popular. Some use guano at the rate of 3½ cwts. per acre, besides 16 tons per acre of farmyard manure. Others apply 9½ cwts. per acre of rape or colza cake, 1½ cwt. per acre of guano, besides the farmyard manure. Oilcake is the manure most used. Guano is becoming less esteemed, because it gives bad sugar beet-root. I have established a manufactory of artificial manure suitable for different plants and soils, which has increased considerably, and excites competition.

Monsieur de Pimpin, France.—In "petite culture" no artificial manures are used; but, on large estates farmed by their owners, from 2½ to 3 cwts. per acre of Peruvian guano is used.

Monsieur Lapointe, France.—The only artificial manure employed is gypsum, for clover, lucerne, and vetches, about 7 bushels an acre.

Monsieur Bovet, Switzerland.—Very little guano; a little pulverised bones, about 9 cwts. per acre generally. Several progressive farmers are now engaged in making comparative trials thereon, also the Alpine Societies for the mountain districts. In the Jura marl is used as manure.

Mr. Whitmore, Italy.—They are beginning now to use bones and other artificial manures, but for the hemp lands it has long been the practice to employ crushed linseed cake at the rate of about 12 cwts. per acre, costing about £4 16s. per acre.

Dr. Fuchs, Galicia.—Guano is rarely used with us; it is too dear. We mostly use human manure in powder, at 8½ cwts. per acre, or bone meal at 5½ cwts. per acre.

Dr. Fuchs, Austrian Silesia.—Guano is never used; lime and gypsum are used.

Dr. Fuchs, Moravia.—Crushed bones, wood ashes, and lime for straw and root crops.

Herr Fehér, Hungary.—Very seldom. It depends whether there is much stable manure or not.

What is the usual depth of cultivation for root crops, and what for cereals?

Monsieur Leclerc, Belgium.—Depth for cereals, 6 to 7 inches; roots, 8 to 9 inches. Deep ploughing is not generally practised. On the small farms the land is sometimes dug to a depth of 8 or 10 inches.

Baron Peers, Flanders.—The usual depth for cereals is from 4 to 5 inches; for roots, 8 to 10 inches.

Herr Joest, Prussia.—For beet-root 13 inches, and for cereals 10 inches.

Baron Elsner von Gronow, Silesia.—The land is cultivated from 9 to 12 inches deep.

Dr. Perels, Prussia.—The average depth of ploughing for cereals is 7 inches, and for turnips and potatoes 12 inches.

Monsieur Lecouteux, France.—6 inches is the general depth of cultivation of the country; 10 inches deep is attained in good cultivation.

Monsieur Gustave Hamoir, France.—In ploughing for roots 10 inches is the ordinary depth; the large farmers who have plenty of power turn up the soil 12 to 14 inches, and often 16 inches deep. The depth of ploughing for cereals is 7 to 8 inches.

Monsieur de Pimpin, France.—A great deal of land is ploughed only 2 to 4 inches deep. On well managed farms the depth of cultivation is 8 to 10 inches deep.

Monsieur Lapointe, France.—The depth of cultivation varies from 4½ to 6 inches.

Monsieur Bovet, Switzerland.—6 to 8 inches deep for cereals; for roots up to 12 inches deep. The introduction of new ploughs has increased the mean depth from 4 to 6 inches.

Mr. Whitmore, Italy.—The medium depth for cereals is

18 inches; for the hemp crop even deeper culture is resorted to. Roots are not grown.

Dr. Fuchs, Galicia.—The usual depth for white crops 6 to 7 inches, and for roots 8 to 9 inches. A subsoil plough is seldom used.

Dr. Fuchs, Austrian Silesia.—On large estates the depth is 7 inches in the spring and 9 inches in the autumn.

Dr. Fuchs, Moravia.—For roots, 16 inches deep; for corn, 6 inches deep.

Herr Fehér, Hungary.—For roots 7 to 10 inches, and for cereals 4 to 6 inches deep.

What wages are paid to the farm labourers in the winter months, and what in the summer? Say how much in money and how much in rations. What extra wages (if any) are paid during the harvest months, either in money or in rations?

Monsieur Leclerc, Belgium.—The average wages of farm labourers are 1s. 1d. per day without food, and 7½d. with food. The maximum wage without food is 1s. 6d. for men and 11d. for women; the minimum is 9d. for men and 6d. for women. With food the maximum wage is 11d. for men and 6d. for women; the minimum is 5d. for men and 3d. for women. Workpeople engaged by the year do not receive anything extra at harvest-time, but day labourers are paid 2s. 6d. to 3s. 2d. per day at this season. In many parts the harvest is gathered by men working by the piece, who earn from 4s. to 4s. 9d. per day. In the cultivation of the soil of Belgium it is computed that the labour amounts to 27,600,000 men's working days, and 14,660,000 women's working days.

Herr Joest, Prussia.—Wages are 1s. 2d. to 1s. 6d. per day in summer, and 1s. to 1s. 3d. in winter—all paid in money. 3½d. to 6d. per day extra is paid in harvest. Many women are employed who receive about 1s. per day. No farm-work is done by the piece.

Baron Elaner von Gronow, Prussia.—Wages are 4d. a day in winter, 5d. in spring and autumn, 7½d. to 10d. in harvest, without victuals. In harvest a little corn brandy is given. Unmarried women and widows are extensively employed; their wages are about 1d. less than the labourer. In harvest-time they are paid 5d. to 6d. per day. As much work as possible is done by the piece.

Dr. Perels, Prussia.—Women earn from £7 4s. to £9 a year; they are boarded like the men. Industrial farming has a good deal of work done by the piece. The average wages of field labourers are 1s. 6d. a day in summer, and 1s. per day in winter; as a rule they are paid in cash, not in rations. The rise of wages in harvest-time varies; it depends upon competition; in pressing times it is often double. We employ many women in field-work, who receive as a rule one-third less than men. Piece-work is becoming more and more general; all kinds of work are done by the piece.

Monsieur Lecouteur, France.—Wages are 1s. 7d. per day in summer, and 1s. 3d. per day in winter, without provisions; but much work is performed by the piece at this season and at other times. Few women are employed; their wages are 10d. in summer and 7d. in winter.

Monsieur Gustave Hamoir, France.—One or two men are hired by the year, and are paid a fixed wage of 24 to 27 bushels of corn for the summer months, and 2s. a week in money for the rest of the year, besides 8s. at the hiring and at festivals. In harvest-time piece-work is the rule, and a man may at this season earn from 3s. to 4s. a day, and a woman 1s. 8d. The general wages of women are 10d. per day in summer, and like the men they often work by the piece. I send you the tariff for the various operations performed upon the farm:—

Cutting hay, clover, lucerne, &c.; first cut...	3s. 6d. per acre.
Ditto ditto second cut	2 11 "
Bag hooking corn, oats, &c....	5 5 "
Putting in sheaves not bound	1 4 "
Ditto in shocks	2 3 "
Making binds	0 8 per 100
Cocking clover, lucerne, &c.	1 4 per acre.
Hand-sowing cereals	0 5½ "
Ditto artificial manure	0 7 "
Spreading dung, (16 tons per acre)	1 4 "
Ditto lime	1 4 "
Loading and unloading manure	0 2½ per ton.
Emptying the stables of manure	0 4½ "

Hand-hoeing beetroot four times ... 12s. 9d. per acre.

(The horse-hoeing is supplementary)

Hoeing "rutabagas" once (artichokes) ... 3 2 "

Drawing beetroot, cutting off leaves, and loading up ... 13 10 "

Setting out Jerusalem artichokes ... 10 10 "

Feeders of the thrashing machine, per hectolitre ... 0 0½ per sack.

Covering a stack ... 4 0 "

Monsieur de Pimpin, France.—A farm labourer engaged by the year, and living in the house, has £12 to £14 a year—his board comes to about as much—he costs, therefore, from £24 to £28 a year. Farm labourers living in the house are paid by the year, and do not receive anything extra in harvest-time.

Monsieur Lapointe, France.—The farm labourers are boarded and lodged, and receive from 16s. to 24s. a month all the year round. Thirty days' work at harvest times are paid with 4 cwt. of wheat.

Monsieur Bovet, Switzerland.—A great difference exists. With board and lodging 8s. to 16s. a month, without board and lodging 1s. 8d. to 2s. 6d. a day in summer, 10d. to 1s. 8d. in winter. In remote districts still less. Sometimes drink, particularly wine, in the vineyard districts.

Mr. Whitmore, Italy.—As the system of "métagage" prevail, little work is done by the day. When it is, the wages are from 8d. to 10d. per day in winter and spring, and 1s. 2d. in summer. For extra work, such as cutting wheat, grass, and thrashing, the wages are 1s. 6d. to 1s. 10d. The women belonging to the families on the "métagage" farms work in some way or other. Hired women are paid about one-fourth less than the wages paid to men.

Dr. Fuchs, Galicia.—Farm labourers receive in summer 9d. per day, and in winter 6d. They have no provisions. In harvest they only receive money, from 1s. to 1s. 2d. per day.

Dr. Fuchs, Austrian Silesia.—The usual rate of wages for women and children is 5d. a day for hoeing potatoes in summer and digging; a little corn brandy is given. The men are employed by the year, and have board and lodging and £4 a year. Women employed by the year get £3 with board and lodging.

Dr. Fuchs, Moravia.—In summer 8d. to 1s. 4d., in winter 6d. to 10d. per day; only in money. When cutting corn, four points of beer per acre.

Herr Fehér, Hungary.—Wages vary much, and little money is parted with by the employer. The labourers are paid in provisions, or by a per-centage share, generally about £2 16s. per year in money, 60 bushels of corn, food for a cow, and a pig, and fuel and lodging free. No extras in harvest. Women are much employed, and get from 7d. to 1s. 2d. per day. The plan of piece work is increasing.

Have you an abundance of labour or a short supply? Have wages increased during the last 25 years? If so, to what extent?

Monsieur Leclerc, Belgium.—Manual labour is becoming more and more rare in Belgium, on account of the great development of industry and the high wages obtained by workmen who leave the country for the seats of manufacture. The insufficiency of manual labour is partly supplied by the use of machines, which have much increased during the last 10 years, particularly thrashing machines. Reapers and mowers are not yet much used. Wages have increased 2d. to 3d. per day since 1846.

Baron Peers, Belgium.—Although the population increases the farm hands decrease. Several causes tend to this. Wealth increases, and everyone seeks to better himself. Farm labourers earn little, work hard, and are exposed to all weathers; they are, however, much attached to the soil. Our nearness to France causes us to lose many. Emigration, however, is not much felt. Manufactories and mechanical pursuits abstract many of our people; and, as labour is more in demand, owing to a higher state of cultivation being carried on, the abstraction of labour is the more felt. Wages have increased during the last 25 years 30 per cent.

Herr Joest, Prussia.—Labour has become rarer and dearer, and wages have increased during 25 years from 25 to 35 per cent.

Baron Gronow, Prussia.—Being situated in the neighbourhood of a large mining district, labour is becoming a little rarer; therefore wages are rising. Twenty years ago we did not pay more than 2½d. a day in the winter-time, and now

wages are 4d. per day. 9d. an acre was formerly the price for mowing and binding an acre of wheat; now it is 2s. 3d.

Dr. Perels, Prussia.—In many districts the want of agricultural labour is much felt. The cause is that the many industrial and manufacturing establishments attract labour from the rural districts. Wages have risen in the last 25 years about 50 per cent.

Monsieur Lecouteux, France.—Hand labour is becoming scarce, and wages have doubled.

Monsieur Gustave Hamoir, France.—We have sufficient manual labour. Our district is covered with sugar factories. The price of manual labour is high for a short time during winter, whilst it is low in other places. This allows workmen to tide over difficult times without suffering, and to wait for the spring season. Emigration is insignificant in this part. Wages have risen 20 per cent. during the last 20 years.

Monsieur de Pimpin, France.—Labour is becoming scarce. When the wages are not what workmen can get in commerce or industry there is a rush to the towns; but when the same price is given for agricultural as for industrial work the rush to the towns will be stopped. This can be accomplished only by good agriculture, and above all by the adoption of piece-work. We pay 50 per cent. more wages than we did 25 years ago.

Monsieur Lapointe, France.—Labour is becoming scarcer and dearer, and the efflux of the country population is daily augmenting. The wages of farm labourers have trebled during the last 20 years.

Monsieur Bovet, Switzerland.—Scarce in the manufacturing districts, abundant elsewhere. When manufacturing business was good, 10 or 15 years ago, the agricultural population migrated to the towns, but now it returns to the fields. Berne, Valais, the smaller cantons, have the greatest population and greatest pauperism, particularly the two first-named cantons. An increase of at least one-third in wages.

Mr. Whitmore, Italy.—In this district (Bologna) there is plenty of labour to be had, but it is not so in other districts. Within the last 10 years day-labour has increased in cost more than double.

Dr. Fuchs, Galicia.—There is plenty of labour with us since forced labour ceased some twenty years ago. Wages have somewhat increased.

Dr. Fuchs, Austrian Silesia.—During the last few years, owing to the construction of railways, there has been a lack of labour. We can obtain labour, however, from the mountain districts, and are also beginning to use more machines. Since the year 1848, when serfdom was abolished, wages have increased 50 per cent.

Dr. Fuchs, Moravia.—In consequence of the building of railways and the sugar manufactories, and the rage for building in large towns, labour is become scarce. Very considerably; about $\frac{1}{4}$ times at least.

Herr Fehér, Hungary.—The want of manual labour is painfully felt. Since the free development of Hungary wages have enormously increased, i.e., during the last three years. In many parts the increase is 150 per cent.

Are cottages found for the labourers, if not, what rent do they pay? Does each married labourer occupy a separate cottage, or is one house occupied by a number of families? Has each married labourer a small plot of land allotted to him; if so, is it free, or subject to a rent?

Monsieur Leclerc, Belgium.—Hired farm servants are lodged at the homestead. Day labourers are lodged at their own expense in small houses which belong to or are let to them. A labourer's house in the country costs from £6 to £8 a year according to its size. In the poorer parts of the country a similar house lets for only £3 8s. a year. The general usage in Belgium is that each family has its own separate habitation even in towns. In the country one never finds several families in the same house. Every family in rural districts has a kitchen garden, and very frequently a small field, which furnish potatoes and grain for the family consumption. These gardens and fields are rented.

Baron Peers, Belgium.—Married farm labourers pay rent for their dwellings. Each has as a rule $\frac{1}{4}$ acres of land, for which he pays £4 a year. They have also to pay the usual imperial and parish taxes, which amount to from 1s. 8d. to 2s. 3d. Each labourer occupies a separate house, and but few

live together. He generally has a little kitchen, one or two bedrooms, a small cellar, a pump, a little stable for his cow or goats, also a little granary for his crops.

Herr Joest, Prussia.—Cottages are not found. Rent varies according to the locality. A labourer, as a rule, has a separate cottage; and each has a small plot of land, for which he pays a small rent.

Baron Gronow, Prussia.—Dwellings are found for the labourers, but they pay for the use of them a day's pay weekly. The houses consist mostly of two rooms, and a stall for a cow. Generally two or more families occupy one house. The practice, however, varies. The careful proprietors let some $\frac{1}{4}$ to $\frac{1}{2}$ acres of land to the labourer, or a garden about the house, on which to raise potatoes and to keep a cow or some goats. The labourers on the larger estates are nearly always allowed to collect the dry wood in the forest on fixed one day.

Dr. Perels, Prussia.—Farm labourers on large estates often have dwelling-houses found them, for which of course they pay rent. In most cases several families dwell in one house. As a rule the fixed labourer who is hired for several years has a plot of land allotted to him, which is cultivated by the landowner, and for which no rent is expected.

M. Lecouteux, France.—The labourers are lodged on my farm. They pay a rent of £4 per year. They have a garden, a cow, and a pig. Each labourer has his own room. One house contains several dwellers—four is the average.

M. Gustave Hamoir, France.—The farmer has nothing to do with finding the labourer a dwelling. A labourer has mostly a cottage belonging to him, either bequeathed by his parents or built with his first savings. The poorest have to hire their house from some house proprietor. Each family occupies a separate house. The farmer has nothing to do with the wants of the labourer; in exceptional cases, however, he lets him a small portion of land to cultivate, for which a rent is charged.

Monsieur de Pimpin, France.—In general, labourers are charged rent for their dwellings. About £2 a-year is paid to the landlord, a garden being included. Each family is lodged separately.

Monsieur Lapointe, France.—The farm labourers are generally house owners, having a garden attached to their house. They are often owners also of a small plot of land. Each family occupies a separate house. Sometimes the labourer has besides a right to a portion of the land belonging to the parish.

M. Bovet, Switzerland.—It is rare for them to be housed gratis. They pay £4 a-year for house and garden. In Western Switzerland the farm labourers live in the villages. In Western and Central Switzerland they have generally their own house, the population in those parts not being grouped in serried villages, as in the West. Nothing fixed; generally not; in any case not gratis.

Dr. Fuchs, Galicia.—The field labourers do not get a house. They are mostly small peasant farmers who possess a house, or pay 10s. to 16s. a-year for one. They have no land given them by their employer, but frequently possess a piece of their own.

Dr. Fuchs, Austrian Silesia.—On large estates farm labourers have houses provided for them, 16s. to 24s. being deducted from their wages in lieu of rent. They mostly have separate houses. When two or three families dwell under one roof they live separately. They have generally a small piece of land free of tithe and tax, for which they pay 16s. to 24s. a-year.

Dr. Fuchs, Moravia: Cottages are not found. Custom varies as regards married labourers; in most cases they rent houses.

Herr Fehér, Hungary.—A number of families often live in one house. Sometimes the labourer has a separate dwelling. In most cases each married labourer has three acres of land allotted to him free.

Have the cattle in your district suffered from foot-and-mouth disease or pleuro-pneumonia, and have your sheep been attacked with foot-rot or small-pox; if so, have you found any treatment medical or otherwise, efficacious?

Monsieur Leclerc, Belgium.—Pleuro-pneumonia has made serious ravages in Belgium on several occasions, particularly on the farms of beet-root distillers, who fatten much cattle. No good curative is known. Dr. Willems de Haselt has proposed inoculation as a preventive, and this method is prac-

tised by a large number of distillers and farmers, who maintain that it gives good results. The special commission, however, instituted by the government to experiment upon this system, has not been able to conclude anything positive from the numerous experiments which it has carried on for several years past. The foot and mouth disease is prevalent at this moment in almost all parts of Belgium. The animals suffer from a fortnight to three weeks, but few die. Cleanliness and the use of oximel (a mixture of water, vinegar, and honey) are the means employed for combating the disease. Small-pox and foot-rot are not frequent amongst our sheep.

Herr Joest, Prussia.—Our cattle have suffered, but no treatment has been found efficacious except repose and cleanliness.

Baron von Gronow, Prussia.—My cattle have been free from murrain, foot and mouth disease, or affection of the lungs; but in my neighbourhood nearly every herd of cattle suffered from foot and mouth disease. Affection of the lungs is common, because cattle are nourished on many farms with the refuse wash of the potato distilleries, which are very extensively combined with the larger farms. The sheep are well all over the country. Animals never die of the mouth and foot disease, but lose much flesh and milk. Wood vinegar,* and sulphate of copper are used as medicaments with success.

Dr. Perels, Prussia.—Cattle suffer from many diseases, foot and mouth disease at this moment is general. Pleuro-pneumonia is often prevalent. Sheep suffer from inflammation of the spleen, also small-pox and scab. In each district there is a veterinary surgeon appointed by the state (Kreis-thierarzt), there are also many private veterinary surgeons.

Monsieur Gustave Hamoir, France.—Foot and mouth disease and pleuro-pneumonia are two diseases which are frequently prevalent amongst us. The former presents itself as an epidemic, contagious to the last degree. It extends from neighbour to neighbour, and attacks all the stalls without sparing one. Pleuro-pneumonia is permanent in certain farms, but it presents itself rarely in its contagious character. In my opinion this malady arises, according to the hygiene or sanitary arrangements of the farm. If the animals being fattened are fed to an extreme degree, if the quantity of food absorbed exceeds the assimilative power of the organs, pleuro-pneumonia arises, and arises all the quicker if the substances given to the animals contain irritating and volatile matter, such as alcohol, acetic acid, or active essential oils. If the animals do not receive the quantity of food sufficient for their existence, or the quality which suits them—for instance, a cow poorly fed and having remarkable lactiferous qualities, draft oxen which are over-worked—in these cases pleuro-pneumonia will arise. In the first case the affection is easy to combat, because it suffices to modify the conditions of feeding, to weaken the animal, and diminish the inflammation of the blood, a result which is obtained with ease; but in the second case, when you have to feed up the animal in order to restore the equilibrium of its functions, a long time is necessary, during which the disease progresses and carries off the subject; therefore, pleuro-pneumonia created in these last conditions is much more terrible than the other. It is my opinion that a good farmer ought never to have this disease except in extreme cases of want of foresight, the causes of which depend upon himself, or upon circumstances over which he has no control. Sheep are rarely attacked with small-pox or other disease except foot-rot, which prevails almost continually. To cure it we cauterize the feet, having previously washed them with sulphate of copper.

Monsieur de Pimpin, France.—We have never had pleuro-pneumonia, but we have had foot and mouth disease in the cattle. The treatment we have followed consists in cooling food, cleanliness of the stalls, washing the feet of the bullocks and cows with fresh water, cleansing them with clean rags, and rubbing the affected parts with ointment.

Monsieur Lapointe, France.—At this time the cattle are suffering everywhere from foot and mouth disease, against which no remedy is used. Pleuro-pneumonia is not known in this district.

Monsieur Bovet, Switzerland.—Cattle has suffered excessively in one or two localities where the sick beasts have been slaughtered immediately by order of the government. In eastern Switzerland there have been some cases of typhus

imported from Austria, which has been stamped out in the same way. In western Switzerland there have been some cases of foot and mouth disease in cattle, and foot-rot in sheep; it has never been dangerous, but seriously hinders the sale of beasts while it rages.

Dr. Fuchs, Galicia.—Not only my cattle, but that of the whole neighbourhood have suffered from the mouth disease. Pigs had small-pox and diseased feet. Sheep are very little bred in my district, they had foot-rot. It was the first time my cattle had foot and mouth disease. Rinsing with acids, but principally with cold water, had a good result. I had my beasts driven four times a day into the water, in eight days the disease began to disappear, and in four weeks the beasts were quite well.

Dr. Fuchs, Austrian Silesia.—We have suffered from foot and mouth disease this year. We have had pleuro-pneumonia twice; the first time I believe from want of nourishment, the second time from giving them too much. Sheep are inoculated for smallpox, and thus preserved from it. All we have to fear here with the sheep is liver worms.

Dr. Fuchs, Moravia.—Cattle: Foot and mouth disease.—Remedy: (a) an embrocation of vinegar and salt; (b) petroleum. Lung disease.—Remedy: To inoculate and isolate in a wood, with good result. Inflammation of the Spleen.—Remedy: Puncture. Sheep: Inoculation against small-pox, quite efficacious.

What burdens are there upon the land in your country in the shape of rates or taxes for the support of the poor? How much do they amount to per acre? If no tax is levied per acre, is the income of the proprietor, or are the profits of the tenant taxed for this object? If no taxes are levied for the support of the poor, how are the destitute poor supported?

Monsieur J. Leclerc, Belgium.—Landed property in Belgium pays rates to the Government, the Province, and the Parish. These rates are based upon the assessed income fixed by the assessor. The assessed income is generally 25 per cent. less than the real income. The contributions to the Government vary somewhat, according to the different districts of the country under consideration. It is on an average calculated at the rate of 0.067 of the assessed income. The contributions to the Province are on an average 0.15 of those paid to the Government. The contributions to the Parish are very variable, according to the districts. They vary from 5 to 50 per cent. of the contributions to the Government. There are no special taxes on the land for the support of the poor. The summary of the taxes noted above may be estimated on an average at 5s. 6d. per acre. These taxes are based on the income of the proprietor derived from his possessions. The farmer has also to pay personal taxes towards the Government, Province, and Parish expenditure. The poor are relieved by the *bureaux de bienfaisance*, or public relieving offices, in the rural parishes. In towns there are, besides the *bureaux de bienfaisance*, hospital-boards (*administrations des hospices*). These two institutions, which are under the control of the Government, have for the most part—the hospital-boards (*administrations des hospices*) always—properties of more or less importance, resulting from donations, legacies, &c. The *bureaux de bienfaisance* are subsidized by the parishes when they have no longer sufficient resources. Several hospital-boards, those for example at Brussels, Nivelles, and Namur are very rich, and cannot find ways to employ all their revenues.

Baron Peers, Flanders, Belgium.—All the land in Belgium is surveyed and assessed at 5s. 6d. per cent. Thus there are four or five classes of land, and it is upon the assessment that the impost is raised; for instance, a hectare (2½ acres) of land is rated in the register as worth £4. The State levies 5s. 6d. annually thereon, and upon this levy of 5s. 6d. are superadded "additional centimes," with which the State, the Province, and the Commune meet their expenses. The destitute poor are supported by the (*bureaux de bienfaisance*) public relieving offices, of the parishes and townships of the kingdom, all of which possess real property for the succour of the poor. Only workhouses are paid by the parochial Boards, which disburse for the poor contained therein, their daily expenses varying from 5d. to 6d.

Herr Joest, Rhenish-Prussia.—There are no burdens upon the land for the support of the poor; but each parish has to see to its own poor.

* I do not know the English expression for "Holzessig," perhaps methylated vinegar. It is vinegar out of the distillation of wood.

Baron Gronow, Silesia, Prussia.—The poor-rates are not paid by the landowners alone, but by every sort of tax-paying people: they are on land-tax, building-tax, income-tax, and the trade-taxes.

Monsieur Lecouteux, France.—All the taxes together upon land amount only to from 4d. to 6d. per acre. The taxes are levied upon the proprietor and not upon the farmer. The support of the poor rests with the *bureaux de bienfaisances* and private charity.

Monsieur Bovet, Switzerland.—In some cantons there are no burdens, land paying a direct tax like any other capital. At Neuchâtel the landlord pays for his land as his capital, and the farmer pays on his profits. In other cantons each pays on his revenue. The poor are generally dependent upon the parish and private charity.

Mr. Whitmore, Italy.—There is no special tax for the poor; the destitute are supported by charitable societies dependent upon voluntary contributions and legacies.

Herr Fehér, Hungary.—There are no poor-rates. The destitute are supported from the treasury of the parochial Board, to which all are bound to contribute.

What rates or taxes does the land have to bear for the maintenance of roads, bridges, &c., or are they maintained by tolls levied upon the passing traffic?

Baron Peers, Flanders, Belgium.—Formerly there were turnpikes to meet the expenses of repair and maintenance; now it is with the aid of State "additional centimes" that the roads are maintained. Formerly there was a system of voluntary labour of men and horses; all this has been abolished, and the new system answers.

Herr Joest, Rhenish-Prussia.—Maintained by tolls.

Baron Gronow, Silesia, Prussia.—The macadamized highways, as well as some of the bridges are kept in order out of the tolls. The common roadways are kept in order by the landowners of those communities through which they pass.

Monsieur Lecouteux, France.—The roads are maintained by the State, the Département, or the Commune; there are no tolls. The high-roads are maintained by the State. The bye-roads by extra centimes added to the fixed taxes levied by the Communes.

Mr. Whitmore, Italy.—There are taxes called "communal" and "provincial," also "tassi suol dell terra." These taxes are imposed upon the landowners or occupiers for the expenses of maintaining roads, bridges, canals, &c., and for regulating which there are commissioners expressly appointed. There are no toll-gates.

Herr Fehér, Hungary.—The Government maintains the high-roads; the provincial roads are maintained by the province. Turnpikes are abolished.

Is any portion of the expense for the punishment of crime and support of prisoners levied by any tax on the land or income of the farmer?

Monsieur Leclerc, Belgium.—All borne by the State.

Baron Peers, Flanders, Belgium.—No impost is levied to maintain criminals. The budget for carrying out justice (voted every year by the Chambers) takes into account these expenses. The expenses only for mendicity are at the charge of the parish.

Baron Gronow, Silesia, Prussia.—There is no tax on the land or income of the farmer. The State pays out of its revenues for the maintenance of criminal prisoners.

Monsieur Lecouteux, France.—The expenses of the punishment of crime and the support of prisoners are borne by the State.

Monsieur Bovet, Switzerland.—Both expenses paid by the State.

Mr. Whitmore, Italy.—These are all Government expenses.

Are there any compulsory payments either in tithes or rates for the support of the Church? If so, what is the amount per acre or upon income, on the case may be?

Monsieur Leclerc, Belgium.—There are no special compulsory payments, although the ministers of religion are supported by the State. The expenses of worship are defrayed by the revenues of the Societies for the Building of Churches, which are generally possessed of property; and in case of insufficiency the Government intervenes with a subsidy.

Baron Peers, Flanders, Belgium.—There are neither tithes nor compulsory payments for the maintenance of worship. The expenses are defrayed by the State out of its revenues, and are estimated for in the budget.

Baron Gronow, Silesia, Prussia.—The landowners are compelled to pay for church building. The other payments from landed property to the Church are converted into a rent payable to the State. That rent has a sinking fund, and the capital is made over to the Church. The rent varies much in different localities.

Monsieur Lecouteux, France.—There are no tithes or rates levied on land for the support of the Church.

Monsieur Bovet, Switzerland.—There are no rates or tithes for the support of the Church in the Protestant Cantons. I have no knowledge of what is done in the Catholic parts.

Mr. Whitmore, Italy.—The lands are subject to a payment called "decima," or tenth-parts, which in reality is about 12 per cent., 8 per cent. of which goes to the bishop and 4 per cent. to the priests. But a law has lately been passed for freeing the land of this tax or tithe, and allowing the proprietors to buy it up at so many years' purchase.

Are there any other imports or taxes levied upon the land, either for imperial or local purposes? If so, for what purposes, and what do they amount to per acre?

Baron Peers.—The parish tax is raised, as already stated by the several parishes, to meet all needs, and is levied according to its presumed wealth.

Baron Gronow.—In Silesia and some other parts of Prussia a land-tax existed for more than a century. In 1860 the land-tax was regulated all over the kingdom. It is paid to the treasury for no express use. As the land-tax is paid after a fixed estimate of the revenue, it is very diverse—bad land paying a small one and good land a high one.

Monsieur Bovet.—Imports are levied in some cantons for the destruction of cockchafers, lice, and mice, also for the keeping of a bull for breeding purposes, &c.

Mr. Whitmore.—Besides the taxes already given, there are Government taxes which amount to about 15 per cent., based upon the amount of the last valuation, which, however, is only equal to about one-third of its real value.

In your school system, is the land or the income of the farmer taxed for the support of the schools? Have you a law to compel the attendance of children at school until they arrive at a given age? If so, what is that age? If not, do the majority of parents send their children voluntarily? Have you a law to prevent children being employed until they arrive at a given age? If so, at what age do children begin to work upon the farm?

Mons. J. Leclerc, Belgium.—By our system of parish schools for the education of children of the working-classes, poor children are received therein gratuitously. The funds necessary for these schools are taken out of the ordinary resources. They are furnished in part by the parishes, and in part by the State. The State intervenes with subsidies, which amount generally to a third of the expense in the construction and furnishing of the school buildings. The province also grants subsidies for this object, but they are less important than those furnished by the State. There are at this time in Belgium 3,511 parish schools, 627 private schools subject to inspection, 1,492 private schools perfectly free; in all, 5,630 elementary schools. The first are attended by 882,484 pupils, the second by 73,824, and the third by 107,408—total, 563,718, for a population of 4,827,883 in our kingdom.—Compulsory education does not exist in Belgium. It has been a question during the last three years, and an interesting discussion on this subject took place recently in the Chamber of Representatives, but without result. This system has numerous partisans here, but it is generally believed that its application presents great practical difficulties. The principle is that Belgium, in spite of the considerable sacrifices that the Government has made during several years for the sake of elementary education, is not yet sufficiently provided with schools and school-masters to allow of compulsory education being efficaciously applied. The law allows benevolent societies to withdraw their succour from poor parents who do not send their children to school. This is the only measure of coercion which we have. The majority of parents send voluntarily their children to the parish schools. Statistics show that amongst the young men of 19 years of

age, who draw lots for the militia, there is only 24 per cent. who can neither read nor write; but this is not a precise basis, because many young men who attended the elementary schools have forgotten what they learnt when they come to the age for drawing for the militia. According to the statistics of the elementary instruction which I have given in a previous answer, the relation between the number of pupils and the total population of the kingdom is 11.7 per cent., but the number of pupils indicated does not comprise the children of the age of 7 to 14, which are admitted in large numbers to the ordinary schools and reformatories. Children begin to work upon the farm generally at the age of 14 or 15 years, when regular work which requires a certain physical force is required. In certain parts of the country children from 11 to 12 years of age are employed to drive cows, sheep, and pigs to the pasture lands, and watch them there. In this case these children attend school in the winter.

Baron Peers, Flanders, Belgium.—We have no compulsory school regulation for enforcing attendance, but instruction is free under laws issued by the State. The majority of parents send their children to school voluntarily.

Baron von Gronow, Silesia, Prussia.—School buildings are maintained by the landowners. The maintenance of the school-master is arranged in different ways. If he receive part of his salary in kind, say, in corn or fodder for cow, the landowners are bound to give it. This payment in money is distributed amongst the landowners and the houses. Sometimes a very small "school money" for every child is asked, not exceeding 1s. 6d. yearly for the child. In harvest-time there is all over Silesia a vacation of four weeks, and in the potato harvest a fortnight, during which the children are employed. If the children are not sent to school, a penalty upon the parents is enforced. As one part of the children goes to school in the morning and the other part in the afternoon, no inconvenience is felt.

Monsieur Lecouteux, France.—The cost of our schools is borne by the State and the Commune. Each scholar pays a fixed fee of 10d. per month for boys, and 1s. for girls. Education is not compulsory, but schools are more and more frequented. Children commence work upon the farm about 12 years of age.

Monsieur Bovet, Switzerland.—Education is gratuitous and compulsory for every class, and is paid for by the commune and the State. In the Canton of Neuchâtel children are compelled to attend school until the age of 14 years. There are evening schools for the period of 14 to 18 years.

Mr. Whitmore, Italy.—There are rural schools, free to the children of both sexes, provided by the taxes. At present there is no law of compulsory attendance, but the question has been noticed in the Chambers, and a law is expected compelling attendance until 14 years of age. The children are sent to school in the winter; at other seasons the schools are deserted.

Is the "métayer" system adopted in any part of your country? If so, with what result?

Baron Gronow, Silesia, Prussia.—Only where tobacco planting is common. Here there is a kind of "métayer" farming.

Monsieur Lecouteux, France.—The "métayer" system predominates in many districts because the farmers have not sufficient capital of their own.

Monsieur Bovet, Switzerland.—It is rare in Switzerland. The result depends upon the character of the contracting parties.

Mr. Whitmore, Italy.—The "métayer" system, or "mezzadria," as it has been called, is adopted by nearly all, the result being that nearly every kind of progress in agriculture is arrested. Under existing conditions, however, there is perhaps no better system for keeping the land from going back.

Is the transfer of land from seller to buyer simple and easy? or is it, as in England, hampered with legal expenses, delay, and difficulty?

Baron Peers, Flanders, Belgium.—The acquisition of land, although many guarantees are required, takes place easily. It is effected either by means of a public notary or from hand to hand. A registration fee, which amounts to 5 per cent, and a fee for inscription at the office of hypothec, which amounts to about 1 per cent. The notary prepares a minute of the stipulation of the sale, and delivers to the buyer an act of

transfer in due form. These are all the formalities in the case of minors, interdicts, or absentees. Then the tribunals are called upon to grant authorization by the entry into the assessment book of each parish. It is so easy to prove the property of each individual, as a plan is engraved by each parish, and divided into different sections. Each piece of land has its number. This has cost a good deal, but it is an admirable work. One can never be ejected. The revision of the assessor's book is made every two years by a surveyor paid by the Government. Every change of boundary alterations caused by purchase, are entered in registers for the time, as far as it goes, and rectified upon the plan of land plots of the parish. Thus, I have all the extracts of my property. At each change I betake myself to the central office, and the revision is made there and then. Three deposits of these maps are made. There is one in each parish, a second in the chief town of the province, and another at Brussels.

Herr Joest, Prussia.—The transfer of land is both simple and easy, but it is transferred in legal fashion. The stamp duty costs 1 per cent. upon the value. There are no hindrances or difficulties.

Baron Gronow, Silesia, Prussia.—The transfer of land is not so difficult as in England, but not so easy as we should like. We are urging a reform; nevertheless, an Englishman would think our system easy, simple, and cheap.

Monsieur Lecouteux, France.—The transfer of property is effected very readily.

Monsieur Bovet, Switzerland.—The transfer of land is very simple and easy.

Mr. Whitmore, Italy.—The transfer of estates is very difficult, as many formalities are necessary, besides a very heavy tax to the Government, amounting to 2, 4, and sometimes 5 per cent.

Herr Fehér, Hungary.—The sale and transfer of real property is saddled by no hindrance, but Imperial dues of from 1 to 8 per cent. are levied, according to whether the transfer is a gift, a sale or an inheritance.

Is any portion of the land in your country artificially irrigated? If so, with what result? and is the practice extending either by the application of town sewage or water?

Monsieur J. Leclerc, Belgium.—In some provinces, particularly in Luxembourg where the land is hilly and small water-courses abound, the water is used in the winter for artificial irrigation, but the results are not very satisfactory, because irrigation is generally badly conducted. The proprietors will not go to the necessary expense for levelling the land so as to facilitate the regular distribution and flowing off of the water. It is only in that part of the provinces of Antwerp and Limbourg, known under the name of "Campine" that well-established irrigation is found. With the view of fertilising this region, which 25 years ago was quite uncultivated, Government caused to be constructed about 120 miles of canals, which are fed by the River Meuse, and which serve simultaneously for navigation and irrigation. Since the year 1848 we have been able to create, by means of these canals, irrigated meadows, which occupy now a superficies of about 9,260 acres. The insufficiency of water has not permitted us to extend them more. The soil of the "Campine" district being on about a level, it is set out in ridges for irrigation, and this is effected by tapping the main courses. The comparative expenses come to about 52s. 6d. per acre. A new law on water-courses is at this moment before the Chamber. Its application will probably admit of the utilization, for the profit of the agriculturist, of those riches which are at present lost or badly employed on account of the state of the water-courses. Irrigation would then develop itself in a manner quite impossible at the present time. Sewage-water has not been used for irrigating in Belgium up to the present time. An English public company (the Belgian Public Works Company) is carrying out at this time at Brussels an important work of purification, which comprises the utilization of the sewage water of this town for the irrigation of 150 acres of meadow situate in the valley of the Senne. But this portion of the work is not yet begun, and it is likely that it will not give a good result, because the extent of the meadows to be irrigated appears much too limited for the quantity of sewage-water to be employed.

Baron Gronow, Prussia.—All over the land artificial water meadows exist, principally where small streams and a hilly or

mountainous configuration of the soil make the arrangement of water meadows after the "Trögger" system easy. The result is good where water is not wanting and the soil is not too flat. On 240 acres of water meadows in my neighbourhood where the land is too flat the result is bad, only aquatic grasses springing up.

Monsieur Bovet, Switzerland.—Water is generally utilized for irrigation as well as drainage with more or less skill in the application. Thus, in western Switzerland, irrigation is in its infancy, whilst in Aargau particularly, and several of the central cantons, it is carried out with considerable skill.

N.B.—The beet-root distillery referred to by me as being in course of erection, the locality of which I was not at the time at liberty to name, I am now permitted to state is being erected for Mr. Campbell, of Buscot Park, Berkshire, and the engineer is M. Jacques Barral, of 10, Basinghall-street, London, the son of the eminent French agriculturist, Mons. J. A. Barral, the proprietor and editor of the *Journal of Agriculture*. M. Barral, jun., has made beet-root distilleries his study, and he authorizes me to say he will be happy to give full particulars to any who may be interested in the subject.

SWEDISH FARMING AND PEASANTRY.

Mr. Jählin-Dannafelt, of Stockholm, Secretary of the Royal Agricultural Society of Sweden, who is also an eminent farmer and Shorthorn breeder, and well known to the leading agriculturists of this and other countries, thus reports on the Agriculture of Sweden.

The land in most of the provinces of this country is pretty equally divided, as to area, between large and small properties. The largest arable estates are, however, to be found in the more fertile provinces of Ostgothland, Westgothland, and Scania. Estates, combined with a large extent of forest land, may be chiefly sought for in the provinces north of the great lakes, Mälar, Hjelmar, and Wener.

It is only in the province of Scania that large farms, exclusively of arable land, can be found. In other parts of the country, with but few exceptions, farms consist of arable, meadow, pasture, and forest; the proportion of arable decreases the further one goes northwards.

In the central provinces, the arable soil is a strong but fertile clay. Here are large farms, containing 600 acres or more arable; others of middle size, from 100 to 600 acres; and many small ones, of less than 100 acres arable. The proportions of arable, meadow, and forest land in these parts may be taken as follows: for every 500 acres arable there are from 100 to 200 acres meadow, 200 to 300 acres pasture, and from 500 to 600 acres forest.

The largest farms in the environs of Stockholm consist of 3,000 to 5,000 acres arable, combined with 10,000 to 20,000 acres of pasture and forest. The smallest farms, maintaining entirely the family who till it, consist of 40 acres arable and meadow, combined with 60 to 100 acres pasture and forest.

The occupiers of very small farms have generally other resources beyond farming for the maintenance of their families.

The following table is extracted from the *Agricultural Statistics* of the year 1887.

The superficial area of Sweden is about 80 million Swedish acres (the Swedish acre is one-fifth larger than the imperial acre), of which there are:

Market gardens.....	49,059 acres
Arable and other land under cultivation	4,919,884 "
Natural meadows	3,923,828 "
Waste lands and forests	70,933,967 "
Total.....	79,826,738 "

There are owners of farms of 4 acres and under...	57,755
" 4 to 40 acres	146,819
" 40 to 200 "	22,664
Exceeding..... 200 "	2,697
Total.....	229,935

The number of tenants and proprietors cultivating farms of	4 acres or less	92,849
" 4 to 40 acres	4 to 40 acres	97,092
" 40 to 200 "	40 to 200 "	15,097
Exceeding..... 200 "	200 "	1,823

Total..... 206,861

It must be noted that most landed proprietors cultivate their own land, also that the same proprietor may possess or work several farms.

The tenements are comparatively small, but continually increasing in numbers. A small portion of most of the farms is let off to labourers, so-called "torpare," i. e., cottagers who pay in labour instead of rent. The number of these plots "torp" at the close of 1867 was 179,034. The area of such a "torp" seldom exceeds 4 acres of arable land; but pasture for a certain number of cattle throughout the winter and the right of wood for fuel are almost invariably included. The labour due for such a plot or "torp" varies between one and three working-days per week, besides a certain number of day-work done by women at harvest. On many farms such "torpare" furnish a large portion of the labour required.

The average money rent of small farms, where the land is of medium quality, is about 17s. per Swedish acre, and of large farms 11s. to 13s. per Swedish acre. The rent of the best quality land varies from 17s. to 35s. per Swedish acre, and for land of inferior quality 6s. to 11s. per Swedish acre. These rents are for arable and meadow land, but pasture and forest land are almost invariably added in the proportion already stated at a nominal rent, except when timber is sold. Rents are generally estimated at 5 or 6 per cent. of the fee-simple.

In Scania (the most fertile province) arable land fetches from £16 to £20 per Swedish acre. In other provinces from £8 to £16 per Swedish acre. In most cases pasture and woodland are included without being appraised. Should, however, the woodland be in excess of what is required for fuel, it may be specially appraised, according to its position and quality.

Small lots of land cost about 25 per cent. more than large lots.

Swedish landed proprietors have from time immemorial had the right, under certain restrictions, of subdividing their estates; recently, however, all such restrictions have been removed by the Legislature, so that this right is now unlimited.

My own intimate conviction is, contrary to that affirmed by the Government and Parliament (Riksdag), that if the subdivision of land is carried out too far, Swedish agriculture will suffer; indeed, experience has already proved this to be the case.

The abundance of small occupations induces small farmers, with insufficient capital, to purchase them, in most cases at such a price that they have no money left to farm the land properly, the result is that their profits are less than if they had rented a farm proportionate in size to the extent of their capital.

The pecuniary difficulties in which so many Swedish landed proprietors are involved, cause dejectedness, check improvements such as the times require, and render impossible that increased fertility of the soil, which would undoubtedly take place had they sufficient farming capital.

The facilities for acquiring land and the great temptation consequent thereon to become landed proprietors, create a state of things opposed to good farming, and therefore to national prosperity. It is, however, only right that I should state, that these views of mine are not entertained by the majority of my countrymen.

Leases are mostly for ten years. The crown lands, however, are let for a term of 20 years. Leases are always in writing, and seldom contain any stipulations as to cropping. It is sometimes covenanted that hay and straw may not be sold off the farm, and that no paring and burning shall take place; however, at the present time the right of selling fodder is granted, especially on farms in the vicinity of mining districts and large cities, where the sale of fodder for horses is a profitable item.

The Game Laws have been vigorously enforced during the last few years, and tended to the increase of useful game; the country is not, however, over-stocked. The abundant woodland also shelters the game and prevents it being hurtful to agriculture.

It may be here stated that beasts of prey are still very numerous in some provinces, which may be best judged by the fact that the annual value of domestic animals destroyed by them is about £3,000. The Government now grants a premium for killing beasts of prey, the aggregate of which premiums have frequently exceeded £4,000 per annum.

Owing to the extent of Sweden and its geographical position there is great diversity in the crops grown.

In the southern provinces and the islands of Gothland and Oland, grapes and walnuts ripen; the principal field crops are rape, wheat, rye, barley, oats, beans, peas, vetches, potatoes, turnips, carrots, beetroot, &c. In the central provinces, apples, pears, plums, and cherries ripen; the principal crops are wheat, rye, barley, oats, peas, vetches, potatoes, turnip, and beetroot. In the northern provinces, north of the river Dalelf fruit will not ripen; barley and potatoes are the chief crops, rye, oat and turnips in a lesser degree; the business of the northern farmer is indeed chiefly restricted to growing grass.

The rotation of crops differs according to the district and province. In the northern provinces the *one-course system* of grain every year on the same soil obtains. The *two-course system*, with bare fallow on one-half of the arable land, grain and to a lesser extent root-crops on the other half, still continues in the provinces round lake Mälär. The *three-course system*, one-third of the arable land in fallow, one-third in wheat and rye, and one-third spring crops, prevails in the southern provinces. In all these systems there is more or less meadow land attached to the farm, which produces hay.

Throughout the country, however, a more rational system is gaining ground, and in the southern provinces the following prevails, differing, however, slightly according to climate, soil, and the farmer's individual taste. It is a 6 to 10 course rotation, according to whether grass is grown during two or more years successively. For instance, on mild clay 1st fallow, 2nd wheat or rye, 3rd, 4th, and 5th clover and grass, 6th oats, 7th potatoes, 8th barley, 9th clover or vetches for green fodder, 10th wheat. On stiffer clay—1st fallow, 2nd rye, 3rd clover, 4th wheat, 5th vetches or peas, 6th barley, 7th oats. On light land—1st fallow, 2nd rye, 3rd roots, 4th barley, 5th and 6th grass, 7th oats. On sandy soil only the bare fallow is exchanged for root crops, and a shorter course generally pursued, thus—1st root crops, 2nd spring corn (barley or oats), 3rd and 4th white clover or grass for pasture, 5th rye. A good average yield per Swedish acre = 1.22 (say 1.5th) imperial acre, is as follows:

	Bush.	Lbs. straw.		Bush.
Wheat	40	4,000	Potatoes	500
Rye	40	5,000	Turnips	1,000
Barley	40	2,500	Beetroot	750
Peas	30	2,000	Red clover ...	6,000lbs. hay.
Vetches ..	40	3,000	White clover 3,000lbs.	"
Beans	50	2,000	Swedish " 6,000lbs.	"
Oats	50	3,000	Timothy grass 6,000lbs.	"
Rape	40	4,000		

The use of phosphates is increasing more and more; that of guano and Chilian saltpetre has almost ceased. There are numerous establishments in Sweden for the manufacture of artificial manures; besides which considerable quantities are imported. Nightsoil in a pulverulent form, mixed with lime, ashes, and earth, is in considerable demand. Phosphates are mostly used for root crops and rye, not often for grass. The quantity applied per acre depends upon circumstances; 2 cwt. per acre of phosphates is a fair quantity.

The depth of cultivation is 8 to 10 inches for roots, 5 to 7 inches for cereals. Subsoil ploughs, going to a depth of 12 to 15 inches, are being introduced, and will become general as the growth of beetroot for sugar is extended.

Wages vary according to the provinces. During the winter they are from 7d. to 1s. 1d. per working day of nine hours. During the summer, when the working hours are thirteen, wages are from 10d. to 1s. 8d. per day, all paid in money. Where the labourer boards with the farmer, as is customary amongst the peasantry, he only receives half the above amount. As already stated, the greater part of the agricultural labour is performed by the so-called "torpare," who are paid by an allotment on the farm. Land having recently risen in value, the "torpare" system is not found economical, and it is becoming the practice to employ married servants, who reside on the farm, and are paid partly in money and partly in rations, It

may be assumed that the yearly wages of a farm labourer reduced to money are from £17 to £22, according to the province. In this part of the country (about Stockholm) the annual wages of a labourer are £10 in money and the following rations:

	2 cubic feet of	Wheat
26	do.	Rye
12	do.	Barley
8	do.	Pease
20	do.	Potatoes
0.2	do.	Milk per diem
200	do.	Wood

and sufficient land to cultivate about 10 cubic feet of potatoes. This suffices for the maintenance of a family with two or three children. If the family increases the wife and elder children must work. Farm labourers engaged by the year receive nothing extra at harvest, but day-men receive extra pay, and there is an increase in rations. Women are employed in the summer, and receive about half as much as the men. Children are also employed, and paid according to their age and ability. Piece-work is increasing on the larger farms; it is confined to draining, weeding, raising fences, chopping wood, getting in root crops—mowing and haymaking: Reaping, harvesting, ploughing, sowing, and harrowing are done by time.

The supply of labour depends upon local circumstances and the quality of the harvest. When the yield is small wages are low and hands are many, but during and after favourable years the contrary is the case. In general, agricultural labour is sufficient; in many parts, indeed, superabundant. The superfluity is taken up by the mining industries and wood-felling, for which higher wages are paid but greater exertions exacted.

Wages have increased during the last 25 years at least 25 per cent.

Hired farm labourers have always a cottage rent free. As a rule several families live in one house, having separate rooms. The "Torpare," or such labourers as are allotted land in exchange for their labour, have always a separate cottage. As a rule every married labourer has a small plot of land allotted to him rent free.

The contagious diseases amongst cattle and sheep are most rare in Sweden, owing to the very strict laws which entirely prevent, or to say the least, render exceedingly difficult, the importation of cattle and sheep, as well as their hides and wools, from countries in which such diseases prevail. Cattle-plague is unknown. Foot and mouth disease has not appeared for the last twenty years. Pleuro-pneumonia only once, about ten years ago, in a herd of cattle imported from Scotland and Norway. As soon, however, as the disease was discovered, the whole herd was slaughtered on the spot! Foot-rot and small-pox in sheep are diseases unknown in Sweden. The importation of cattle, sheep, &c., from countries in which cattle-plague has raged, is altogether prohibited for a whole year after its disappearance in that country. Cattle, sheep, &c., imported from countries in which foot-rot, foot and mouth disease, pleuro-pneumonia, or small-pox is raging, are subjected to a rigid quarantine.

Our poor-laws compel each parish to support its own destitute or disabled poor. A rate is levied upon each tax-payer in proportion to the property or income-tax he pays to the State. The contribution of the whole country for the support of the poor amounts to 1s. 1d. per head of the entire population; the aggregate is £200,000, the paupers being, of course, deducted. Of this tax about 10d. is paid by each country resident, but 3s. 1d. by each citizen. The tax paid to the State by landed proprietors amounts to about 1.20th per cent. on the assessed value. Tenant-farmers pay 1 per cent. of their assessed income from their farms. In the capital where I reside, the poor-rates paid by landed proprietors and tenants amount to about 40 per cent. of the taxes paid to the State. The excessive burden of poor-rates upon communities, increased through the claims of those able to work and other causes, has called forth much discontent with the laws; the present law which admits the claims of individuals still able to work being able to claim relief, has been repealed by the last Parliament, and only awaits the sanction of Government.

The new law does not recognise the absolute right of individuals to obtain relief from the parish poor rates, unless they be insane, or destitute orphans under the age of fifteen;

paupers disabled by age, lameness, illness, or other causes, may obtain relief, provided the parish poor board think it right to grant it. Roads and bridges are maintained by the landed proprietors, but their contributions, being in labour and material, are not easy to estimate. There are no tolls or turnpikes.

The punishment of crime is paid by the State.

The church and clergy are supported by tithes, or a rate upon the land; it varies according to localities, but is not a serious item.

For State taxation, land is divided into different classes, on which taxes, differing considerably in proportion, are levied. Taxation differs considerably in the different provinces. The basis of State taxation is the so-called "mantal," that is the area upon which a household engaged in agriculture and cattle-breeding may be maintained. The original "mantal" differed considerably, but in the course of time have become further altered by cultivation; it is therefore difficult at present to produce a trustworthy standard for comparison; one of the heaviest burdens upon the land consists in the support of a large number of army and navy pensioners.

Elementary education is accorded gratis in the Public State Free schools. For the support of these schools a national school rate of about 6d. is levied on each male above the age of 15, and about 3d. on each female. Besides this, a tax,

adapted to the wants of each parish, is levied upon each tax-paying inhabitant thereof. In the district to which I belong, this tax amounts to about 60 per cent. of the property or income-tax paid to the State. Besides these contributions, considerable sums are granted to the schools by the State, and no expenses likely to conduce to the spread of useful knowledge are shunned.

The attendance of children at school is compulsory. Parents are bound under legal penalties to see that their children go to the schools; when requisite the children receive the necessary food in school. The obligation to attend school commences at the age of 7 years, and continues until the children have acquired the minimum of knowledge prescribed by the laws. They generally cease their attendance at the age of 14 or 15. There is no law which prohibits the employment of children in agriculture before having attained a certain age. There is such a law for factories. Children go to work upon the farm as soon as they leave school. The *métayer* system is unknown in Sweden.

The transfer of land, although controlled by the law courts, is very simple and easy; the legal expenses seldom exceed 1 per cent. of the fee-simple.

Irrigated meadows are common in the northern parts of the country where rivulets abound. The result, dependent upon the quality of the water, is as a rule exceedingly favourable. Town sewage is not yet used for irrigation.

INOCULATION AS A PREVENTIVE OF PLEURO-PNEUMONIA.

The Tyrant of old sought to encourage the patentees of a new pleasure; but in these utilitarian times we exercise our invention through more commendable channels. We seek to develop new industries, new agencies, and new remedies. We combat continually in our every-day life the despotism which declares there shall be nothing new under the sun. On the contrary, we exist rather with a faith in all that the novel and strange may do for us. The mere precedent of practice is more to be defied than respected; and a man, to command attention, should talk of doing something that no one ever did before. The farmer is especially open to such influences, as, if occasionally he has been somewhat slow in action, it has certainly not been from any want of prompting amongst those who have been anxious to set him going. Often enough, however, he is quite willing to go with them, a disposition that he is evincing at this very moment. With regard to one of the agriculturist's chief difficulties, the mortality amongst his stock, if rinderpest cannot be cured pleuro-pneumonia may, or better still, altogether averted. The last new thing under the sun is that inoculation is your only true panacea; in order to thoroughly eradicate the disease this is the operation to which our breeders and feeders must resort. And to this they very dutifully resort accordingly. A deputation has been sent to London, and an inoculation trial is about to take place in Cheshire, as we believe another has been arranged for in Norfolk.

But still there is nothing quite new under the sun. If, as the learned say, we import our ills, we can also import the correctives. Inoculation has, it seems, proved singularly successful on the Continent, and therefore it is only right and reasonable that deputations should be started and inquiries instituted. But, alas! again there is nothing new under the sun. These deputations have been started, and these inquiries have been instituted. It is now close upon twenty years since that Professor Simonds, at the instance of the Royal Agricultural Society of England, went to Belgium, where he not only watched the "cases" of other Professors, but took cases under his own especial charge, whereby to prove the value of inoculation as a preventive to the

spread of pleuro-pneumonia. And these are the conclusions at which, after a prolonged and careful investigation, our representative of the English schools arrived: "That inoculation of cattle, as advocated and practised by Dr. Willems and others, is not founded on any known basis of science or ascertained law with regard to the propagation of those diseases called specific. That pleuro-pneumonia occurs at various periods of time, after a so-called successful inoculation. And, lastly, that the severity of pleuro-pneumonia is in no way mitigated by previous inoculation, the disease proving equally rapid in its progress and fatal in its consequences in an inoculated as in an *un*-inoculated animal." This is tolerably strong, the more particularly when collated with the elaborate Report upon which such an opinion is grounded. But then, as we have said, all this happened some twenty years since, and in the interim the theory may have been improved upon or perfected, either at home or abroad. After Professor Simonds, certainly the most practical authority in this country, would appear to be another member of the Veterinary College, with whom the Cheshire deputation very properly sought an interview, that they report in this way:—"Mr. Priestman supplied us with a list of fifty-seven names of persons for whom he inoculated 4,515 cows from the year 1858 to 1863, and many cattle-keepers, he informed us, practised the operations themselves in their own stocks. On the other hand, he admitted that some cows took the disease after having been successfully inoculated, and that some died from its effects. The proportion of deaths was difficult to state, he said, as the rule with them was to sell their cattle to the butcher as soon as attacked." There is certainly not much in this, neither is there in the evidence of the cow-keepers by whom Mr. Priestman was chiefly employed. According to the Cheshire deputation, "the opinion in favour of inoculation was evidently given more as an expression of hope and of feeling than of direct testimony from actual experience. They resorted to it on a first attack of the disease, but as a rule did not inoculate so long as their stocks were healthy. When asked why they did not inoculate all their cows as soon as they

came into their possession, or when they were quite free from disease, as a safer precaution if their theory was correct? they answered, "There was always a risk of some cattle dying from the effects of inoculation, and they thought it best to let well alone." Still, it must be ever borne in mind that the theory is of foreign rather than of English growth, as, moreover, it has manifestly so far taken but little root in this country. Hence all the greater necessity for tracing it home, as we believe Professor Simonds did most efficiently some twenty years since. Now, however, after some very recent experience, another good authority, Mr. James Howard, the member for Bedford, writes thus:—"All I can say is, that many sound, practical farmers in Belgium, Germany, and France seemed to place much faith in the practice. M. Dumont, of Fleurus, Belgium, is quite an authority in that country. On his farm I saw a considerable number under inoculation." Nevertheless, as his letter runs on, Mr. Howard himself would not promise to place much faith in the practice:—"I have suffered much upon my own farm from pleuro-pneumonia, and hence I strongly urged on Mr. Forster before the introduction of his Bill the necessity for dealing with this and the foot-and-mouth complaint, as well as making provision for rinderpest. I agree with you that the only plan to rid the country of this ruinous disease, pleuro, is combined exertion to stamp it out." This is bringing us back very much to where we were. Still, of late years inoculation has been much resorted to abroad, and if on the Continent it is spoken of as "a sovereign remedy," it is only fair that we should once more cross the Channel and ascertain its effects, as Mr. Howard has hardly supplied us with such material data.

According, then, to *The Veterinarian* for January: "If we take the Continental view of the subject, the prospect is not all sunshine. In Germany, Belgium, and Holland the operation is extensively practised, and the faith in its efficacy is unbounded; but we have not yet heard that pleuro-pneumonia has been exterminated in any of those countries. Perhaps we may be more fortunate here; but it seems rather odd for us to get into a state of excitement in favour of a practice which originated, and is most supported in those parts of the world whence, as we persistently assert, animals are constantly sent to us infected with the disease, which, if the theory of inoculation is worth anything, should have been long ago eradicated." Of course this is the awkward part of the whole story; we continue to import the disease from countries where, properly speaking, there should be no disease whatever. To promptly eradicate pleuro-pneumonia we must resort to inoculation, as practised in Germany, Belgium, and Holland, where pleuro-pneumonia has *not* been eradicated. It would be well for the present to confine the argument as directly as possible to this point; although, of course, a variety of collateral issues might and have been raised as to beasts generating or developing disease on their travels, and so forth. Sufficient be it here to ascertain whether inoculation has eradicated pleuro-pneumonia in the stay-at-home stock, in the homesteads of Germany, Belgium, and Holland? In Sweden, according to a further supplement to Mr. Howard's paper which we give to-day, pleuro-pneumonia never showed itself but once, the immediate remedy being the slaughter of the whole herd.

We confess that we have little hope of the results about to be reached in Cheshire and Norfolk; but if these experiments are to be worth anything, we do trust that those who undertake them will do so only after having thoroughly studied the Reports which Professor Simonds addressed in 1852 and

1853 to the Royal Agricultural Society of England. These papers furnish a very useful guide as to how such trials should be conducted, as well as to how far they can be trusted. It may be, that from the outset the Professor put but little value upon the theory, whereas the Cheshire committee would look to set about the business in a far more sanguine spirit. This feeling might of itself tend to render the investigation not so searching as it should be; but with the *Royal Journal* at hand the Professor's objections, doubts, and more decided protests must be met and overcome to make the experiment ever "worth the candle."

"In treatment," says Mr. M'Combie in a lecture he delivered only a year or two back, "I have no confidence, having tried everything that could be tried and completely failed." Still, a little further on he admits "Mr. Sorely [and I were brooding over this state of matters, when I asked him whether he could do anything to save the herd. He said, 'I will think over it till to-morrow.' He came on the morrow, and seven successive evenings, and administered to each animal a drench, and he would trust no one but himself to do it. I believe there were three changes of medicine; not one animal which got the medicine took the disease, although they had been standing in the midst of it. There was one worthless old milk cow amongst the others that I did not think it worth giving the medicine to; she took the disease, and was fed with gruel for fourteen days, and recovered, while the others continued in perfect health." Is there anything so satisfactory as this in all the evidence on inoculation? And when the Cheshire committee has got through its work in that way, would it not be as well to start another deputation for Tillyfour?

TITHE COMMUTATION. — SEPTENNIAL AVERAGES.

TO THE EDITOR.

SIR,—As many of your readers may feel anxious to know the result of the Corn Averages for the seven years to Christmas, 1869, published in the *London Gazette* of this evening, viz.:—

			s.	d.	
Wheat	6	3½	per imperial bushel.
Barley	4	6½	"
Oats	2	11½	"

I beg to state for their information that each £100 of tithe rent-charge will, for the year 1870, amount to £104 1s. 4d., or nearly 4 per cent. more than last year.

The following shows the worth of £100 tithe rent-charge for the last seven years:—

For the year 1864	103	3	10½
1865	98	13	10½
1866	97	7	9½
1867	98	13	3
1868	100	13	8
1869	103	5	8½
1870	104	1	0½

The average value of £100 tithe rent-charge for the 34 years elapsed since the passing of the Tithe Commutation Act, is £100 19s. 5½d.

I am, Sir, your most obedient servant,

MONTAGUE MARRIOTT,

Editor of "Willich's Tithe Commutation Tables."

26, Montpelier Square, 4th Jan., 1870.

THE NEW FARM.

A fearful gusty (clearly a *feminine*) wind blowing! Went on the river with my youngest born; glad to get off again. The waves ran half-a-yard high, and the savage tempest blew so lustily! twice the mast was unshipped, and the little craft heeled over far more than pleased me. By myself I should have persevered, but I didn't like to risk the life of little Benjamin, who sat wet, but calmly unconscious of danger, with the tiller-ropes in his tiny hands, as I attended to the sheet and an occasional oar. Several lots of partridges rose along the bank in places. How odd that they should choose so cold a fair on so boisterous a day! taking the air, I suppose, as ladies after the season on the Brighton strand; and the swans, too—four of them—for one has chivalrously detached himself, and taken up with a lonely maiden some eight miles lower down the river than this (her former swim was ruthlessly murdered by some boys last year); they sailed about our craft so contemptuously, and saw us off, or rather off and on again, for we were driven ashore. I don't know how often during the first half-hour, ere we got off, by force of wind and current. How oddly they strain their necks out to meet a gust! One could not help remarking it. It is so inellegant in so graceful a bird. I suppose it enables them to expose less surface to the impulse of the wind. As we could not ascend the stream, the little chap on landing made a merit of his mishap, and emptied his pockets of his biscuits, which he threw in morsels to the grateful birds, who, after much alobbering and sucking, to soften, I presume, the too hard outside, finally disposed of the floating feed.

This reminds me that the tomtits are in luck, and the linnets as well, for the Indian corn, which one fancied was, from its weight, proof against their purloining, having been soaked in the rain, they get in holes and corners and against stones upon the walk thereby speedily managing to scoop the contents of the berry at a destructive pace. All I can say is the pheasant must look out and feed faster.

Oh! such sadness pervading the whole household; the dear, old, pet terrier, Vic, is no more. For some weeks she had been evidently ailing. She had also an excessive weeping at the eyes. She seemed to have caught cold through sleeping out one severe night on a mat by the lodge-door. She had been jealous, too, of another dog which had been imported into the school-room, so for some weeks she honoured me in my study with her presence, and used to sit so prettily gazing into the fire, with her head upon her paws on the fender. To the last she tried to follow the children about, but had to be carried home one day, and another afternoon she was found lying on some hay under the rick quite chilled. A little girl carried her in, and carefully tended her; but all this I did not know until afterwards. When, however, the household became aware how seriously ill the old pet was, we had her put into a hot bath, and tenderly packed in a hamper before the fire. I got up early, before the servants were stirring, to see her; and although evidently in much pain, it was quite touching to watch the sad expression of her peculiarly melancholy brown eyes as she laid her head on one side against the hamper, and seemed to be saying a long good-bye. She did not long survive, and it has cut us all to the quick. One does not know the value of a pet, to which tender associations cling, until we lose it. We had her stuffed,

but the eyes were so great a failure that we have banished the case from the house, preferring the image that lies of her upon our mental mirror.

We have been unfortunate, too, with the steam-engine. We had an idle fellow imported to put it up, who, after three-weeks' work, finally got the boiler so fixed that we cannot keep up steam. The worst of living in the country is that we cannot get skilled workmen to carry out our plans, and "city mice" introduced take upon them so many airs.

This will end in the apparatus being sold again, and the horse-tackle being reverted to.

To return, however, to the spot I always delight in—the river bank. When compelled to strike our sail and drift down home, I took the opportunity of testing the action of my precious jetties, and steered by the bank down. Quite smoothly the water lay within them, although so rough outside. (I find everybody asking me about them now, for their unexpected success is a puzzle.) So thoroughly effective is their action, that I could not get my boat near the bank. Acting as a buffer to the current on which we drifted, they would have nothing to do with us. I shall be so glad when the spring has come, and consolidated the new earth upon the slopes with well-rooted grass. We shall then be beyond the reach of tremour.

How odd it is that, despite all the wet we have had lately, the springs have not "come home" yet. The well that supplies the kitchen-range is lower than it was in June.

"As the days lengthen,
So the springs strengthen,"

is an old, and I suppose—at least from my own experience—a true adage. Why it is I don't know. One would think that if a fair tap were flowing in June, that an October soak would sufficiently re-supply the vessels. In practice it is not so however.

Alack-a-day! Since writing the above (for one stuffs this pie at odd hours as occasion serves), such a dire flood hath invaded us, or rather a tremendous reduplication of floods—one yet more angry over-riding another. Such an onset of waters has not occurred in this valley since 1852, bearing along with it a spoil of all sorts from the upper country—dead carcasses, and gates, and mighty trees, and in one instance a set of steps belonging to a church ten miles above us, that is built upon the bank. The boatmen were driving dangerously in their punts backwards and forwards all the daytime that the light lasted, fishing out the waifs and strays. One night before the flood arrived at its highest I got a moonlight stroll beside the rising waters. The dense, dirty volume had been visibly swelling for hours, and was just beginning to over-spread the meadow along its immediate margin, beside making insidious inroads by every hollow spot and ditch. I had some colts out, which I did not want drowned; so merely changing one's dress-boots (we had just returned from the warm shelter of a festive drawing-room—a very different climate to that to which the colts were submitted), and throwing on an Inverness cape, I hurried down to see how far it might be safe to trust the night, as our head servant, who is a stranger to these parts and not yet used to the river's vagaries, had not thought fit to have them moved, and it struck me as hard lines to disturb at such an hour a zealous man. Well, I

hurried down, and was enraptured. The long grass on the orchard slopes, kept as rowen for the ewes and lambs in spring, rustled quite crisp under my tread, for the air was frosty, and when the moon shone—a brilliant all but full moon—each blade glistened with a coronet of diamonds. Then the river, when I reached it, lay in a lovely lagoon, so calm, so lustrous, so lovely reflecting at once each twinkling star—the dark hanging woods and sharp cut cliff. So calm is the pool that I doubt its advance upon the meadow, and have to watch by the light of the moon, where it is nevertheless most determinedly though sily stealing on through rootlet and mould-heap. You can tell the fact only by watching the gradual disappearance of some glistening leaf as it is swallowed up, or the movement of some floating twig; and our boat there—she who played us, as I have recorded, so nearly false—floats gaily and indifferently buoyant on the surface of a flood, which though so treacherously still upon the one side, upon the other pours along, swishing surlily with a deep smothered sound suggestive only of suicide.

But how after all did the jetties answer? Perfectly. And how did the newly-made banks hold? Excellently,

so long (I am bound to record all my experience) as the flood did not rise above the top of the stone, where it is built into the land. Not an atom of the newly disturbed soil gave way until then. But when the angry waves surmounted the uppermost stones and over-ran the whole plain, then, resenting the obstacles to its progress, it did wash off a good part of the softest mould, accumulating however a quantity at the bottom of the river between the piers. So that after all, I am upon the whole rather a gainer than a loser. Where I had tarred the slope it did not suffer. It was only where the holes had been filled with soil and sown too late in the season for the grass to gather root. I am rapidly repairing the damage with a paring plough, taking off the rough surface of some inferior sward, which I beat and peg down, and which I propose to overlay with close small leaved twigs, which old Melon has been trimming off the avenue, stuck in flat and closely like the feathers on a pheasant's breast. Over this the water will glance, as I know by experiment already made. Next year I shall raise the jetties a foot above the mainland, and then no harm can possibly occur to the bank.

VIGIL.

THE CULTURE OF THE BEETROOT.

[Note on a new method of cultivating and increasing the productiveness of the soil; forwarded from the Secretary of the Board of Trade.]

Of all cultures, the one which yields most per acre is that of the beetroot. But with the methods that have been in use down to the present time this culture is extremely exhausting, as it draws off from the soil potash and other chemical substances to an extent sometimes amounting to five per cent. of the weight of the beetroot. Where this kind of culture is carried to a high degree of development, landowners usually try to repair the loss of alkali sustained by the soil by means of chemical ingredients. Independently, however, of the great expense incurred and minute care necessitated by this system, great uncertainty generally prevails as to the proper proportion of chemical substitutes to be infused into the soil.

Now I am able to state that a method at once more rational and more economical has been employed for six years, and has been attended with the most favourable results, inasmuch as the beetroot has not only been cultivated for six successive years on the same soil, but the soil itself so much improved as to be worth double its former value. Thus this new system, far from exhausting the soil, may, on the contrary, be employed—1st, in the cultivation of land, the subsoil of which contains clay covered with a sterile layer of one metre; 2nd. The value of the land is enhanced, or at all events a larger yield will be obtained. I have seen a trial field of about fifty English square rods on which beetroot has been cultivated without intermission for six years without any inconvenience having been experienced from insects. Its produce has uniformly been six tons per square rod, English measure. The system consists in restoring to the soil all that has been taken away by the culture of beetroot, its elements, viz., carbon, hydrogen, and oxygen, being constantly carried off into the inexhaustible receptacle of the atmosphere. The pulp, being the residue from the mill, forms a very nutritious food. Instead of being aqueous, as hitherto, but a small proportion of flour and other substances is needed to make it fit for food for animals. The azotic and other elements withdrawn from the land by the sale of the cattle are restored to the soil. The residue left in the still is conducted over the soil by a system of irrigation which restores to the land in the precise proportion required the alkalis contained in the beetroot. The beetroot requires in the subsoil a large amount of

alkalis, which would become troublesome if the plant were intended for the manufacture of sugar, but which are quite innocuous when the beetroot is intended for the production of alcohol. The implements used are simple, and much care has been bestowed for the last six years to diminish the labour, and to adapt it to the capabilities of the labouring population. The object in view may be shortly stated to be, to make the soil yield the greatest possible amount of produce, by not removing from it by sale any substances but those drawn from the atmosphere. The lands which for six successive years have produced beetroot have increased two-fold in value. An outlay for working material of £4,000 sterling would permit the advantageous application of this system to a surface of 700 to 800 English acres. Five artisans and eight labourers would suffice to carry on the work, which is, so to say, self-acting. The work is done during the four winter months, which in most countries are devoted to the fattening of cattle and in-door farm-work, at a time when labour is generally abundant. This labour produces 64,100 English chaldrons of alcohol at 95 degrees. When the fermentation of the juice has once set in, it is kept up by the germs of fermentation contained in the juice itself.

To the expenses mentioned above, including labour, the redemption of capital, and the fuel, are to be added those for maintenance. Thus a large allowance being made, the manufacture of the alcohol leaves a considerable profit, which would be further largely augmented by the profits resulting from—1st. The improvement of the soil; 2nd. The fattening of cattle by means of a very rich food.

All that I have stated above is based upon experiments made on a large scale for more than six years; and I would gladly undertake the introduction into England of the same system, provided those who take an interest in the matter would previously come over here in order to satisfy themselves with their own eyes as to how completely the theory here stated has been justified by the practical results obtained.

Brussels, the 22nd November, 1869,

(s.)

G. M. KARRIE,
Civil Engineer.

THE DEVONSHIRE LABOURER.

At the dinner of the Devon Central Chamber of Agriculture, on Jan. 19th, at Newton Abbott, Canon Girdlestone said: I am now about to speak a few words of myself personally and individually, though not, I hope, egotistically—for myself, then, the tie that binds me to the land is not merely of a public nature; it is also domestic. For centuries past my family have held, and now hold, land in the county of Norfolk, and though, as the youngest son of a youngest son, I was of course sent forth into the world to seek my fortune, still I passed my childhood amidst, at that time, the somewhat rude ploughs and harrows of that now most magnificently cultivated district. I have still the same connection with the land. It is not, therefore, simply that I feel—though I do strongly feel—that the laity are the bone and sinew of the church of England, and that it is in their, at this eventful crisis, taking up their proper position, asserting their own rights, and not shrinking, however troublesome it may be, from their own responsibilities, that depends, at this time, the church remaining in reality, perhaps even in name, the national church—a church opposed to priestcraft, as I believe, and favourable, as I believe, to free intellectual inquiry, and the development of civilization and improvement. But, over and above these considerations, my own special and particular sympathies are, by birth and education, not merely with the laity, but with the landed interest. I therefore say it was with great pleasure I received the kind and courteous note from your secretary with an invitation from your committee to be present at dinner with you this day. I hope I may not be presuming too much in speaking of your invitation as partaking somewhat of the nature of an olive branch. All I can say is this, that if I am correct in the supposition, I am as anxious to accept the olive branch as you can be to offer it. If, sir, there have been some hard words passed—if I have sounded the alarm perhaps rather too loudly for some sensitive ears—if there have been faults on either side, and generally there are faults on both sides, then I say let us forget it all, and in the old familiar language “let bygones be bygones.” If you should think fit to make me a member of your Chamber, all that I can say is that I will work with you and for you with heart and soul for the common weal and the common good. When two Arab chieftains meet, however bitterly opposed they have been before, if once they have broken bread and eaten salt together, it is the same as if they had sworn eternal friendship. Now, you members of the Chamber—landowners and farmers—you have broken bread at this table this day with the Vicar of Halberton; and I say, gentlemen, let us swear eternal friendship from this moment—friendship, not for any selfish end—friendship, not for any particular individual advantage—but friendship for the purpose of promoting to the utmost of our power the common weal and prosperity of all classes. For it can't but be as plain as plain can be—that there can be no prosperity to any class unless there is sympathy for all classes one with another. It is when the landowner, and land occupier, and labourer, and, as the Chairman said, the poor “passen” himself, are all agreed and united together, that we shall arrive at the common weal and prosperity of all. This county is one, as we here all well know, of many honourable and glorious traditions—traditions of war, of art, of commerce, of trade, of manufacture. I, for one, as a man of peace, cannot express any wish that our glories in war should be renewed. I wish most anxiously that all the future victories of this country should be marked not by blood, but by the peaceful trophies of education, improvement, enlightenment, and civilization. Let us then unite for that which is the greatest and noblest mark for all of us to aim at—the improvement of the social position of everyone with whom we move and mix. With a long pull, a strong pull, and a pull altogether, let us unite to do our best to make this county of Devon—this county of ancient tradition and renown—this garden of England as it is justly called, with its almost Italian climate, and fertile soil—let us endeavour to make this county that which it seems to have every capability of becoming, as an agricultural county, the best cultivated in

the empire—a county in which its landlords shall be far and wide known as the most kind and considerate towards the labourer, and in the treatment of the tenant—a county in which the farmers shall be known as the most intelligent, enlightened, and enterprising of their class—a county in which, lastly, the labourers shall be spoken of as the best-fed, the best educated, the most contented, thriving, thrifty, happy, rosy-cheeked peasantry in the land.

Sir LAWRENCE PALK, M.P., said: He regretted that the Duke of Somerset and Sir Stafford Northcote were not present, but if any consolation could be afforded for the absence of such distinguished men it would be found in the splendid speech which they had just had the pleasure of listening to from Canon Girdlestone, one more replete with kindness of feeling and with better expressions of friendliness and good wishes it had not been his good fortune to hear. He (Sir Lawrence), in common with others, had thought that both in his writings and in his speeches the rev. canon had been extremely hard upon the landowners and farmers of the western counties. But he thoroughly recognised in him the same spirit which actuated all landlords, and he believed all farmers, namely, a desire to do the best they could to raise and promote the condition of the agricultural labourer, and the interest of that profession to which they are allied and which they represent. He was glad that he had one common feeling at least with the rev. canon, in which he cordially agreed with him. He could agree with every word that he had written with reference to the incidence of the Poor Law upon the condition of the labourer, and upon the taxation of the agricultural interest. He had heard it said that the agriculture of this county was very far from what it ought to be, that the landowners were unmindful of their duties, that the tenant farmer was ignorant and unskilled. He thought that was a superficial view to take, because as a point of fact he would venture to say that in Devonshire he could show as good farming as would be found in Norfolk or in the Lothians of Scotland. The agriculturists of Devon were not at the low pitch they had been represented. If they were they would see farms out of cultivation, rents falling, labourers in the deepest distress, villages in ruin, and the country in decadence and poverty. There was not a man in the room that did not know that that was not the true state of things; there was not an agriculturist that he was now addressing who did not know that year by year the breadth of land under cereal crop had increased, the quality of corn improved, and the quantity improved. There was not a man—and the rev. canon had admitted in his writings that the wages of the labourer had gradually and surely risen—there was not a man in the room connected with a Board of Guardians or a Board of Health who did not know that great improvements had been made in the dwellings of the poor, that the sanitary laws passed by a wise Legislature had been in many instances strictly enforced, and he, as a landowner, regretted that they were not more strictly enforced than they had been. It was a patent fact that the condition of the labourer in this county, especially in this vicinity, was one of amelioration and improvement. He might be met by being told that the pauperism of the country was daily and yearly increasing. He admitted that it was a sad fact; but the pauperism arose in the towns, and not in the country districts. He divided paupers into three classes—the agricultural, the urban, and the criminal; and inquired how the poor-law operated on their respective conditions? The principle of the poor-law of 1834 was simply relief from destitution, and, if rigidly carried on, it was a singularly cruel principle to apply to the agricultural poor, because it was seldom that the agricultural labourer was in a thorough state of destitution. These were times when, from illness or otherwise, he needed temporary relief; but the law of 1834 was incapable of relieving him till he had become utterly destitute, and then he must go into the union. The law was therefore useless to the agricultural labourer. As to the urban population, stagnation of trade had thrown large bodies of men out of work. The poor rates had increased from £6,459,515 in 1865-6 to £7,495,061

in 1867-8. This was a frightful increase, and where did the burden of it fall? Why, on the land; for while the annual income of the country was 396 millions, only 94 millions was assessed to the poor rates. The poor-law, then, did not benefit the agricultural labourer on the one hand, while on the other it pressed with peculiar hardship on the landed property of England; nor, he thought, could such a law be defended in any way. With respect to the criminal and vagrant class, the poor-law provided that there should be a labour test; but, practically, writers told them, the test was not applied. He enlarged on the dreadful evils that flowed from the mass of criminal population, and suggested that the younger portion—the "city Arabs"—might be made men of by being assisted to the colonies, where their bone and sinew would be useful. Meanwhile, one result was certain, the poor-rate was increasing to an extent which threatened to overwhelm property.

Mr. WADE, the Chairman, said, with respect to the land question, the position of the tenant in Ireland as to farm buildings and improvements, was different from that of the English tenants, and therefore, he thought there was no ground for the supposition that a tenant-right law in Ireland would be followed by a tenant-right law in England. He thought legislation of this kind between landlord and tenant in England undesirable. Turning to the subject of education, he could not see that practically the Factory Act could be applied to farming; and he had been, and was still, opposed to compulsory education. Still, he confessed that he had been shaken on this latter point by a cogent argument. It was stated very clearly that not more than 5 per cent. of the agricultural population were unable to read or write; but

from that per-centage a large proportion of the criminals of the country were found, and if those were the facts, would it not argue that they ought to get hold of that 5 per cent., and educate them, even by compulsion, if necessary?

Mr. ELIAS CUMMING said that he found that he had paid during his time in business £2,500 in poor's rates, besides the duty of guardian, costing him £10 a-year for many years past. Pauperism would never decrease. Though men got more wages, yet there were excursion-trains, beer-shops, and other ways by which they could spend it. The more wages some of them got, the less they could pay their debts, till now it was common to find many who paid nobody. Too much money was often a cause of drinking, and thereby of pauperism.

Mr. COULTON stated that the Canon had been mistaken as to the rate of wages. He himself paid 12s. a week in winter, and 15s. a week in summer. He was very much pained at the time to see the statements that were put forth, for they were a libel on the agriculturists of the West of England. He maintained that the labourers in the rural districts were better educated than those in the towns.

Mr. ELIAS FORD, invited Canon Girdlestone to accompany him in a visit to some neighbouring villages where he should see and converse with the labourers, and after that visit Torquay and see the labourers in that fashionable town; he would then be able to compare the condition of the two. He could agree with Sir L. Palk in saying that seldom or never was destitution existing amongst the agricultural labourers. At the Guardians' relief table that day they had pages of applications from distressed labourers in Torquay, but few from agricultural labourers.

AGRICULTURAL SOCIETIES AND ARTIFICIAL MANURES.

TO THE EDITOR OF THE SCOTSMAN.

SIR,—At the Christmas meeting of the West-Lothian Agricultural Association, a motion by Mr. Arkley, Philpston, asking the Society to grant a sum of money annually as a retaining fee to a practical analytical chemist, in order that the members of the Society may get a cheap and reliable analysis of all artificial manures, chemicals, or feeding stuffs at a lower rate than is now charged by chemists in individual cases, was submitted for discussion. Other business prevented the subject from being taken up and ventilated, and the motion was referred to the Standing Committee. The committee at its last meeting have thought the subject involved a money difficulty, and have handed it back to the general meeting to be held in the Council Chamber, Linlithgow, on Friday first. The circular calling that meeting has just now been put into my hands, and under the head of business appears a motion, "Whether any funds should be taken from the Society for a blood stallion," or for a draught horse, and "also, to consider the whole question of a chemical analyst."

I understand the committee are not prepared to advise the Society to undertake the responsibility of the latter motion, but I fear they have looked at the subject not as it affects the community or themselves individually, but in their position as guardians of the funds of the Society, and have barely given it that attention which it seems to me to deserve—in fact, I understand some of them think it might lead the Society into trouble. This is a mistake, as it can no more lead a society into litigation than the granting of a £50 premium for the best horse to serve the district can; and the advice and protection of the Association in the question of manures and feeding stuffs is as legitimate a part of the business of an agricultural society as the encouragement given to the breeding of cattle or the improvement of agricultural implements.

The question of analysis of artificial manures is one of growing interest to the farmer, and one which only collective and organized bodies can sufficiently cope with. The Highland Society, through its chemist, Dr. Anderson, have had various lectures on the value of artificial materials for feeding and manures, and which explained their properties. The Haddington Farmers' Club have also had before them similar discussions, particularly the value of artificial feeding-stuffs in the fattening of store stock; and in your Saturday's paper appears a notice of a meeting of the Kelso Club, where Mr.

Burn says "he has no doubt as to artificial food being profitable, and he thought it specially advantageous on poor land where few sheep are kept." But while this is extending their adoption, it is not preventing but rather fostering and encouraging the cases of adulteration so much complained of—and certainly it has enormously increased the demand for artificial stuffs; and in your extract of date 7th, from M'Lean & Hope's report, they say: "There is a continuous active demand for all the ingredients for artificial manures, and also for the manures themselves; and the scarcity of phosphatic guano and other cognate materials is evidenced by the high range of prices and the readiness with which all offers are taken out of the market. Bone cargoes are excessively scarce, and shipments in the spring months from the Baltic and other northern ports are quoted at almost unprecedentedly high figures. The recognized value of the Highland Society and its offshoots, the local societies, as a means of improving whatever affects the interest of agriculture, by the granting of premiums and commendations, has undoubtedly changed the system of farming, and the impetus and interest of late years taken in Christmas shows of fat stock is also compelling the farmer to fall back upon artificial stuffs to a larger extent than ever, and the genuineness of the material supplied now demands attention, and, with many others, I also hold protection. The question is, how is this to be accomplished."

It is well known that the great competition amongst dealers, and the merit of being cheapest, encourage the introduction by dishonest men of adulterating materials; and how often do reports appear of disputes between farmers and merchants as to adulterated guanos, and bad oilcake often filled with the dry worthless "shellen seeds" which the miller used to send down the river, or the introduction for pure bran of that useless refuse, "used bran," the soul and substance of which has been previously extracted by the power-loom manufacturer to make "paste" or "size," afterwards caked and bought by some oilcake-makers to cheapen this otherwise valuable feeding material when genuine.

If a society can give a premium of £40 or £50 for a horse to improve the stock of a district (and some farmers of high intelligence are beginning to think that our splendid Clydesdale is, like the American Indians, being improved off the face of the earth), would the money of the association not be equally well spent in protecting the soil from being robbed, and the

cattle from being defrauded, by means of an analysis of these artificial stuffs, and thereby save the farmer the risk of losing half his crop, and certainly half his money? A case of some interest came under my observation lately. A farmer in this neighbourhood ordered some guano from a most respectable Edinburgh merchant, at £12 10s. per ton. The first Wednesday he was in town afterwards he went and paid the guano. He found on using it, he had bought too little, and sent for another quantity. This was also sown, he leaving certain rigs without any to test its usefulness or influence. Not being in Edinburgh again till the crop was a good way up, he received a note by post of his second purchase. The farmer by this time was getting anxious about the fate of his crop, as there was no perceptible difference between what had got the guano and what had not; but, not resting satisfied with his own judgment, he called in two of his most skilful neighbours and got their opinion. They were equally at a loss to distinguish the difference. He now complained to the merchant, and got him to send a practical man to examine the crop, with the like result as already mentioned. It was so unaccountable that the merchant would not allow any reduction, and threatened legal proceedings. The farmer was unwilling to pay in full, and equally unwilling to go to law, so he caused his men to produce the sacks in which the guano had come to him. He made up a good breakfast-cupful and sent it to Dr. Stevenson Macadam, who analysed it, and sent a report of the value. From this it was proved to be deficient in all the essentials, and valued at £5 15s. With this report in hand, he went to Edinburgh, the merchant being now glad to withdraw his account, the farmer thus saving himself an expensive law-suit and the price of his second purchase—for the analysis he paid one guinea. Now, what I understand by this motion is, to retain and give, say Dr. Stevenson Macadam, or some practical chemist of equal merit, a sum such as the Society can afford—let it be £50 or £100, according to the strength of the Society, and the number of members likely to apply for such analyses—so that they can have this done at the nominal rate of 5s. for each analysis, instead of paying one guinea, as at present—in other words, it is just forming

an assurance against fraud in the sale of these stuffs, without the machinery of a board of directors. And as scores of the members of agricultural societies, farmers included, are not and never will be exhibitors of stock, the protection herein afforded them will be the means of increasing the membership of these bodies.

The details of the working of this plan could be arranged in something like the following:—Say a farmer gives an order for a quantity of guano or any artificial material, which he himself cannot analyse, and of which he has doubts as to its being equal to the recommendation on which he was induced to give the order, let him, either through the secretary of his society, or, to save that official trouble, send himself direct to the chemist named by the society a sample of the material wished to be tested; but, in order to prevent fraud even on the part of the buyer, and to protect the seller, the sample would require to be taken from the bulk of the purchase within a reasonable number of days after delivery, in the presence of two witnesses, signed and sealed by them in a printed paper, which could be furnished by the society of which he is a member. The duties and risks of the society end here, as it has enabled its member to get a correct knowledge of his purchase; and any after-dispute, as to value, is between the purchaser and seller, and with which the society has nothing to do.

I believe this subject was before the Association some years ago, on a motion by Mr. George Davidson, Walton, he basing his motion on the principle of every member paying at the rate of 10s. per £100 of rent. This, however, did not meet with approval, and now, whether the other motion is adopted or not, it contains much that is worth considering. The demand for artificial materials is increasing, and their adulteration is keeping pace with their demand, as evidence the number of complaints made by farmers when they congregate at markets, and sooner or later the motion founded on something like the machinery described in this letter will be necessary for protection in this department.—I am, &c.,

A WEST-LOTHIAN MEMBER.

Linlithgow, Jan. 11.

THE TREDEGAR SHOW.

AT NEWPORT, MONMOUTHSHIRE.

"I do not recollect a Tredegar Show with which I have been more pleased," writes a good judge, who has been for years familiar with the show, and an occasional exhibitor. And it was a good one. The Shorthorns were satisfactory, the Herefords excellent, the Devons few but fair. The sows with litters were a wonderful sight, principally of the native, long, flap-eared sort, which holds its ground among the small farmers notwithstanding the beautiful proportions of fashionable, prick-eared, small, improved breeds. It is true that there is usually a dash of the Berkshire in them, or they have had a cross from the Squire's pig, more to please him than their owners. anyhow, each sow occupied one pen; and an abundant litter of about a dozen or over was such as would make the Suffolk men's teeth water. The fat pigs were good. The winner was a Berkshire, very like Mr. Stewart's sort, but bought as a squeaker for 12s. in Newport market, as the happy winner delightedly related.

The sheep were few but good. A Gloucestershire man, and a considerable breeder, said he had never seen better longwool lambs at any show. There was one exquisite Cotswold ewe in a pen of four of Mr. Spencer's, so broad and level and deep and stylish that she formed the cynosure of many eyes, but she unhappily spoiled by her extraordinary excellence the appearance of the pen, which was otherwise good.

To particularize more respecting the cattle, the yearling Shorthorn bulls were a good class. The winner, a funny-coloured, but level animal, with poor crops however, was the winning bull-calf last year, and is said to have been picked up with his dam in the Gloucester market. He is probably a first-crow, and wants the thorough-bred look of the fashionable herds. Mr. Stratton and his son as usual showed some good animals, particularly a bull-calf with a back like a

billiard-board, roan, well-haired, and full of rich promise. In the best class of the cattle-show, where every competitor was beautiful ("the best yearling heifer" class), we thought Mr. Stratton should have won; his animal had so much more real character than the winner about the head. But you cannot tell until you see them led out, which I did not. In a useful class of fat oxen, Mr. Arkwright showed a capital beast. That gentleman has got material in his hands to galvanize the Hereford breed, so wealthily-fleshed, curly-coated, and refined-looking are his show animals generally. We hope he will steer clear of the thick-hided, wiry-haired ones which some breeders persist in retaining.

Mr. Thomas, of St. Hilary (an annual celebrity), showed some excellent beasts of this breed, his bull taking Mr. Homfray's prize, for the best horned beast in the yard, for which, however, Mr. Tudge's two-year-old heifer, Manchester and Leicester Royal winner as a yearling and calf, ran him hard. She also won as a yearling at the Bath and West of England. Mr. Rogers showed the winners in the Hereford bull-calf and heifer-calf classes. It is curious that his name is omitted in the catalogue. The fat cows were ordinary, Lord Tredegar's winning animal being apparently deformed on one side. For the best pair of cows Mr. Tudge showed a well-ribbed and rich-coated, but small pair. Mr. Keever's beating him was disputed by the public a good deal, until the referee, happening to pass, had them led out anew; after which no more was said. The Hereford yearling steers were good, the two-year-olds poor.

The cart mares were fair, but not such as we have seen there before. The cart stallions were simply monstrous, misshapen beasts. If they could but get the beauty of the improved Suffolk into these great brutes, who have plenty of pluck—but

somehow or other, although two at least Royal winners have been of late years brought into South Wales from the eastern counties, they found no favour with the local farmer. The nag mares were a splendid class, the winner, Brandy, being as superb a mare as we have ever looked over. At a distance she appeared a small, handsome, well-bred, compact, but elastic specimen of the real old hunter class used 30 years since, full of bone, bred out of an active mountain-side mare, by a horse of worth. When, however, you approached her, she stood 16½ hands high. It was her exquisite symmetry made her seem small. We looked her over and over, and positively could see not a single fault. She was distinguished by a beautiful small but broad-fronted head and lustrous gentle eye, flat short legs, excellent back and loins, quarters stylish and powerful, grand withers, an astounding depth of well-rounded barrel, and she was a showy fast mover. Never has our eye rested on a mare more thoroughly good. Why she has never been at the Royal Show I wonder. Her present owner obtained her and a "highly commended" mare in the same class from Mr. Talbot, the master of the Ledbury hounds, who is recorded to have cleverly jumped a well-known brook of dangerous character upon her. This gentleman (then master of the Cowbridge harriers) had in his stable at the same time Topetall, a horse which has won for Major Barlow so much this year. Mr. Williams who owns Brandy now inherits a property which used to be celebrated for mountain ponies, his father being in the habit of using Arab and other sires as Mr. Smith of Exmoor lately did. His son aspires higher, and with success to judge from these mares and his lightweight hunter (also the winner in his class), a lengthy clever animal, far superior to the whole lot against which he competed. There was nothing remarkable amongst the weight-carrying hunters. They were a corky-looking lot, ordinary and rather lightish horses. Brandy would have made them look small. The ponies were a disgraceful collection of spindle-shanked brutes. The cobs a good class. There was a good three-year-old colt for hunting purposes shown, by Llandaff, a brother to Ely, and the trials of hunters took place on the Monday—a very "dirty day" it was. In the class for heavy-weight hunters there were 12 entries, and in the light-weight class 30; but the numbers that came on the ground for trial were reduced to 8 and 14. Col. Morgan took Mr. Cartwright's prize for entire thoroughbred horse with the varmint old screw Harcourt, although Christmas Carol, which ran second to Gladiateur for the Derby, was in the entry.

JUDGES.—For the horned stock, sheep, pigs, cart horses, and implements: W. Yeomans, Stretton Court, Hereford; G. Hitchman, Long Ashton, Bristol; and M. T. S. Winter, The Hartridge, Newport. For the thorough-bred horses and cobs: E. Bowly, Siddington House, Cirencester; Major Probyn, Huntly Manor, Gloucester; Capt. Dighton, Newland, Coleford, Gloucestershire; and H. Higgins, Woolaston Grange, Lydney.

PRIZE LIST.

Horned breeding animal selected from any in the yard.—A piece of plate, value 20 ga., T. Thomas, St. Hilary, Cowbridge, Glamorgan.

Yearling bull, North Devon breed.—Silver cup, Rev. A. Morgan, Machen Rectory, Newport; highly commended, Hon. G. C. Morgan, M.P., Rusperra Castle, Newport.

Two-year-old heifer, North Devon breed.—Silver cup and highly commended, Rev. A. Morgan.

Pair of three-year-old heifers, North Devon breed.—Silver cup, Rev. A. Morgan.

Yearling bull, short-horned breed.—Silver cup, J. Pybus, The Court Farm, Magor, Chepstow; highly commended, Lord Tredegar; commended, Lord Tredegar and Rev. W. H. Beaver, Pencraig Court, Ross, Hereford.

Two-year-old heifer, short-horned breed.—Silver cup, Rev. W. H. Beaver; highly commended, M. Hale, Cold Harbour, Nash, Monmouthshire.

Bull calf, short-horned breed.—Silver cup, J. Till, Caerwent, Chepstow; highly commended, Lord Tredegar and R. Stratton, jun., The Duffryn, Newport; commended, Rev. E. T. Williams, Caldicot Parsonage, Chepstow.

Heifer calf, shorthorned breed.—Silver cup, T. Hewer, Inglesham, Lechlade; highly commended, R. Stratton, sen., Burderop, Swindon; commended, Rev. W. H. Beaver.

Yearling bull, Hereford breed.—Silver cup, T. Ed-

wards, Wintereott, Leominster; highly commended, W. Evans, Llandowias, Uak; commended, W. S. Powell, Eglwynydd, Taibach; and R. Tanner, Frodesley, Dorriington, Salop.

Two-year-old heifer, Hereford breed.—Silver cup, W. Tudge, Adforton, Leintwardine; highly commended, W. S. Powell.

Bull calf, Hereford breed.—Silver cup, J. Morris, Madley, Hereford; highly commended, T. Thomas, St. Hilary, Cowbridge.

Heifer calf, Hereford.—Silver cup, T. Thomas.

Pair of yearling steers.—Silver cup, Lord Tredegar; highly commended, W. Williams, Red House, Ely, Cardiff.

Yearling heifer.—Silver cup, Lord Tredegar; highly commended, R. Stratton, sen., and T. Thomas.

Fat ox.—Silver cup, John Hungerford, Arkwright, Hampton Court, Leominster; highly commended, W. S. Powell.

Fat cow.—Silver cup, Lord Tredegar; highly commended, C. Duckham, Salisbury Farm, Magor, Monmouthshire.

Pair of cows, of any pure breed, in-calf or in-milk.—Silver cup, Rev. W. H. Beaver; highly commended, W. Tudge.

Bull, cow, and offspring, the offspring being under one year old, the cow being in milk, or within three months of calving.—First prize, £10, T. Thomas; second, £5, T. Edwards, Llanarth, Raglan, Monmouthshire; highly commended, W. Jones, Cefnlogell, Castletown, Cardiff.

Pair of breeding cows, in milk or within three months of calving.—W. S. Powell; commended, W. Evans, Llandowias, Uak, Monmouthshire.

Pair of two years old steers, £10, W. Harris, Llansoar, Caerleon.

Pair yearling steers, £5, W. Williams; highly commended, T. Dowle, Ifon, Chepstow; commended, W. Evans.

Pair of in-calf heifers, under three years old, £10, W. Evans.

Pair of yearling stock heifers, £5, R. Stratton, jun.; highly commended, W. S. Powell.

Ram lamb, long wool, silver cup, T. Thomas; highly commended, T. Thomas.

Four shearing ewes, long wool, £5, J. Williams, Caerady, Cowbridge, Glamorgan; highly commended, C. Spencer, Gileston, Cowbridge; commended, R. Leyshon, Island Farm, Bridgend.

Ram lamb, short wool, silver cup, G. Wallis, Old Shiford, Bampton, Farringford; highly commended, G. Wallis.

Four shearing ewes, short wool, £5, G. Wallis; highly commended, R. Tanner.

Pen of four breeding ewes and one ram, of Welsh-mountain breed, six guineas; J. Stephens, Sheep-house, Hay, Brecon; highly commended, R. Rees, Coldbrook-cottage, Abergavenny.

Pen of five wether lambs, long wool, £5, T. Thomas; highly commended, T. Thomas.

Pen of five ewe lambs, long wool, £5, C. Spencer; highly T. Thomas, and J. Williams.

Pen of five yearling stock ewes, long wool, £5, T. Thomas.

Pen of five breeding ewes, long wool, £5, J. Williams; highly commended, T. Thomas.

Boar.—Silver cup, R. Keene, Pill House, Tidenham, Gloucestershire; commended, J. Wheeler, Long Compton, Shipton-on-Stour, and J. Seys, The Craig, Newport.

Fat pig.—Silver cup, H. Workman, Coodkernew, Cardiff; highly commended, F. Jones, Castletown, Cardiff.

Boar and sow, under a year old.—Silver cup, H. Workman, Coodkernew, Cardiff; highly commended, Hon. F. C. Morgan, Rusperra Castle, Newport; commended, C. Homfray, Glan Uak, Caerleon, Monmouthshire.

Breeding sow, with litter of pigs.—Prize, £5, H. Hale, Troston Farm, Christchurch, Newport; highly commended, J. Seys; commended, J. Till, Caerwent, Monmouthshire.

EXTRA STOCK.—Highly commended, J. Wheeler.

Yearling cart colt or filly.—Silver cup, J. Williams, Llan Farm, Brecon; commended, A. Watts, Coity, Bridgend.

Cart mare and foal.—Silver cup, C. Coleman, Uak; commended, H. Williams, Llandenny, Uak.

Cart stallion, that has covered in the county of Monmouth in 1869.—Prize, W. Dukes, Groomont Wood, Hereford.

Nag mare for general purposes, in foal to, or with colt by her side, by a thorough-bred horse.—Silver cup, M. S. Williams, Aberpergwm, Neath, Glamorgan; highly commended,

W. Powell, M.P., Temple Stroud, Blackwood, Monmouthshire, and M. S. Williams.

Pony, under four years old.—Silver cup, J. Thomas, Arcade Wine Vaults, Cardiff; highly commended, J. Williams.

Cob or galloway.—Prize, W. Allen, Vaindra Hall, Cardiff. Highly commended, H. Elkington, Pembrey, Carmarthenshire; W. Thomas, Marroosa, Bridgend, Glamorganshire; and T. Evans, Market Street, Newport, Monmouthshire. Commended, R. Allen, Ty-to-Main, St. Melons, Cardiff.

Yearling colt or filly, for hunting purposes.—Silver cup, Messrs. L. and H. Thomas, Tydraw, Cowbridge.

Three-year-old colt or filly, for hunting purposes.—Silver cup, C. Spencer, Gileston, Cowbridge; highly commended, J. Williams; commended, J. L. Monfries, Pwly Pant, Caerphilly.

HUNTERS' PRIZES.

Weight-carrying hunter.—First prize, £20, J. Pybus; second of £10, C. Phillips, William IV., Newport, Monmouthshire. Highly commended, C. H. Williams, Roath Court, Cardiff.

Light-weight hunter.—First prize, £20, M. S. Williams; second of £10, J. L. Monfries. Highly commended, C. H. Williams; commended, Hon. F. C. Morgan, and J. Stratton, Chilcomb, Winchester.

Thoroughbred entire colt or stallion.—Silver cup, Hon. G. C. Morgan, M.P.; highly commended, T. F. Price, Newton Lodge, Monmouth.

HORSHAM FAT STOCK SHOW.

There was a very successful exhibition here.

LIST OF PRIZES.

BEASTS.

Fat ox or steer three years old and upwards.—First prize £7, L. Steer; second, £4, T. Child; third, £3, J. Napper.

Best steer under three years of age.—First prize, £6, J. Agate; second, £3, W. M. Stanford.

Best cow.—First prize, £5, J. Agate; second, £3 10s, W. M. Stanford.

Best heifer under four years of age.—First prize, £5, L. Steere; second, £3 10s., W. Sturt.

Best heifer under three years of age.—First prize, £5, W. Sturt; second, £2 10s., A. Agate; third, £1, H. Batchelor.

SHEEP.

Best pen of three wether sheep.—First prize, £6 Messrs. E. and A. Stanford; second, £3, A. Agate; third, £2, J. Napper.

Best pen of three ewes, that shall each have reared a lamb during the present year.—First prize, £4, E. Churchman; second, £2, Rev. J. Goring.

PIGS.

Best fat hog of any age.—First prize, £4, E. Churchman; second, £2, W. M. Stanford.

Best three fat hogs under twelve months of age.—First prize, £4, H. Hamming; second, £3, Rev. J. O. McCarogher.

EXTRA PRIZES.

BEASTS.

£3 10s. for the best beast shown as extra stock; W. Wood, (Ifield Court); second, £1 10s., R. Pronger.

A silver cup for the best beast, L. Steere.

A silver cup for the best beast of pure Sussex breed, L. Steere.

A piece of plate, of the value of £5, for the best beast shown, W. M. Stanford.

A piece of plate, of the value of £5 5s., to a tenant farmer, and best fat steer or heifer under three years of age; H. Batchelor.

SHEEP.

A piece of plate for the best pen of sheep shown in any class, Messrs. E. and A. Stanford.

PIGS.

£1 for the best hog shown, E. Churchman.

GUILDFORD CATTLE SHOW.

The annual show in connection with the Guildford Agricultural Association, was held at Guildford. The meeting was certainly the best in point of excellence, as well as the largest, which has ever taken place here. Among the fat beasts, the Devon exhibited by Mr. Hugh Sears was a capital beast, as was Mr. Smith's steer which took the second prize. There was a dinner, at which Mr. Bradshaw, of Knoles, presided. Subjoined is the

LIST OF PRIZES.

FAT PRIZES.

Fat ox or steer, not exceeding four years of age.—First prize, £5 5s., H. Sears; second, W. S. Smith; third, H. Sears.

Fat steer, not exceeding three years.—First prize, £5 5s., L. Steere; second, R. Beale; third, H. Daws.

Maiden heifer, under four years of age.—First prize, £5 5s., L. Steere; second, J. Hooker.

Maiden heifer, under three years of age.—First prize, £5 5s., G. Cubitt, M.P.; second, W. Sturt; third, W. Wells.

Shorthorn steer, under four years.—First prize, £5 5s., Mr. Roker; second and third, R. Channell.

Fat cow with a live calf.—First prize, £3, R. Channell; second, M. Marshall.

EXTRA PRIZES.

Best fat ox, steer, or maiden heifer, in either of the above classes, a piece of plate, L. Steere.

Best fat beast in either of the foregoing classes, £5 5s., L. Steere.

Best fat heifer or steer of any age, fatted and exhibited by a tenant farmer of less than 150 acres, £3, H. Daws.

FAT SHEEP.

Pen of three Down wether sheep, under two years of age.—First prize, £5 5s., J. C. Ramsden; second, G. Cubitt, M.P.; third, M. Marshall.

Pen of three maiden ewes of any breed, under two years of age.—Prize, M. Marshall.

FAT PIGS.

Pen of three fat pigs, under twelve months old.—First prize £5 5s., W. Wells; second, M. Marshall.

Pen of three fat pigs, under nine months old.—First prize, £3 5s., M. Marshall; second, M. Marshall.

LEAN STOCK.—BEASTS.

Best bred bull under two years of age.—First prize, £5 5s., L. A. Cousmaker; second, G. Holland; third, M. Marshall.

Best bred bull calf, not less than six months and not exceeding twelve months old.—First prize, £3, L. A. Cousmaker; second, G. Holland.

Best cow and offspring of the present year.—Prize, L. A. Cousmaker.

Best heifer under three years of age, in calf or with a calf.—Prize, L. A. Cousmaker.

Best heifer under two years.—First prize, £3, H. Sears; second, L. A. Cousmaker.

EXTRA PRIZE.

Best bull calf.—Prize, G. Hollands.

STORE SHEEP.

Best pen of ten pure-bred ewe lambs, under twelve months old.—Prize, M. Marshall.

Best pure bred ram lamb, under twelve months old.—Prize, G. Cubitt, M.P.

STORE PIGS.

Best boar, not exceeding twelve months old.—Prize, W. Drewitt.

Breeding sow in pig (or with her pigs), and which shall have had one litter or more.—First prize, £3, W. Wells; second, J. C. Ramsden.

MANGOLD WURTZEL.

Nine roots of long mangold wurtzel.—First prize, £2, T. Drewitt and Son; second, W. Drewitt; third, M. King.

Nine roots of globe wurtzel.—First prize, £2, W. Drewitt; second, G. Holland; third, L. A. Cousmaker. Highly commended: G. H. Pinkard.

SWEDES AND TURNIPS.

Nine roots of swede turnips.—First prize, £3, W. Drewitt; second, M. Marshall; third, J. Franks.

Nine roots of white-fleshed turnips.—First prize, £3, L. A. Cousmaker; second, L. Hilder; third, M. Marshall.

WEST OF ENGLAND FAT CATTLE SHOW.

This Show was held at Plymouth under unfavourable auspices, the weather being very wet and stormy, which much affected the attendance. There was, however, a large show of stock.

The Judges for cattle, sheep, and pigs were—J. Bult, Kingston, Dorset, Somerset; W. Paige, St. Germans; A. Parson, Highweek, Blacktorrington.

PRIZE LIST.

NORTH DEVONS.

Steers not exceeding three years and three months old.—First prize, £10, W. Farthing, Stowey Court, Bridgwater; second, W. Smith, Hoopers, Exeter.

Oxen or steers exceeding three years and three months old.—First and second prize, W. Farthing.

Cows and heifers of any age.—First prize, R. Burton, Place Barton, Broadclay; second, J. Russell, Town House, Gittisham, Honiton.

SOUTH DEVONS.

Steers not exceeding three years and three months old.—First prize, W. Coaker, Charleton Court, Kingsbridge; second, S. Huxham.

Oxen or steers exceeding three years and three months old.—First, W. Coaker; second, J. M. Toma, Coyton, Ivybridge.

Cows or heifers of any age.—J. Drew Articombe, Tavistock; second, J. Drew.

SHORTHORNS.

Steers not exceeding three years three months old.—Second prize, R. Tremain, of Trethurffe, Graupound-road.

Oxen or steers exceeding three years three months old.—Prize, J. Horswell, Burn Hall, Lew Down, Exeter.

Cows or heifers of any age.—First prize, W. Drew, Plymouth; second, E. Elliott, Landulph, Cornwall.

HEREFORDS.

Oxen or steers exceeding three years three months old.—First prize, W. R. Grose, Penpont, Wadebridge; second, G. and W. E. Lobb, Lawhitton, Launceston.

Cows or heifers of any age.—First prize, J. W. James, Mappowder Court, Blandford; second, W. R. Grose.

CROSS BREEDS.

Oxen or steers of any age.—Prize, J. Jackman, Meadwell Kelly, Tavistock.

SHEEP.

Pen of three Leicester wethers under 23 months old.—First prize, R. Nicholls, Lostwithiel, Cornwall; second, R. Nicholls.

Pen of three wethers of any other long-woolled breed, not being Leicesters, under 23 months old.—First prize, R. C. Clark, Barne Barton, St. Budeaux, Plymouth; second, R. C. Clark.

Pen of three Down wethers under 23 months old.—First prize, S. Hyne, Stonehouse; second, S. Hyne.

Pen of three Exmoor wethers of any age.—Prize, W. Smith, Hoopers, Exeter.

Pen of three Dartmoor wethers of any age.—First prize, J. Drew, Articombe, Tavistock; second, J. Drew.

Pen of three ewes of any age or breed.—First prize, T. Potter, Yellowford, Thorverton, Cullompton; second, R. Nicholls.

PIGS.

Pen of two pigs under nine months old.—First prize, E. Trood, Bowhay, Exminster; second, J. S. Davey, Redruth.

Fat pig of any age.—Prize, W. F. Collier, Woodtown Horrabridge.

LEWES FAT STOCK SHOW.

The class for oxen has always been a good feature in the Lewes Show, and there were here six exhibited. There would have been more, not only in this class but in some of the others, had the entries of Mr. Tylden Smith, of Beckley, arrived. The best ox was unquestionably that of Mr. Pennington Gorringe, of Pebsham, Bezhill, and it was of course awarded the first prize. Some fine beasts were shown as extra stock, and the market was well supplied with fat cattle.

The show of sheep and pigs was not so good as of beasts. The judges were Edward Cane, of Berwick Court; F. Tuppes, Priesthwaite, Westham; and Richard Broad, of Hurstpier-point. Their awards were:

Ox, five years old or upwards.—First prize, £8, P. Gorringe, Pebsham, Bezhill; second W. Mannington, Isfield.

Ox or steer, not exceeding four years old.—First prize, £8, Right Hon. H. Brand, M.P., Glynde-place; second, W. Taylor, Glynde, Westham.

Steer, not exceeding three years old.—First prize, the silver cup, value £10 (being the best beast in the show), W. Botting, Westmeston-place; second, J. Shoomsmith, Berwick.

Cow, four years old and upwards.—First prize, £8, J. Shoomsmith; second, W. Botting.

Open heifer, under four years old.—First prize, £5, E. and A. Stanford, Katons, Steyning; second, J. Russell, Hastock's Gate.

Pen of five Southdown wethers, under two years old.—First prize, £7, J. Walker, Firie; second, E. and A. Stanford.

Pen of three fat pigs, under twelvemonth old.—Prize, £3, T. Cooper, Bishoptone.

THE WEST HERTS CHRISTMAS SHOW.

This show, held at Watford, was on the whole very good in quality, and the number of cattle, sheep, and pigs was about equal to that of last year.

The judges were—for stock, G. Garne, Churchill Heath, Chipping Norton, Oxon; R. E. Horne, Waxwell, Pinner; R. J. Newton, Campfield Farm, Woodstock, Oxen. The prizes were as follows:

CATTLE.

Shorthorn oxen or steer, not exceeding three years old.—First prize, Mrs. W. Morten, Lea Farm, Watford; second, the Earl of Clarendon, K.G., The Grove, Watford.

Shorthorn ox or steer, three years old and upwards.—First and second prizes, Thomas Leach, Longcroft, Bovingdon, Hemel Hempstead.

Shorthorn heifer, not exceeding three years old.—First prize, the Earl of Clarendon; second, W. Jones Loyd, Langlebury, Watford.

Shorthorn cow, above three years old.—First prize, G. Stone, Cassio Bridge Farm, Watford; second, H. F. Hill, New Hall, Watford.

Ox or steer, of any breed or age (not Shorthorn).—Prize, J. Furrott, The Wood, St. Alban's.

Fat heifer, of any breed or age (not Shorthorn).—First prize, C. Waghorn, Nether Wyke Farm, St. Alban's; second, Lord Cheam.

EXTRA PRIZES.

Ox or steer of any breed, not exceeding three years old.—Prize, £10 10s., Mrs. W. Morten, Lea Farm, Watford.

Ox or steer of any age or breed, exhibited in any of the classes by a tenant-farmer residing in Herts.—Prize, £10 10s., T. Leach, Longcroft, Bovingdon, Hemel Hempstead.

Cow or heifer of any breed or age exhibited in any of the classes, bred by a tenant-farmer residing in Herts.—Prize, £10 10s., J. White, Parsonage Farm, Rickmansworth.

The best animal exhibited by a tenant-farmer residing within a radius of 15 miles of Watford.—Prize, 20 guineas, G. Stone.

SHEEP.

Cross-bred or longwool fat wether, one year old.—First prize, C. Longman, Shendish, Hemel Hempstead; second, J. White.

Fat wether, of the Southdown breed, one year old.—First prize, W. Jones Loyd; second, the Earl of Essex.

Hampshire, or other short-woolled wether sheep not Southdowns, one year old.—First prize, James White, Apple-tree Farm, Rickmansworth; second, Jones W. Lloyd.

Fat wether sheep of the Shropshire breed, one year old.—First and second prizes, Lord Cheam.

Fat long-wool sheep (ewe or wether) of any breed or age.—Prize, Charles Longman.

Fat short-wool sheep (ewe or wether) of any breed or age.—Prize, Lord Cheam.

£10 10s. for the best pen of sheep in the show, exhibited by a tenant-farmer.—Charles Longman.

£10 10s. to the breeder of the best pen of sheep in the show, he being a tenant-farmer.—Charles Longman.

PIGS.

Three pork pigs of any breed, not exceeding sixteen weeks old.—Prize, W. Jones Loyd.

Three fat pigs of any breed, not exceeding nine months

old.—First prize, W. Jones Loyd; second, the Earl of Essex. Three fat pigs of any breed, not exceeding fifteen months old.—Prize, John White.

Fat pig of any breed or age.—Prize, W. Jones Loyd.

25 5s. for best pen of pigs in the show, exhibited by a tenant-farmer.—Prize, John White.

CARR'S ANNUAL HARVEST REPORT.

ROSTOCK AND DANZIC, 31st DECEMBER, 1869.—

Regarding the PAST, we regret to say it has been "flat, stale, and unprofitable" to all concerned in the trade in general at home and abroad, prices having gone on gradually dropping from the top price, ruling in the month of June, 1868, about 40 per cent., and are now below the standard at which they ruled some three years ago, ere the rise took place, wheat being now considerably below its value to other cereals, owing to the continued large arrivals from abroad, which must have inflicted severe losses on the shippers or receivers, or perhaps on both; in fact, shipments were continually made, though a loss of several shillings per quarter was staring the parties in the face whilst shipping. The calculations of the trade for the campaign of 1867 and 1868 were baffled by the six weeks' earlier harvest than usual, and this campaign (1868 and 1869) they have been baffled by the unexpected enormous supplies. The British farmers are to be pitied, as they have been, and are still keeping back their produce in the hopes of better prices, as they cannot reconcile themselves to any other idea but that with short crops at home prices must improve, whereas it is more than probable (as many well-informed people say must take place) that they will have to bring it to market without reference to price. Be this as it may, we pity the poor fellows, and repeat the advice we gave them when Free-trade became the law of the land (in Great Britain), namely, "To grow less grain for human food (particularly wheat), and turn their attention chiefly to cattle-breeding and the production of feeding-stuffs, as they cannot compete with the foreigner in the produce of wheat;" whilst they must fear no foreign competition, at least none of great importance, for this simple reason, the cost, and still more, the sea risk being too great.

PRESENT.—The trade remains in an unsatisfactory state, owing to supplies being considerably more than what the consumption can at present digest. The mild weather has, more or less, also to do with the present stagnant position. Frost would give it a lift, as frost not only stops further shipments, but also strengthens the nerves and hopes of holders, increases the appetites of consumers, and invigorates the body and mind of buyers. It is true that stocks are not moderate; on the other hand, they are not so enormously large as many consider them to be—were they but proportionately spread over the whole of the United Kingdom, instead of their being hoarded up in a few of the leading ports (principally Liverpool and London), they would be considered light. When the sliding scale (the old Corn Law) was in vogue, and when the United Kingdom imported yearly only 8 to 4 million quarters of wheat, a stock of 1 to 2 million quarters was then thought nothing of, whereas now-a-days, when 8 to 10 million quarters are required, a stock of 1½ million quarters is considered large, and this is chiefly caused by said stocks not only being in a few ports, but because they are held by first hands (the importers or consignees); this fact, however unfavourable it may now operate on the purse and nerves of present holders, is the

surest safeguard that there is more certainty of the trade sooner or later mending, than if the stocks were in the hands of millers, flour dealers, bakers, and consumers, it being well known that said parties have for many months past held, and still continue to hold, next to no stocks, which is generally the case with them in falling markets, and still more so at this time of year. So much is certain, prices have fallen 40 per cent. from the top prices paid in June, 1868, and that they cannot fall another 40, nor not the fourth of that, and that it only requires a slight speculative demand and a week or two of firm markets, with but a slight upward tendency, to change the scene from one of apathy to one of animation; and we feel satisfied that this is just the time to try the truthfulness of the adage of an old and much respected London corn factor (we mean the late John Ashlin, Esq.), who, as he left a deal of money, must have felt the glittering force of this mode of doing business, viz.: To buy dear and sell cheap and make money," that is, to buy and sell when others *think* you are wrong and an ass for doing so; in both cases you have the market to yourself and buy and sell accordingly that to advantage. At present everyone is anxious to sell, *ergo*, now is the time to make a bargain, as it appears to us that it is not so much the fear of a further fall, but the want of suitable store accommodation, that is making importers on own account, or the receivers of consignments, to knock off their stuffs at prices which will most probably not nett the shipper (particularly the American) the cost of production to the growers. Large as have been the arrivals, they have not much exceeded what we estimate must be the monthly imports into the United Kingdom, to meet the requirements of the population therein, as, by referring to our N.B. you will find that we put down the requirements for this campaign (from the 30th August, 1868, till the 1st September, 1869), at 11 million quarters of wheat and flour, which is tantamount to 916,666 quarters per month, *ergo*, four months ending 31st this month (December) 3,666,666 quarter wheat and flour. The quantity of wheat afloat to direct and indirect ports, barring what is afloat per steamer, according to Mr. Dornbusch' list of the 18th instant, amounted to 454, against 367 cargoes same time last year, *ergo*, only 77 cargoes, or about 200,000 quarters more of wheat, which is a mere nothing when one compares the last year's excellent crop in every respect to the present year's growth, which is deficient both in yield, weight, colour, and condition, and this not only applies to wheat, but to oats, beans, and peas; and further, potatoes are not quite as they ought to be, being more or less diseased, particularly in Ireland.

AS TO THE PROBABLE FUTURE.—What we have above-stated applies more or less thereto. On referring to our N.B.'s under the various countries, you will find, that Great Britain and Ireland will require foreign aid to the extent of 11 million quarters of wheat and flour, provided the harvest of 1870 takes place as in average seasons, and nothing occurs to postpone it any length of time. Further, that the Mediterranean districts, particularly Portugal and Spain, will compete with Great Britain to

about the same extent as last campaign, also Belgium, Holland, and Switzerland will require at least their usual annual assistance. France, will remain about neutral; what she imports of wheat, she will, as usual, re-export in flour. Further, it will be seen, that the British Lion's providers, will have again to be North America, California, and Chili, which we have put down as being able to spare 8 million qrs. wheat and flour; Russia, $1\frac{1}{2}$ ditto; Germany, $1\frac{1}{2}$ ditto; Austria and her provinces, $\frac{1}{2}$ ditto; the Turkish dominions and Danubian principalities, 700,000 qrs.; Egypt, 250,000 qrs.; Denmark, 250,000 qrs.; total, 7,700,000 qrs. wheat and flour, leaving 8,800,000 qrs. wheat and flour to be made up by economy, which we fancy will be rather a difficult matter to enforce, for this simple reason, low prices generally produce the reverse of economy, namely, "wilful waste, which too often ends in woeful want, and consumers won't eat bread made from rye, barley, peas, maize, or oatmeal so long as they can get wheaten flour cheap; with low prices, not only do human beings take their fill, but all kinds of animals and fowls come on for more than their share, and thus we fear that when prices have risen to a pitch to cause consumers to pull up it will be too late. As stated in our remarks on the present, the low prices ruling just now are caused by stocks being, as it were, all huddled up at a few of the leading ports, instead of being proportionately spread over the whole of England, Ireland, and Scotland; so soon as a depletion takes place, we expect a reaction for the better. Were we the owners of grain cargoes at ports of call, we would most assuredly prefer ordering them to any good port, where we could have our property properly stored in airy, dry, and safest stores, rather than have the same landed in insecure wooden sheds. Better far pay afterwards a couple of shillings extra freight and charges (if obliged later on to re-ship for sale) than risk having one's property either totally spoiled or perhaps pilfered. With the exception of London, Liverpool, Hull, Glasgow, and perhaps Leith, we fancy there are warehouses enough to be got at moderate rates; if not in Great Britain and Ireland, the French and Belgians, and also the Dutch, will, we think, gladly accommodate grain holders, as the said countries don't appear to be overburdened with foreign or home supplies, as they are our best customers—that is, they are paying the best prices, and are buyers, particularly the Belgians; but, we repeat, we are certain there is room for more than double the quantity if properly spread over the United Kingdom; and we are convinced that those who store and look on awhile won't go far wrong; and we hear that many holders are storing, and intend waiting what the chapter of accidents, between this and summer, may bring forth. We do not expect to see great fluctuations during the winter, should there be normal weather, and nothing occurs in politics to cause the probability of an European war (of which, fortunately, there is no prospect), which, or course, would send up prices in a jiffy. On the other hand, we are of opinion that prices will go up so much as will suffice to pay the expenses of those who land the grain, instead of selling at present low rates. In spring a pause will take place, as usual at the said time of the year, provided always that the weather continues favourable, and mankind in general are at peace with each other, it being customary for sellers, but still more for buyers, to act on the reserve, in order to see what the Baltic may send off per first open weather, and they (especially the buyers) generally continue in this passive position till they see what the United States are likely to ship; but during the summer and early part of the autumn we most assuredly (even under the most favourable auspices or circumstances and prospects for the coming crops) expect a smartish rise, which will increase in intensity should

anything occur to endanger the growing crops. Prices being low, cannot well go much, if anything, lower; but, owing to their low standard, there is plenty of scope for a smart reaction upwards.

THOMAS CARR & Co.
HOFFMANN, CARR & Co.

ENGLAND.—Excellent autumnal seed time, and a somewhat larger breadth than usual sown, but owing to wet weather less (in fact for a series of years there has not been so little) spring wheat sown and more spring corn in its place, as such paid better than wheat. The winter was mild, the thermometer ranging a great portion of the time about 60 degrees Fahrenheit; and in the middle of February vegetation was very forward, many spring flowers being in bloom, and the cereal plants presented a very luxuriant appearance, strong in the stem and vigorous in blade; from that time till the beginning of April vegetation made no progress, but rather went back, but some hot weather in April gave it a start, so that in the early part or about the middle of May wheat promised to yield in every respect equal to that of 1868; from that time the weather changed, became cold and wintry, with some slight frost at night, and continued so until about the 27th June, when we had the first appearance of summer. Hardly can be remembered such a cold June; the month was characterized from beginning till nearly its end by an unusually low temperature, an absence of sun, and frequent showers of snow, and intensely cold biting winds; the wheat at that time was coming into ear (some of it was in bloom), so that it passed through that critical stage under most adverse circumstances, the cold weather had the effect of keeping it back; seldom has it been known to be so long a time in coming out; all this, in ordinary season, would have awakened fears of bread famine, but this cold weather was so far fortunate that had the plant been more forward much greater damage must have been done, though, of course, there is no doubt whatever but that the damage done by the cold weather, end of May and in June, was very great. Had it not been so, there is no doubt there would have been the largest crop on record, there being enough straw on the ground for a crop and a half. From the beginning of July the weather was all that could be desired, except, perhaps, that it was a little too forcing; crops matured so rapidly that several fields of oats and barley were cut about the 21st July. On the whole this harvest has been carried equal to ordinary seasons, and about three weeks later than that of 1868, and well harvested. The counties most favoured are Essex, Suffolk, Kent, Devonshire, Berkshire, and Somersetshire. The worst crops have been grown in Yorkshire, Lincolnshire, Norfolk, Cambridgeshire, Northamptonshire, Northumberland, and Gloucestershire; the Midland Counties and the Fens in particular having suffered most from storms and inclement weather. The quality, although there are many complaints that the wheat works weak (no doubt owing to the absence of sunshine, which produces grain more or less deficient of gluten and lessens its bread-making properties), in general considered an average, though here and there blight, rust, and smut (the latter in some districts has not been so prevalent since 1862, white wheat in particular); weight on the average 60 lbs. to 62 lbs., which is about an average weight, though 2 lbs. lighter than in 1868. On the whole the wheat crop is considered 10 to 15 per cent. below an average, or 25 to 30 per cent. under that of 1868. In Wales crops satisfactory in quantity and quality. Barley, a large breadth sown, quantity over average, but the quality considerably below last year's, which was unprecedented, being a bright straw colour, mellow, regular in size, and very heavy in weight, this year it is more steele, irregular in size and colour. Oats, larger breadth sown, yield not so good as expected, varying greatly in quantity and quality, the hot weather which set in in July did harm to the growth. On the whole a very moderate crop. Peas, larger breadth planted, owing to the misplant in clover, suffered from insects, particularly in the Midland Counties, premature ripening, in many districts a failure; in other respects peas are bulky, but not podded in proportion to their stem. Beans, winter sown, average, but spring bad crop. Potatoes, more soil planted, yield tolerably satisfactory, quality and flavour on the whole good. Turnips and mangolds various, suffered from drought, particularly in Yorkshire, on the whole not full average. Hay, large and fine crop, sel-

less better. Pastures yield very largely. On the whole feeding stuffs seldom have been more satisfactory.

SCOTLAND.—Usual breadth of land sown with autumn but less spring wheat; both grades were got well in, the early wheat suffered in many instances somewhat from fly. The summer was fine. In June some storms and wet, together with frost at night. The strong gales early in July in many situations did more or less injury, chiefly to the white wheats. Harvest commenced middle of August and progressed favourably for about three weeks, during which time a deal of the crops were secured in fine order; but in the first or second week of September the weather became unsettled, and the corn still exposed, suffered in colour, but the rain was of great benefit to the pastures and root crops. The bulk of wheat straw is good, but the ear not developed. Wheat may be called nearly an average, though about 90 per cent. below that of last year; quality and condition various: where secured before the unsettled weather, is good; but a deal, housed during the inclement weather in September, will have to remain a few months in stack ere it can come out a useful sample. The best weighs 64 to 66lbs., others 58 to 61lbs. Barley covered more than usual breadth of land, with full average quantity of grain, though deficient of last year. In the best lands the quality is remarkably fine, mellow, and plump, and will malt well; finest chevalier weighing 58lbs., fine quality 56lbs., and the lower grades from 51 to 54lbs.; condition good generally, though in the late districts a good deal carried in middling order. On the whole, barley is the crop of the season; bulk of straw fine, and it cuts up well. On the other hand, Oats are the worst crop of the season, less breadth sown, and varies much in quantity. In some districts it is a full crop, in others very poor, and in some even not worth cutting. Many stacks heated by rain, owing to their being badly covered; many have been pulled down and rebuilt: of course in such cases the colour is bad, though in some favoured districts the quality is fine; weight 44 to 46lbs., generally runs 42 to 43lbs., and lower grades 38 to 39lbs.; early saved, good condition. Beans and peas less than usual breadth planted; suffered from strong gales in July, though tolerably bulky in straw, and some of them pretty well podded, but on the whole defective, and below an average. Hay tolerably good crop, and secured in the finest condition, particularly the first cut; the second cut not so good, being checked by dry weather. Potatoes, usual breadth of land planted; about an average produce per acre, though smaller-sized, as usual, but quality is good. Turnips, early sown, much cut up by the green fly and cold nights, and some of the fields re-sown with rapeseed; the later sown (of which the bulk consists) have done well; on the whole, the crop may be taken as seven-eighths of an average.

IRELAND.—About 4,033 acres less land sown with wheat, which was got in under favourable circumstances, and in fine condition, in autumn as well as in spring. Generally, the plant stood through the winter well, it being mild and open, but in spring the plant received a check, owing to the cold weather, and on the whole the harvest was a late one. The early carrying is of fine quality and condition; the late cut is improving in stacks: on the whole, the yield is about 15 or 20 per cent. below an average, the midland counties having fared worst. Barley, much larger breadth sown, and the best crop of the season, being fully equal to that of last year. Oats, 16,867 acres less land sown; yield in quantity and quality very deficient condition; middling weight 54lbs. Peas and beans, 3 acres less sown; yield in general under average. Potatoes, 7,156 acres more planted; short of an average, generally middle-sized, quality good, and mostly free of disease. Turnips, 1,786 acres more; and 2,018 acres more land planted with mangold and beetroot; yield under average. Meadow and clover, 23,335 acres less; suffered from drought and frost, and yield deficient. Flax, better crop than expected.

N.B.—Last year there was but one opinion as to the result of the harvest of 1898; this year, variety in the yield and quality, and difference in weight and condition being the predominating feature. This apparently operates upon the mind, and causes much diversity of opinion as to the yield of 1899. Taking everything into consideration, we think we are not going far wrong in putting down the yield of wheat in Great Britain and Ireland as 4th below an average, and that, owing to diversity of quality, weight, and condition, fine wheat will be proportionately wanted; and that, in order to meet the requirements of the population and seed,

an importation of equal to (in round numbers) eleven million quarters of foreign wheat and flour will be required, namely, we make our calculation as follows: we go by McCulloch's calculation, and put down the average produce of the United Kingdom at 19,600,000 qrs. Deduct one-eighth for estimated deficiency..... 2,250,000 „

Makes the yield of 1899 15,750,000 qrs.

According to the last census (1861), the population of England and Wales were 20,068,234, added to this number 1,806,287 for increase since 1861, at the rate of one per cent. per annum, brings up the number to 21,871,521; then comes Scotland (as per census of 1861), with 3,068,394, and Ireland with 5,798,987, making in all 30,633,783, without taking into consideration the inhabitants of the Channel Islands. The consumption of the United Kingdom we take as follows:—

England, 21,871,521 of people consume 1 qr. of wheat per head.....	Qrs. 21,871,521
Scotland, 3,068,394 of people $\frac{1}{2}$ qr. per head, to be made up by oatmeal.....	2,256,720
Ireland, 5,798,987 of people $\frac{1}{2}$ qr. per head, to be made up by potatoes, maize, &c.	1,449,743
Add to this for quantity required for seed, which, according to McCulloch, is one-sixth produce ...	3,000,000
	28,417,983
Deduct from this the probable stocks of old wheat in the hands of the farmers and trade general, on the 1st September, at the outside, and in round numbers	1,500,000

From which deduct the yield 1899 15,750,000

Have to be imported from abroad wheat and flour 11,167,983 Last campaign, that is from the 1st August, 1898, until the 31st August, 1899, both included, the quantity imported was 30,110,164 cwts. wheat, and 4,266,127 cwts. flour. Reducing flour to wheat, and wheat to quarters of 500 lbs. each, the importation of wheat and flour amounted to 7,980,713 quarters. Last year the yield was large in every respect, say about 15 per cent. (or equal to 2,700,000 quarters) above an average, this year it is nearly as much under an average, and the consumption, owing to the prices being about 26 per cent. lower than last year at this time (Mr. Caird, in his ably concocted pamphlet laid before the Statistical Society of the 16th March, states "that every 10 per cent. additional price in the crop diminishes the consumption one per cent., and as bread has risen 60 per cent., I reckon a saving at 6 per cent., or a little over one million quarters on the total consumption"), will have increased 24 per cent., equal to about 500,000 quarters.

FRANCE.—The usual breadth of land sown with the various cereals, which were got well into the soil, both in the autumn and spring. The crops promised well up to the end of February, but rain in March, and partly so in April, with frost and rains, accompanied by thunderstorms in June, did harm to the young plants, destroying the early bloom, &c., whereupon the hot weather during the month of July and part of August forced the crops too rapidly forward, so that in many cases premature ripening is complained of, also mildew and smut is more or less prevalent. The wheat crop is worst in the south, south-west, south-east, and very much so in the central, but somewhat better (though far from satisfactory) in the north and north-west departments. The best crops are in the western and in the east and north-eastern districts. The weather during harvest-time being fine, the crops in general have been housed in fine condition, and the quality very good, though, for reasons above stated, the weight and colour have suffered somewhat, the weight perhaps to the extent of from one to four per cent. lighter than average. Rye is a very fair crop, and the same may be said of beans and peas. Barley is a very large crop, the largest during the last six years, quality fine. Oats a very full crop, fine quality. Buckwheat two-thirds of an average. Rapeseed half a crop. Hay defective.

N.B.—On the whole, the crop of wheat may be called 10 per cent. under an average (we calculate 93 to 94 million hectolires to be an average) in quantity fine, useful quality, and about two per cent. under an average in weight, *ergo* about 12 per cent. short in all; therefore cannot be compared to the excellent and abundant crop of 1898 (as such a crop only is grown perhaps once in 25 years); in fact it is about 30 per cent. inferior, and yet it will, together with the stock of old wheat left, which is estimated at about 18 million hectolires, we think, about suffice (if nothing particular occurs to the growing crops, or takes place in politics to cause speculations, to which the French are very much addicted, going from one extreme to the other) for home wants, which, according to the average of the last 10 years, is 96 million hectolires, in-

cluding about 15 million hectolitres required for seed. At all events, France will have no surplus to spare, though no doubt the quantity imported via Marseilles in grain will be re-exported in the shape of flour northwards as usual to Switzerland, Spain, &c.

HOLLAND.—Wheat, usual breadth sown; rye and barley about one-sixth; oats about one-third more, in consequence of the deficiency in the quantity of rapeseed, of which about one-fourth less planted. In Groningen and Friedland less rapeseed and oats sown, and more flax, as the increasing value of the latter encourages this cultivation. Seed time in general passed off under favourable circumstances. The weather mild in autumn and winter; the first fall of snow took place in February. Owing to the want of frost the crops suffered from vermin, and later on the rapeseed from frost rather severely early in March, so much so that in many places it had to be ploughed up, and summer corn suffered much from rain directly it had been sown; and again at harvest time, whilst housing, especially rye, and also wheat and barley, suffered more or less in colour, particularly barley, and wheat contains more or less smut. The weight of all kinds of cereals is about 3 kilos. lighter than last year. Wheat is about three-fourths to seven-eighths of an average. Rye moderate average, but in no respects so good as last year. Buckwheat bad crop; suffered from frost and drought. Oats tolerably satisfactory. Peas and beans ditto. Rapeseed in the northern parts one-fourth of an average; in the western districts tolerably fair. Rapeseed is being greatly less cultivated, but the cultivation of linseed is on the increase. Potatoes good crop, but here and there diseased.

N.B.—Holland this year will have to import, more or less (as usual); we fancy she will require even more foreign aid than last year.

BELGIUM.—Wheat: The usual breadth of soil planted, but, if anything, less, owing to the increasing cultivation of beet root. Seed time passed off favourably; for the want of hard frost in winter the weeds were not destroyed, thus the cereal crops in general, but in particular wheat and rye, in point of clearness, leave much to be wished for. The quality of the grain suffered more or less from rain (where not secured ere the wet weather set in), and rye suffered early in June from rain and frost; also wheat in point of colour. Wheat and oats are the best crops of the season, being a full average in yield and quality; good weight 62 to 63 lbs. and 35 to 36 lbs. respectively. Rye not so good as last year; weight 56 to 57 lbs. Barley satisfactory; weight 48 to 49 lbs. Potatoes good yield, but here and there infected with disease.

N.B.—Belgium we class amongst the importing countries, and she will require fully the same quantity, if not more, of foreign aid, as last year.

SWITZERLAND.—The cold weather in June did a deal of harm to the cereal crops, fruits, and vines. The cereal crop is scarcely even a moderate average, but quality good.

N.B.—Switzerland is always an importing country, and this season will require her customary assistance, received chiefly from Marseilles.

GERMANY.—**BAVARIA AND SOUTHERN DISTRICTS:** Wheat in general not so good in corn and straw, black ball being also more or less prevalent. Rye is very good, particularly in Upper Bavaria; in the hilly districts not so well spoken of, having suffered from frost in June. Barley a good crop in every respect. Oats less satisfactory. Hay and clover middling. Potatoes good. Hops one-fourth to one-third of an average, and poor quality. **SAXONY (Central Germany):** Wheat very moderate average—not so good as last year, being small in the berry and light in weight; rust and sprout more or less prevalent. Rye tolerably good yield, quality middling. Barley good, middling crop, but the berry is frequently found to be very small. Oats 40 per cent. short in quality and weight. Beans and peas defective yield. Potatoes middling. **BERLIN DISTRICTS:** Wheat not quite up to the mark, neither in quantity nor quality. Rye good yield in straw, but less in corn; quality very good. Barley very good; also oats in quantity, but quality not altogether satisfactory. Pulse satisfactory. Buckwheat very deficient in every respect. **TILTST AND MEKEL DISTRICTS:** Wheat and rye very good crop, though here and there smut and sprout is prevalent, and the storms in July did harm to both. Barley, oats, and peas very good in every respect; seldom has there been such a fine barley and oats crop. Linseed suffered in colour and quality

from rain, the colour being darker than last year. Flax excellent. **KONIGSBERG DISTRICTS:** Seed time in autumn and spring good; the usual breadth of land sown in autumn, but in spring more barley sown in soils which had previously been sown with rübeed and ploughed up. The crops of all kinds of cereals in regard to quantity are satisfactory, but quality middling. The crops in general stood well in autumn, 1868, but suffered in winter from bad weather. Rübeed and clover suffered most. Wheat is affected with rust; condition rather various (might be better); weight 59 to 61 lbs. Rye, quantity satisfactory, also quality; weight 57 to 58 lbs. Barley large crop; weight 51 lbs. Oats large crop. Peas satisfactory; not so tares. Rübeed half a crop; quality good. Rapeseed all but a total failure. Potatoes good. Hay and flax suffered from frost. **DANTZIG DISTRICTS:** Usual breadth of land sown with cereals. Seed got in last autumn under favourable circumstances; the young plants wintered well—perhaps too much so, and the consequence was they could not recover from the harm done them by night frosts in spring, they being too far forward. This was particularly the case with Rübeed, which had to be ploughed up to a very great extent. Wheat scarcely a moderate crop, condition and quality various, 61 to 62 lbs. being the highest weight, some weighing only 59 lbs., and a deal 51 to 55 lbs. Rye moderate average; quality and condition tolerably good; weight 56 lbs. Barley beyond a full average; quality not so good as last year. Peas very full average; quality good; weight 66 lbs.; condition good. Oats a full average; quality and condition good; weight 36 to 37 lbs. Rübeed and rapeseed one-sixth of an average; quality good. **POSEN AND PRUSSIAN POLAND DISTRICTS:** Crops various, having suffered more or less in some few districts from wind and ungenial weather, and want of hands to carry the crop when at maturity; on the whole, however, the harvest is satisfactory; the hay crop in particular is large, and a deal is being exported to Great Britain, &c. Peas are also a good crop, seldom being so abundant for years. Rye and oats ditto, though rye is not so heavy as last year, which was an exceptional one for weight. Flax good. Potatoes rather short of average. Wheat in every respect defective, though in some districts there is better quality than in others, yet even then it cannot be called good. In nearly every district rust is to be found more or less, and the average weight scarcely 59 lbs., whilst 55 lbs., and even below that, is frequently to be met with. **SILESIA DISTRICTS:** The usual breadth of land sown with cereals; if anything rather more grain and less oilseed. Seed got well in the soil in autumn, but germinated unevenly; later on, however, it shot a head, but suffered from the frost in spring; but again recovered. Spring sowing also got in well, though late. Wheat a full average; various in quality, condition dry; weight 57 lbs. to 60 lbs. Rye a full average; good quality and condition; weight 55 to 60 lbs. Barley 16 per cent. above average, quality good; weight and colour not up to expectation. Oats 20 per cent. above average; quality not quite up to the mark. **UPPER POMMERANIA AND STETTIN DISTRICTS:** POMMERANIA: Wheat satisfactory in quantity, though not quite so good in quality. Rye: Large crop of straw, but quantity of grain 75 to 100 per cent. of an average. Barley generally good. Oats far from satisfactory. Pulse more satisfactory in straw than in corn. Potatoes a fair yield, though here and there diseased. **STETTIN:** Usual breadth of land sown; if anything, rather more barley, owing to better prices; wintered well, that is wheat and rye; only in the Uckermark complaints of insects in wheat. All cereals not so good in quality; colour and condition as last year (which, however, was an exceptional one in this and many other respects), owing to the rain during cutting. Wheat and rye 5 lbs., barley 1 to 2 lbs. lighter than last year, and colour as above stated damaged by rain; but notwithstanding this it is fit for brewers, owing to its mild and mellow quality, and it is freely taken for export. All cereals bulk well in straw. **LOWER POMMERANIA (ANCLAY, WOLGAST, GRIEFSWALD, DEMMIN, ISLAND OF Rügen, STRALSUND, AND BARTH DISTRICTS):** Usual breadth of land sown with cereals in autumn (if anything a little more wheat in some districts), and well got in. Spring sowing was not quite so favourably effected, and proceeded normally through the winter. In spring the autumn-sown grain stood most luxuriantly, so much so, that it was feared it stood too rank, particularly wheat and rye, but dry weather and night frosts

prevented this, and caused them to suffer more or less, even spring corn, particularly early-sown oats. Wheat is 21bs.; barley, 1 to 2lbs.; oats, 2lbs., lighter in weight than last year. Barley got rain; therefore, light; bright colour, seldom to be met with. Wheat is here and there infected with sprout. Wheat 6 per cent. above average in quantity, quality various, but one finds often very good, indeed some excellent qualities; weight 60 to 63lbs. Rye 3 per cent. under average, not near so good as wheat, and where caught in the rain, condition poor and sprout prevalent; weight 57 to 58lbs. Barley 4 to 7 per cent. under average, quality various, suffered from wet; weight 50 to 51lbs. Oats 20 per cent. below average, suffered much from rain, straw short, quality various; weight 34 to 36lbs. Peas and tares 20 to 30 per cent. under average, mostly small, suffered from mildew and insects. Hay 13 per cent. below average. White clover total failure; red ditto two-thirds of last year, quality good. Potatoes 15 per cent. under average. Tubers not large, here and there diseased. **ROSTOCK AND WISMAR (MECKLENBURG SCHWERIN) DISTRICTS:** One-fourth more land under wheat, and one-tenth more under rye, in place of one-third less being sown with oilseeds. The usual acreage has been sown with barley and oats, one-third of the land usually sown with beans, peas, and tares, has been sown with clover. Seed time in autumn and in spring passed off well; all cereals wintered well; the sudden change to dry and not weather in April, did harm to rye in particular, and the severe night frosts in May did also harm, but more than all, the frosts in June—as the unusual weather in June not only prevented the formation of the berry or quantity, but also caused the quality to suffer from smut and rust, particularly oats; barley and peas suffered more or less in general; wheat full average in straw, 10 per cent. more in corn, quality and condition various, on the whole good and useful, though more or less sprout prevalent; weight from 58 to 63lbs. Rye, in straw 5 per cent. above average, but in corn 10 per cent. below, quality good; weight 54 to 60lbs. Barley 10 per cent. short in straw and 5 per cent. in corn, quality tolerably fair, but cannot be denominated malting barley for export, though freely taken by our brewers and distillers; weight 50 to 52lbs. Oats 30 per cent. short in straw and 20 per cent. in corn; quality very moderate; weight 36lbs. Peas and tares 15 per cent. short in straw, and 35 per cent. in corn. Peas a full average in every respect; the colour of all cereals suffered somewhat from the unusual weather and is not so lively as one could wish. Rape-seed and Rabeen about an average yield per acre and quality good. Potatoes good crop. Clover nearly a failure. Hay 40 per cent. below an average. **HAMBURG DISTRICT:** The breadth of land planted with grain is the usual, but the yield of wheat and barley exceeds to a trifling extent an average. The rain during the harvest, also the cold weather which preceded, did harm to the condition, quality, and weight, and wheat is less mealy, also contains less gluten; weight seldom 60lbs., and still seldom above. Very little wheat is to be found that is in a perfectly dry condition and free from sprout. The poorest is the Saal wheat, then comes Marks, then Brunswick, and then the Mecklenburg. Barley good yield, but generally speaking has suffered in colour and condition from rain. In some districts in the Mark the barley was housed before rain set in, and is a fine pale colour, but not mellow, and this quality finds less favour than yellow-coloured barley, as the latter is mellow and malts better; weight varies from 51 to 56lbs. A considerable part has been housed damp and has often a slight smell, but the greater portion saved and free from sprout. Rye has mostly yielded below average in quantity and quality. Oats also below average, suffered much in colour, condition, and weight; in fact, the most unsatisfactory crop of the season. Beans good in quality, but damp and soft. Peas defective. **HOLSTEIN AND SCHLESWIG DISTRICTS:**—**HOLSTEIN:** About usual quantity of land sown with grain, but less with oilseeds; wheat good average, quality and condition very good; weight 60 to 62lbs.; colour fine. Rye moderate average, partly infected with sprout; weight 54 to 57lbs. Barley tolerably good average; bold berry; dry condition; and weight 53 to 54lbs. Oats nearly average; good quality and condition; weight 40lbs. **SCHLESWIG:** Breadth of land sown with wheat, one-third less, with rye one-third more, and half as much with oilseeds. Wheat moderate average per acre; quality and condition middling; weight 60 to 61lbs. Rye full average, but quality not over fine, having

suffered from rain whilst harvesting. **BREMEN AND OLDENBURG DISTRICTS:** Crops got well into the soil in autumn and spring, but the cold summer was not very favourable for their getting a-head. Wheat (little grown in the Bremen and Oldenburg districts) full average per acre; quality, generally speaking, tolerably good. Rye suffered much in May from night frosts, and during the harvest time, from rain; under average; quality and condition, not satisfactory; weight, light Barley in the neighbouring interiors not much grown, but on the coast a deal of land sown, particularly in the soil which had been previously occupied with rape, afterwards ploughed up, and then resown with barley; *ergo*, larger than usual yield; but even this is of no great importance, as the quantity of land sown with the article, on the whole, is but trifling. The same may be said of oats; quantity and quality good, and the coast will have some to spare. Beans, good yield; quality, various. Potatoes, two-thirds of an average; various in quality. **EMDEN AND LEEK (HANOVER) DISTRICTS:** One-sixth more land sown with grain and oilseeds, but the seed had to be ploughed up and barley and oats sown instead. Wheat, best crop of the season, being 25 to 30 per cent. above an average; quality good, though a sprinkling of smut is to be found; weight, 59 to 60lbs. Rye is the worst crop; mostly carried in a damp state; weight, 54 to 55lbs.; quantity considerably below an average; will require an importation of foreign rye. Oats, about an average, but owing to the extra breadth of land sown, the quantity is a very full average, say similar to the yield of 1866, but quality not so fine; weight, 36 to 37lbs. Beans, a good average; a large breadth having been sown, but quality being soft, will require kiln drying; the quality, on the whole, not being bad. Barley not cultivated much in the districts; quality suffered from rain. Rape-seed, never known to be so bad; not enough for home use. Potatoes and hay, good. **RHINE DISTRICTS:** Wheat, satisfactory; also barley and rapeseed; rye, not satisfactory; neither quantity nor quality. Oats, various; some good and some bad; on the whole, about an average. Buckwheat suffered from the dry weather, and is only about half an average. Potatoes, moderate crop. **WESTPHALIA DISTRICTS:** Wheat, on the whole, good crop; suffered a little from rain during the harvest. Rye, moderate average. Oats below an average; suffered from drought; barley also. Buckwheat, full crop. Peas, good. Beans and tares, not so good. Rapeseed, poor crop. Potatoes, good; though here and there diseased. Clover, a failure.

N.B.—According to the official report of the Prussian Minister for agriculture, and compiled by him from 1,449 reports, rendered from competent parties in the different districts, the following is the average: Wheat, 97 per cent. of an average; rye, 92; barley, 94; oats, 89; peas, 87; beans, 83; buckwheat, 62; potatoes, 84; rape, 73; beetroot, 89; and flax, 83 per cent. of an average, and the bulk of straw is considerably better than last year. Taking the average of the last ten years, from 1860 to 1869, both included, the yield this year is, wheat, 0.06; rye, 0.04; barley, 0.05; peas, 0.01; potatoes, 0.04; beetroot, 0.01 more; but oats, 0.06; buckwheat, 0.14, and rapeseed, 0.02 less than an average. Taking Germany on the whole, we don't think she will be able to spare so much as last year (which we in our last yearly report put down to one and a half million quarters, and which has turned out close upon the mark, namely in round numbers, seven millions cwts. of wheat and flour) for the simple reason, because Stettin won't be able to export so much, owing to low prices ruling there, and the very short crops in Hungary, &c., we will, therefore, put down the probable export of wheat and flour from Germany this campaign, at one and a quarter million quarters in all.

DENMARK.—The usual breadth of land sown with cereals. Autumn seed-time effected under most favourable circumstances. Got well through the winter; being strong, the cold spring and the general cold (bordering at times on frost) during the whole summer, did more good than harm. Wheat, 15 to 20 per cent. above an average yield; quality and condition various, some having been housed in damp weather; colour good, weight, 60 to 61lbs. Barley, very full average yield, and good average quality; suffered from rain in August, which caused the colour to be rather dark, and not over fine for malting purposes; weight, 54 to 55lbs. Rye, full average, notwithstanding that it did not blossom under very favourable circumstances; quality, satisfactory; weight, 57 to 58lbs. Oats, under average; quality and condition various; a deal will require kiln-drying, having suffered from wet; weight, 40lbs.

Backwheat, nearly a failure. Potatoes, tolerably satisfactory. Hay, large crops, and of good quality.

NORWAY.—Usual breadth sown with cereals. Seed time in the southern districts took place under favourable circumstances. In the northern districts not so good, as frost and snow came early and put a stop to it. In the southern districts, rye moderately good yield in quantity and quality; weight, 56lbs. Barley, ditto; weight heavy, 34 to 36lbs., colour good. Oats, middling crop; weight, 37lbs. Potatoes, poor yield, suffered from frost. In the northern districts, crops very middling, even in November a good deal of oats uncut and potatoes unlifted—the frost did great havoc.

SWEDEN.—Unusually good crop of everything, all secured in good dry order, particularly rye, wheat, and barley, and also part of the oats. The northern districts are not quite so good, having suffered more or less from frost. Oats and rye, the two chief articles of export, the quality and condition is good, having been carried in favourable weather.

N.B.—Scandinavia has this year been blessed with good crops; Denmark will have more than usual to spare of all cereals; Norway, in consequence of its being a mountainous country, grows but little grain, the chief produce being grass and other feeding stuffs, thus little grain (except oats, of which a portion can at times be exported), in fact not sufficient for home use and imports yearly, more or less, particularly rye, which is the customary food, and barley, which is used by our large brewers; and last of all, peas, but less of wheat and beans, and no maize. This year the southern districts will require considerably less foreign aid than usual; the northern will require fully the usual aid. Sweden will this year require no aid; indeed a considerable quantity of oats and rye already exported, and in spring will export still considerably. Denmark will be able to spare about 250,000 qrs. of wheat.

RUSSIA.—Owing to the high prices ruling during the past year landed proprietors (large and small) have gone on increasing the breadth of soil under grain, and last autumn and this spring the quantity of land sown with cereals was double and treble the quantity sown in comparison to former years, particularly in the following governments principally. In the southern districts in Bessarabia the increase has been chiefly in winter wheat and maize; in Podia (Russian Poland) soft wheat; in the Chernow and Ghirka governments rye; and in the districts of Elisantgrod the increased breadth consisted of barley, oats, and linseed. The seed was got in last autumn under favourable circumstances and wintered well, and the timely fall of snow having afforded them sufficient covering. Seed time in spring also passed off satisfactorily; but later on, up to the end of May, the crops suffered very severely from drought. The government Putlara suffered most from the drought and insects, the so-called corn-worms, thus the crops are in this government not so good as in the others. In the government Kiev the heat was suffocating, being thirty degrees Réaumur in the shade, but rye was in ear, and the rain that fell later refreshed the summer corn. In the neighbourhood of Odessa farmers, despairing of having a good crop, were about cutting the rye, green as it was, for feeding purposes, when early in June rain set in and saved the greater portion of the crops; the rain continued but with few intermissions up to the end of August, nay, even up to harvest, which it greatly retarded, and did more or less damage to the colour of the grain wheat in particular; the quality is tolerably good, and weight excellent, Ghirka wheat weighing in many instances 62½ lbs., and white wheat 61½ lbs. per imperial bushel. The crops along the Sea of Azof, Marianople, Berdiansky, and in the government of Rostoff (on the Don), the crops are by no means as good as last year, the quality is various, also colour, having suffered from rain in July along the Don, particularly government of Rostoff, suffered from drought, mice, and rain, and the crops are even less satisfactory, the quality being poorer than the yield along the Sea of Azof. In Russia Poland (particularly in Podolia) the crops are excellent in every respect; in some few districts hail did harm in July. Central Russia suffered more or less from the corn worms, but on the whole the crops are good. The Baltic Provinces have also been favoured with moderate good crops, notwithstanding the cold, damp, ungenial weather up to July, which caused great fears for their safety. Estland has again been one of the less-favoured governments, plenty of straw but very moderate of corn. In Bessar the hay crop is very poor, rain having damaged it, and also caused more or less sprout in wheat and summer corn.

N.B.—Taking Southern, Eastern, Western, and Central Russia, also Russian Poland, on the whole, and the extensive increase in the breadth sown, the wheat crop may be put down as very satisfactory. Rye a very moderate average. Barley a very full average, light in weight. From the Baltic provinces, little barley will be exported, the demand for homes use being greatly on the increase by the large brewers. Oats also full average, though light weight. Maize and linseed satisfactory. Northern Russia, and even Archangel and Siberia, have had moderate good crops this year, and this is very gratifying after the deficient harvests of the last years. Notwithstanding the good crops, owing to shortness of stocks on the 1st September, we think, Russia will not be able to spare more than last year's, which we then put down, and which turned out to be the quantity we estimated, viz., 1½ million qrs. wheat, and even not so much as that, if prices don't improve.

AUSTRIA AND HER PROVINCES: GALLICIAN, BOHEMIAN, MORAVIAN, AND HUNGARIAN DISTRICTS.—**PROVINCES OF UPPER AUSTRIA.**—Wheat and rye a better crop than barley and oats; on the whole, the cereal crops are about two-thirds of an average. **LOWER AUSTRIA:** Wheat, rye, and barley, not so satisfactory in quantity as oats, which are a very excellent crop, yet, the yield of said cereals are a good average yield, but in quality not so good as last year. **DALMATIA:** Wheat, barley, and oats, a moderate crop, which suffered from ungenial weather in May, and drought in early June, and later on hail. **GALICIA:** In the sown the yield is best; in general wheat suffered somewhat from storms in quantity, but the quality is good; the same may be said of barley; oats in quantity and quality good; buckwheat excellent in every respect; maize good. Peas, in quantity, poor yield, but quality good. Lentils, middling quantity and quality. Potatoes and turnips tolerably good; suffered from excessive rain end of August and early in September. **BOHEMIA:** Wheat, a good crop. Rye suffered from frost at night times in May, but, on the whole, not to any great extent, and the crop is pretty fair. Barley and oats, a moderate average. Hay and clover, not over good. Rapeseed, a failure. Potatoes and turnips, satisfactory. **MORAVIA:** Crops suffered more or less from night frosts in May, and in many sandy districts a large breadth of land had to be ploughed up; maize suffered most; the other cereals turned out proportionately much better in every respect. On the whole, the harvest is a moderate average. **HUNGARY:** In the early part of the year, cereals promised well, though here and there some patches of wheat, which had suffered from dry frost without snow; the said patches were ploughed up and sown with spring corn. Had all gone on well, as the favourable appearance of the crops in spring led one to expect, the harvest would have been equal to that of 1867, or near thereto; the yield, as it is, very obsequered, in some districts good, in some middling, and in others very poor, so much so, that they had to be mowed down for cattle feeding. Great heat in May (29 deg. Réaumur) causing drought; then hail and cold weather in June; this particularly the case in the Temeswar districts, where the crops are the worst. Autumn sown corn in Hungary suffers most; spring corn sown somewhat better. Bulk of straw considerably less, and yield of corn very much smaller the last year. Locusts, end of July and early in August, did also great damage to the crops. In the Banat districts, crops very deficient in quantity, but quality, condition, colour, and weight good; the same may be said of the yield in the Theiss, which is one of the most fruitful districts. On the whole, the crop of wheat is estimated at one-third to one-half of last year in point of quantity; in other respects, excellent, though here and there much is prevalent.

N.B.—Taking Austria and her provinces in general, Low and Upper Austria two-thirds to three-quarters of an average Dalmatia nearly an average. Galicia very good average, as no doubt would have been able to export largely (via Trieste in particular), as the following four Railway Companies, namely, the Lemberg, Csernowitz, the Carl Ludwig, and Northern and Southern Railways, have combined to reduce the rate of freight considerably on grain from Galicia, it is not been that owing to the failures last year in the crop vast deal of the present crop would be absorbed. Bohemia yield good, which is very satisfactory, that province have had a very poor yield last year. Moravia, a moderate average. Hungary, 30 to 50 per cent. under an average exports will be trifling, as all will be required for own consumption and to keep the mills going, although they are now working one-fourth time. There are parties who maintain that, in spite of the deficient crop, Hungary will export freely, giving the following as their reasons for thinking

namely: "In good years, Hungaria produces 60 to 70 million metens (12 to 15 million quarters) of all kinds of grain, of which 40 goes for home use, leaving 20 to 30 million metens (4 to 6 million quarters) for export, and that the deficiency in this year's yield is more than covered by the stocks of old grain held in store." This may be all very correct, but the gents have forgotten to take the quantity of grain required for seed into consideration; and if the official statements of the Hungarian government may be relied upon, the following is the calculation, founded upon last year's good harvest:—44,038,909 metens wheat; 24,636,100 do. rye; and 3,809,500 do. mixed corn, spring wheat, &c.; total, 77,188,000 metens; from which deduct for seed and food for 9,890,400 people, leaves 12,644,600 metens, or about 2,900,000 quarters; last year the crop was a good one, and nearly one-third to one-half larger than the present. Last year we put down the probable exports of Austria and her provinces, of wheat and flour as equal to 14 million quarters; this year, we think, the half, say three-fourth million quarters of wheat and flour, satisfy the latter.

TURKEY AND DANUBIAN DISTRICTS.—**MOLDAVIA, WALLACHIA, TURKEY.**—Same breadth of land sown as last year, but not under favourable circumstances, as it rained heavily during the time, and even continued to fall copiously some time after the seed had been got in, which proved injurious to the crop. The continued drought which followed the rain prevented the grain from germinating; thus, the corn weighs light, but is point of colour and appearance exceeds last year's. Quantity, about half to two-thirds of last year. In the province Diana (that is, Caralla, Port Lago, Kiramati, &c.), the crops are so bad that they won't suffice for home wants, except maize, which is a tolerably fair crop. The province Vola is one of the most favoured, but even there the weight of the wheat and barley is light. **Danubian Districts:** Last autumn (1868) was very unfavourable for getting the seed into the soil, it being too dry, which is a great evil in the Danubian districts, and the seed could only be got late into the ground, but as the months of December and January were very mild, in fact, more like spring than winter months, and had snow only fallen, autumn corn would have promised plenty, but instead of this, dry cold weather, accompanied by biting northern winds, set in, which nearly destroyed the whole of the said seed. The cold, in fact, the winter, did not last long, and the Danube was only closed by ice seventeen days; the spring as customary was damp (which is greatly in favour of spring work), so that the greater part of the soil sown in autumn was ploughed up and sown afresh, and even a greater breadth of soil than usual was sown with grain, and up to the beginning of May everything promised favourably. More land than usual was sown with wheat in particular, owing to the higher prices paid in the last year in proportion to other grain; less maize and barley, but more rye than usually sown. The summer set in dry and hot, particularly in June, and very little rain fell in the Central Wallachia, in fact in some districts thereof, the drought totally destroyed the wheat, barley, and rye. In Moldavia the crops were plentiful and good; in Wallachia Minor, also, good in quantity, but less satisfactory in quality, and in those districts in which too great haste had been made in housing the crops (rain having set in during harvest time), wheat was gathered damp, which spoiled its condition and weight, which is, therefore, very various, never known to be so much diversity as this season, there being wheat of 60 to 62 lbs., and as light as 53 to 54 lbs. Rye is on the average good, also in weight good. Barley, more bad than good. Maize, quality excellent, but quantity far behind expectation. In Wallachia Minor a great quantity of rapeseed cultivated, but nearly all is damp, and, like wheat, cannot well be shipped in sailing vessels; otherwise, the quantity and quality is pretty middling.

N.B.—Taking the Turkey and the Danubian Principalities on the whole, and notwithstanding the extra breadth of land sown with wheat in the latter, we do not think they will be able to export very much more than last year (which amounted to about half-a-million qrs.) we will say at the outside, and to round numbers, 700,000 qrs.

SPAIN AND MEDITERRANEAN DISTRICTS.—**SPAIN:** Crops, large bulk of straw, but of corn very deficient. The Northern provinces, which are the chief and most extensively cultivated part of the country, have been most favoured; but in the Southern the yield is very inferior, having suffered from drought. **Portugal:** Crops were less favourable than in Spain. **Italy:** Crops suffered from great heat and drought in May and June, the excessive heat forcing too premature ripening; locusts did also, in some districts, harm to the crops;

particularly oats suffered. The Central districts have had the worst crops, being 30 to 40 per cent. below an average: the Northern, and then the Southern districts, have fared best. **ALGERIA:** Large breadth of land sown with cereals; crops suffered somewhat in April from continued rain, also from hail; this latter did to barley, particularly in the Tunis districts, a deal of damage. In May a swarm of locusts did a sight of harm; the Southern districts suffered most. Quality of the grain in general is better than last year.

N.B.—Spain, and also Portugal.—Though the crops are better than last year, considerably so, said countries will require, this campaign, extensive foreign aid again. Stocks at harvest time, in Portugal, not being one-third of what was held last year. Italy stocks were more extensive, but the yield is very short, say about 6 to 7 per cent., and this country will also require aid. **Algeria:** In spite of the large breadth of land sown with cereals, the crops are deficient, and Algeria will again require more or less aid from abroad, even though the population of the country has decreased. Taking the Mediterranean ports in general they will require aid from abroad, to at least half what they did last campaign. Many well-informed parties think they will require even more than last campaign, and, therefore, will again be competitors for the surplus of the exporting countries with Great Britain and Ireland, Belgium and Holland.

EGYPT.—Less land planted with beans; yield, per acre, and quality good; but the quantity, owing to the less breadth of land sown, is 20 per cent. less than last year. Barley, about an average. Wheat crop deficient in quantity and quality.

N.B.—A very considerable quantity of land has, this year, not been cultivated, the Nile not having risen to the requisite level, and thus the soil could produce nothing. Egypt will, this campaign, have little cereal produce, especially beans and lentils, to spare for export. We cannot put the probable export at more than 250,000 qrs. wheat.

EAST INDIA.—Crops have suffered very severely from terrible swarms of locusts, particularly in the west province; the havoc done, it is stated, is very great, threatening famine. Rice had risen 25 per cent.

AMERICA.—Extra breadth of land sown with cereals in general, but less winter and more spring wheat. The winter being an open one, the plants suffered no harm; the spring was cold and backward, snow being on the ground in April, therefore spring sowing was late; but the weather in May, June, and July being tolerably favourable, the young wheat, rye, and barley plants promised well, but towards the end of the latter month drought set in very severely, which did sad damage. In the Southern and Eastern States the heat was very overpowering, and the said States suffered most from drought; on the other hand, the Western States suffered more or less from heavy rain, particularly during harvest time, which did harm to the condition and quality, sprout being prevalent here and there. The Central, Northern, North-Western, and North-Eastern States were most favoured, and on the whole the yield is tolerably fair; the winter wheat per acre yielding best, and the quantity of spring wheat is a full average (though not so large as expected), owing to the extra breadth sown; quality of both sorts satisfactory. Oats more sown; crops satisfactory in quantity and quality, though not equal to 1868. Barley, less breadth of land sown, and on that account the yield is under average. Maize is a very bad crop in all sections of the States, having suffered in every stage of its growth from abnormal weather, and therefore must be put down at 30 to 40 per cent. below average. Rye and potatoes moderate crops, particularly the latter. **CANADA:** Crops suffered from storms in spring; wheat not a good crop, but barley is a very full yield. **AUSTRALIA:** The combined heat and drought did a sight of harm, therefore the yield is not by far so productive as last year. At one time the crops promised abundance, and it was expected Australia would be able to export about half a million quarters of grain, but later on the tables were turned. **CALIFORNIA:** More land sown with grain, particularly more barley, the cultivation of this article being yearly on the increase. The crops are this year not equal in any respect to those of last year; the cold and damp weather in July protracted the harvest two to three weeks, and rust is prevalent. **CHILI:** Crops about an average both of wheat and barley.

N.B.—Taking the extra breadth of land and the enormous deficiency of the maize crop into consideration, we think the exporting capabilities of America may be put down at 15 per

cent. more, California 15 per cent. less than last year; and we think we are not far wrong in estimating the probable exports from said countries, including Chili, at 3 million qrs. wheat and flour; last year, we put them down at 2½ million quarters wheat and flour, which appears to have been pretty near (rather over than under) the mark.

SEED TIME.

Seed time this fall has, in the United Kingdom of Great Britain and Ireland, also in France, been good; in Belgium and Holland tolerably so; but in Germany only variable, in some districts good in others bad; for instance, the Königsberg and Holstein grain has been sown but under very moderate circumstances; and in Austria, particularly the province of Hungaria, under very unfavourable circumstances, owing to excessive and continual rain during the seed time, and which flooded the Danube and Theiss, and also the Dran and Sava, doing sad havoc; thus the prospects for the coming crops are not near so favourable generally speaking, as they were last year at this time.

PRICES.

KÖNIGSBERG, 22nd December.—Weather winterly, and the navigation from here to Pillau may be considered closed for sailing vessels. Supplies are very moderate, we note as follows: Wheat, fine, 60 to 61lbs., high mixed, 42s.; fine, 60lbs., mixed, 41s.; fine, 60lbs., red, 39s. per 480lbs. free on board. Barley, 59 to 53lbs., large, 25s.; 49lbs., small, 24s. per 448lbs. free on board. Rye, 54 to 59lbs., 28s. to 30s. per 480lbs. free on board. Peas, fine white boiling, 33s.; good white dry feeding, 31s., per spring the latter 29s. to 30s. per 520lbs. free on board. Oats, 58lbs., 14s. to 15s. per 320lbs. free on board. Tares, 28s. per 520lbs. free on board.

DANTZIC, 22nd December.—Weather winterly and stormy, and except for steamers, navigation interrupted by floating ice, but from Fairwater we can ship. Supplies moderate, demand more active at the reduced prices, which we note as follows: Old wheat, fine, 62lbs., high mixed, 45s.; fair, 60lbs., mixed, 42s. 6d.; new wheat, fine, 60 to 61lbs., high mixed, 42s. 6d.; fine, 60lbs., white mixed, 41s. 6d.; fine, 59lbs., mixed, 40s. 6d.; 57 to 58lbs., mixed, 39s. 6d. per 480lbs. free on board. Barley, 52 to 53lbs., large, 23s.; 48 to 49lbs., small, 22s. 6d. per 432lbs. free on board. Rye, 54 to 58lbs., 26s. to 29s.; 56lbs., per spring, 29s. 6d. per 480lbs. free on board. Peas, fine white boiling, 30s.; good white dry feeders, 29s.; per spring, the latter 29s. per 520lbs. free on board.

STETTIN, 23rd December.—Navigation still free for steamers. Supplies moderate, trade steady, good demand for spring. Wheat, new, 60 to 61lbs., good Uckermarks, Marks, and Pomeranian, 39s. to 39s. 6d.; per spring, 41s. to 41s. 6d.; 69 to 63lbs., fine selected ditto, 40s. to 40s. 6d.; per spring, 42s. to 42s. 6d.; new, 60 to 61lbs., mixed and high mixed, 38s. to 40s.; old, 63 to 64lbs., Uckermarks, Marks, and Pomeranian, 42s. 6d. to 43s. per 504lbs. free on board. Barley, new, 52 to 53lbs., Oderbruch, 27s. 6d. to 28s.; per spring, 28s. to 28s. 6d.; new, 53lbs., ditto, dressed, 28s. to 28s. 6d. per 448lbs. free on board. Oats, 35 to 36lbs., good average Pomeranian, 17s. 6d. to 18s.; per spring, 18s. per 320lbs., free on board. Peas, 64 to 66lbs., feeding 30s. to 30s. 6d.; 64 to 66lbs. boiling, 31s. to 31s. 6d.; per spring the former 31s. 6d., the latter 32s. 6d. per 520lbs. free on board.

ANCLAM, WOLGAST, GRIEFSWALD, DEMMIN, AND STRALSUND, 23rd December.—Supplies, owing to the stormy wet weather, moderate, demand more lively, several orders from the United Kingdom, Belgium, France, and Holland, for spring. For immediate shipment nothing doing, except that a large 2,500 qrs. steamer cargo wheat, being got off from Stralsund, which had been purchased some time ago. Prices are as follows: Wheat, 41s. per 504lbs.; barley, 23s. per 416lbs.; oats, 19s. per 320lbs., all free on board.

ROEROCK, 31st December.—Navigation still free. We may here remind our friends that even should the river from the town to Warnowmünde (the mouth of our river) be frozen over, we can ship overland in waggons at an extra expense of about 9d. per qr., consequently so long as the Sound, or rather Copenhagen and Elsinore roads, keep open, we can ship; *ergo*, our port is the latest closed in winter and the first to open in

spring, which is often of great value to parties who may wish to have their shipments off ere the gross of those from the Upper Baltic, &c., arrives. Supplies liberal, but will fall off, now that the farmers have raised the needful to the Christmas accounts. Our local speculators have been, and are still, buying very freely to hold over till late next summer, they considering present rates as a safe investment. Nothing shipping except one cargo of 800 qrs. per sailing vessel, and 2,500 qrs. wheat per a Flensburg steamer, which has been some months here on our slipway repairing. Some sales, via Hamburg, per steamer, have been made, and are making to Belgium and France. There has also been a good demand from the United Kingdom, Belgium, and France, per spring, but few sales, as our people all point to more money, and stocks are light in the extreme. We note our 61 to 62lbs. wheat 42s. free on board per 504lbs. for immediate or per spring shipment.

WISMAR, 31st December.—Prices about as above; possibly a trifle less might be taken.

HAMBURG, 29th December.—The demand for wheat is but moderate. Wheat, Holstein, 59 to 60lbs., 40s. to 41s.; 60½ to 61lbs., 42s.; Saale, Marks, and Brunswick, 60 to 60½lbs., 41s. to 42s.; 60½ to 61½lbs. Mecklenburgh, 42s. to 43s. per 480lbs. free on board. Barley, Saale, 51lbs.; 35s. 6d. to 36s.; chevalier Saale, 52½ to 53lbs., 37s. 6d. to 40s. per 448lbs. free on board. Good Elbe oats, 20s. 9d. per 320lbs. free on board. Dry fresh Elbe beans, 35s. 6d. per 504lbs. free on board.

FATTENING FARROW COWS.—This is often attended with a great and unnecessary expense of feed, simply because the proprietor does not understand what kind of management such animals require, in order to fatten well and in the shortest possible period of time. Young farmers—and sometimes old ones also, appear to be in doubt whether a farrow cow will or will not fatten as well while she gives milk, and many very intelligent men have continued to milk a farrow cow until she was almost ready for the butcher, and have flattered themselves that the cow was just as fat as she would have been had she not been milked. But no theory can be more absurd. No cow, or female of any kind of animal, can grow fat or fleshy, while giving milk, one half as fast as if they were not milked. When there is a good flow of milk, little or no fat is secreted. And why? Simply because all the nutriment, in the food which they consume, which would form fat or flesh, goes into the milk pail. Therefore, the sooner we discontinue to milk a farrow cow, when we have concluded to fatten her, the sooner she will be ready for the shambles, and the greater will be the amount of tallow and flesh in her carcass. These suggestions apply more particularly to spring and summer. If a farrow cow is in tolerably good condition in the winter, and the calculation is to make beef of her the next summer, or the next autumn, she may be milked all winter, provided she be well fed. But she should be "dried off" before she is turned to grass. Then by allowing such cows to feed on good grass during the summer, they will make fair beef early in autumn by feeding them with only a few bushels of meal. But if they be milked all summer we may expect less and tough beef, and but little tallow. Let farmers remember that if they gain ten dollars in butter and cheese by milking a farrow cow during the summer, they will have ten dollars worth less of beef and tallow than they would have had if the cow had been "dried off" a few months sooner. Young cows that are not too low in flesh dried off by the first of August will usually make good beef late in the fall. The time to discontinue milking depends very much upon the age and condition of the animal, and the amount of feed the owner has. The best beef is that quickest made and when pumpkins and corn can be fed, we would as soon have a cow milked until the first of September as not. An old raw-boned creature should not be milked at all during the summer, if no feed other than that which the pasture affords is to be given, and the meat should be sold to those who have good teeth and strong stomachs. A cow of this kind is never fit for food unless the flesh and fat is laid on rapidly.—*American Stock Journal*.

A VERY LIBERAL AGREEMENT.

Remember always to cultivate your farm according to the practice of good husbandry. Never in any one year plough up from grass more than so many acres of arable land; and after the first, or at all events after the second corn crop taken from the land so ploughed up from grass, be sure to summer fallow the same, or crop it with potatoes or turnips, properly manured and cultivated. Never take more than two corn crops without a fallow or green crop, well manured and cleaned, intervening. With the first corn or grain crop after such green or root crop, sow down every year with at least ten pounds weight of clover-seed and one bushel of well-cleaned perennial rye-grass seed per acre, and so in proportion for less than an acre, a quantity of land equal to what has been broken up from grass. Bear in mind, further, not to mow any of your grass-lands more than once in any one year, and never more than so many acres of the grass-lands in the same year. Cut yearly before seeding all the weeds growing on the pastures and banks. Apply regularly a sufficient quantity of lime to the farm. Never burn any part of the land without the permission, in writing, of the landlord or his agent. Carry all the weeds, collected while clearing the land, to a place convenient for having them rotted and mixed with lime, and applied to the land in the form of compost. Consume by stock upon the premises all roots, hay, and fodder of grain crops grown thereon. Bestow all the manure or compost, made or brought upon the farm in each year of the tenancy on such fields as may from the course of cropping be most in need of manure. Be sure to pay as liquidated damages £5 for every cart-load, and £10 for every waggon-load of hay, straw, manure, or compost which you sell, or suffer to be removed off the farm. Be sure you do not lop, top, or cut any of the trees or underwood on the farm, but carefully preserve these, and all trees hereafter planted, from all injury by cattle, or sheep, or otherwise. Never destroy any of the game, wild fowl, or rabbits, but use your best endeavours to preserve these, and warn off all poachers and other unqualified persons; for do not forget there is reserved to your landlord the fish and fishponds, and all kinds of game, wild fowl and rabbits, for him and his friends, and any other persons with his permission, to hunt, shoot, and fish. Nevertheless you may cut the hedgerows in the months of November, December, January, February and March (but at no other time), when necessary for the benefit of keeping the fences you have made. Before attempting to improve your farm, be careful to give your landlord or his agent ten days' notice of your intention to do so. If you lime your farm, let this be properly applied in sufficient quantities on well-drained or naturally dry land; and be very careful that the seeds you have sown with the crop next after a green crop have grown well, and that the plants are not injured by depasturing and the treading of stock or otherwise. Never neglect to well and properly stock and manage your farm and premises in an effectual manner; and if you wish to leave home for a month or two, mind and obtain your landlord's permission before starting.

And all this excellent advice is not, although it reads very like it, from the new year's number of *The Farmer's Almanac*; is not from the latest edition of Mr. Mechi's book, nor from Mr. Anybodyelse's Manual for Young Farmers. If anything, such instructions sound somewhat antiquated, and out of date in

these times, although, no doubt, the beginner should try to cultivate his lands on some established principle of good husbandry; get his weeds well rotted in a convenient place, and put the manure on such fields as may be most in need of it. On the other hand, it is not now quite so clear that a man should consume *all* the roots and hay he grows, as that it may not occasionally be convenient to sell off a load or two of straw. Still the lime should be properly applied and his seeds well grown; although one can scarcely see the advantage of his not destroying the rabbits, or of cutting the hedges at any very particular time, rather than when it might best suit him to do so.

Such very minute directions, as we have said, have a somewhat old-fashioned twang about them, after the manner of "now pick green gooseberries and look to your celery beds." But it is not so. The instructions we have quoted, if not from a new year's almanac or the last letter from Tiptree, are taken almost word for word from the most recent of all the Model Agreements that have been published. A document of which, when writing on the subject, the agent for the property proudly says: "I shall be very glad if I have suggested anything that may lead to a more liberal construction of agreements in general, the chief thing wanted in many districts to secure the rapid advancement of agricultural prosperity." So that this is not merely "A Model Agreement"—a thing that has certainly become something of a bye-word amongst us—but better still, a more liberal notion of an agreement. A liberal agreement which does not allow of a tenant destroying the vermin, liming his land, levelling an old bank, putting up a wire-fence, or selling a truss of straw without consulting his landlord or the agent upon any or all such important business! A liberal agreement that dictates to a tenant how he shall dispose of his weeds! A liberal agreement of which, as we may assume, the framer says the publication is permitted with "the belief, that containing as it does some important provisions for the protection of the 'improving tenant,' their discussion, and let me hope, more extended adoption, may materially assist in bringing about some much needed improvement in the rural economy of a large portion of the Principality." The writer is evidently serious, and so proud of his handiwork that he openly offers it not only as an example for the Principality, but for the criticism of others further a-field.

It is thus that the commentary follows in our columns, of this day: "*Liberal* forsooth! then, will Lord Lisburne's agent be good enough to favour your readers with what he calls a *stringent* agreement? So far as the wording of an agreement can do it there seems to be not a single process in agricultural pursuits but what the way, the manner, and the time is dictated to tenant. In the schedule of allowances I find the outgoing tenant is to be paid for his new seed bill, if they have been sown in proper course and have *grown well*. Paul plants, Apollos waters, and God gives the increase, but in this model agreement if that increase, from any cause, is withheld, no matter how well Paul plauted and Apollos watered, no remuneration, not even money actually spent is to be allowed!" Our correspondent is, by his own description, "a plain practical man of business, farming 600 acres of land in Lincolnshire," who a few weeks back sent us an able exposition of the Tenant Right of his own county that has since been

copied into half the papers in England. Further than this, at the last discussion meeting of the Farmers' Club, where a form of agreement was under consideration, Mr. Sewell Bead, though he would not appear inclined to give the Club credit for much in this respect, said, as we quoted him a month or so since, "he did not agree that it should be necessary for the tenant to go to his landlord and consult him about every improvement in the cultivation and management of the farm. If a good system of Tenant-Right, similar to that in Lincolnshire, were established throughout the length and breadth of the land, there would be no necessity for the tenant to go to his landlord and say, 'I want you to drain this field, and to chalk that one;' every man would then farm the land in the best possible manner, feeling satisfied that he or his representatives would some time or other reap the benefit." But here the champion of the liberal agreement at once joins issue. With however good a system of Tenant-Right, he *will* still make it necessary for the farmer to go and consult his landlord upon not merely every improvement but about almost every act of husbandry he engages in in the cultivation of the farm.

It is some two or three years that we called attention to a precious agreement that was propounded in Carmarthenshire, and we have here to speak to the merits of its successor in the Principality. But can nothing be done to advance the agricultural tone in South Wales, where it would seem to be politic to give a servant more liberty in his management of your garden than you are prepared to allow a tenant when farming on his own account? With the hope that the discussion of its "important provisions" may do something for the rural economy of Wales, we have given this liberal agreement in full, although certainly with little thought of its "more extended adoption." An old simile says that the buoys at sea serve rather as objects to avoid than attract.

ANOTHER MODEL AGREEMENT.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—We who are deeply interested would be very much obliged by your notice of the Farm Agreements contained in a copy of the *Welshman* newspaper, sent by this post.

We are, sir, your obedient servants,

A FEW WELSH FARMERS.

SIR,—The subject of farm agreements or leases being one, which, from its great importance, has commanded much attention of late, and as you express a belief that the publication in your columns of a new lease, now being granted to his tenants by the Earl of Lisburne, with a desire to improve their condition, by encouraging them to lay out with greater security, more capital and labour in the management and improvement of their farms, would be of some use to many of your readers who are interested in such matters, I have the pleasure of forwarding a copy for that purpose, and I should at the same time, without at all desiring to intrude my opinions on any one, wish to be permitted to make a few remarks on the subject, principally in order that some of the reasons which induced the adoption of the form of lease now in question, may be more readily understood—and I may premise that the consent to publish the lease is all the more willingly given, from the belief, that containing as it does some important provisions for the protection of the "improving tenant," their discussion, and let me hope, more extended adoption, may materially assist in bringing about some much needed improvement in the rural economy of a large portion of the principality. It will scarcely be disputed that the backward state of agriculture in many districts is owing in a great measure, if not entirely, to the prevalence of yearly agreements, determinable with the usual six months' notice, and void of any

security to the tenant for his outlaid capital and labour; and it cannot I think be matter of wonder that under such a system the majority of tenants are unwilling to lay out more money or expend more labour on their farms than is simply necessary to cultivate them, and that too often in a very indifferent manner; and that fencing, draining, and other improvements, are little thought of. I admit there are exceptions, and that we do sometimes see farms managed in a way to reflect the greatest credit on the tenants; but they are sufficiently rare, and what meets the eye too often is—badly tilled, poor, undrained land, neglected fences, and the long string of attendant evils. And if you ask "Why is this?" "Why don't you improve?" the almost invariable answer is, "Give us some security and we will improve." Will any one deny that the man who lays out his money on the property of another is only reasonable when, before doing so, he asks for some security, either in the shape of time wherein to reimburse himself for his outlay, or, in the event of leaving his farm, a guarantee for the repayment of a fair proportion of the cost of his improvements, the benefit of which he has not had time to reap? I am convinced that the proprietor who fails to encourage his tenants to improve their farms, by refusing to grant them some such security, will eventually be the loser. I know the belief is held by many, that leases for at least nineteen or twenty-one years, are the only cure for the evils I have mentioned; but it is questionable if even leases for that period would in a great many cases be productive of the desired result. No doubt to many it would be all that is necessary to induce them to go on with the improving of their lands heartily and energetically, but on the other hand I fear there are many who have fallen into such confirmed habits from long usage that it is at the least extremely doubtful if even a twenty-one years' lease would rouse them from their apathy—and who would only value a lease as the means of securing them in the possession of their farms, which the proprietors would have the mortification of seeing returned to them at the end of twenty years, in as bad, or even a worse state than at present, notwithstanding the introduction of any number of "restrictive clauses." While then I am of opinion that it will be for the advantage of proprietors to give leases of sufficient length to good and improving tenants, it would I fear be unwise to grant them indiscriminately to all the tenants on most estates, without first having applied some test whereby the "worthy" may be distinguished from the "unworthy," and for such a "test" the lease now published, with the "schedule of allowances," will, I hope, prove useful. To the tenant who is desirous to improve, it will give a reasonable security, while to the unimproving tenant it will not, and is not intended to do much, further than to show the material of which he is made. It may be alleged that it is only a lease for one year, and leaves the tenant liable to removal on the usual notice, but here again it will be found to work in favour of the improving tenant. There are few proprietors so short-sighted as to put away their best tenants, and if they did attempt to do so, it is very seldom either convenient or advisable to put away a man to whom a good round sum must be paid for improvements. To another objection that may be urged—that it provides no preventive for the rent being advanced at any time, while the tenant is raising the value of the land by the expenditure of his own capital and labour, and before he has had sufficient time to recompense himself for such an outlay, again the tenant who has most improved his farm will be most secure; for if it is proposed unduly to raise his rent, the fact that he can put his farm into the proprietor's hands and demand payment for his improvement will in most cases prevent any such undue advantage being taken. On the other hand, no right-thinking tenant, after being allowed sufficient time to repay himself for his outlay, will refuse to pay a fair value for his land. While I therefore anticipate that this lease will, in practice, be as valuable to a good tenant as one for a longer period, it will enable the proprietor to judge pretty correctly to whom it will be advisable to grant a lease for a longer term—a thing he will find advantageous to do, as he will thereby extinguish the liability (a very considerable one) which he has created under the "Schedule of Allowances."

The conditions attached to the schedule will, if properly acted on, effectually prevent any confusion arising in regard to the tenant's claims, each improvement account on which there will be any "allowance," being certified and registered

within three months after completion. On the other hand, the amount of outlay on any single farm, and corresponding liability by the proprietor, can be kept within desirable limits by him or his agent, as their sanction must be given (in writing) to all improvements by the tenant, on which allowances under the schedule are to be made, before they are gone into—and while it is indispensable to the successful working of this system to have a carefully kept register of the improvements executed on each farm, in few cases, as far as my experience goes, will it be found necessary to "apply the drag." The oftener such cases do occur, the more encouraging will it be, and then the propriety of granting longer leases may be readily considered.

I shall be very glad, if in venturing on these few observations on a very important subject, I have suggested anything that may lead to a more liberal construction of agreements in general, the chief thing wanted in many districts to secure the rapid advancement of agricultural prosperity.

Yours faithfully,

ROBERT GARDINER (Lord Lisburne's agent).

Wenall House, Crosswood, Dec. 80, 1869.

THIS INDENTURE, made the _____ day of _____ one thousand eight hundred and _____, between The Right Honourable Ernest Augustus, Earl of Lisburne, of the one part, and _____ in the County of _____ of the other part. Whereas the said Earl is entitled to the possession, or to the receipt of the rent and profits of the farm and hereditaments, with the appurtenances hereinafter described, and intended to be hereby demised, as tenant thereof for his own life; and the said Earl has agreed to demise the said farm and premises to the said _____ in manner hereinafter appearing: Now this indenture witnesseth, that in pursuance of the said agreement, and in consideration of the rent, and lessee's covenants hereinafter reserved and contained, he, the said Earl, doth by these presents made in exercise and execution of the power in this behalf vested in him, and also under and by virtue of an Act passed in the 20th year of the reign of Her Majesty Queen Victoria, to facilitate leases and sales of settled estates, and of all other statutes, powers, authorities, estates, rights, and interests, in anywise enabling him in this behalf—appoint, demise, and lease unto the said _____ (hereinafter called "the said lessee"), all that farm, farmhouse, messuages, outbuildings, yards, gardens, fields, lands, and premises commonly called and known as _____ farm, situate at _____ in the parish of _____ in the County of Cardigan, containing in the whole about _____ (little more or less), the particulars whereof are more fully stated in the first schedule hereto, as the same premises are now, or lately were, in the occupation of _____ together with the actual and reputed rights, members, easements, and appurtenances of the said premises respectively. Except and reserved out of this demise, unto the said Earl and his assigns, all such parts of the said farm on which any timber or underwood is growing, with power at any time to plant trees, and to enclose or make plantations on any part of the said farm. And also with full liberty for the said Earl and his assigns, and his and their foresters, servants, and labourers, at all times to enter upon the said farm, for the purpose of repairing fences, planting, pruning, or other management of the woods, trees, and underwood thereon, and to carry off any of the produce of the same. And also except and reserved unto the said Earl and his assigns, all brick-earth, clay, clay-pits, quarries, mines, minerals, gravel, and sand, in, upon, or under the same farm, with full power for him and them, and his or their agents, lessee's, workmen, and servants, at all times to enter on the said farm for the purpose of making trials for the discovery of minerals, quarries of slates and stone, making ponds or water-courses for the conveyance of water, and doing all things necessary for the effectual working of all minerals, slates, or stones, that may be discovered in, upon, or under the said farm, or any part thereof, and to carry off the same at the convenience or pleasure of the said Earl or his assigns, he or they allowing fair compensation for any damage to the surface, and to the growing crops, thereby occasioned, the amount of such compensation to be mutually agreed on, or ascertained by a single arbitrator, pursuant to the provisions of "The Common Law Procedure Act, 1854," and to be allowed for out of the rent, on the next rent day after the amount thereof shall have been so agreed on, or ascertained as afore-

said. And also except and reserved unto the said Earl and his assigns, the fish and fishponds, and all kinds of game, wild-fowl, and rabbits, with liberty for him and them, and his or their friends, and any other persons with his or their permission, to hunt, shoot, fish, fowl, and sport, in, over, and upon the said demised premises, and to go, pass, and repass into upon, and over the same, for any of such purposes. Nevertheless, with liberty for the said lessee, his executors, administrators and assigns, to cut the hedge-rows in the months of November, December, January, February and March (but at no other time), when necessary for the benefit of or keeping the fences made thereby. To have and to hold the said farm, and all other the premises hereinbefore expressed to be demised, with the appurtenances (except as before excepted) unto the said lessee, his executors, administrators, and assigns, from the day of _____ from year to year, until the said Earl or his assigns, or the said lessee, or his executors, administrators, or assigns, shall determine the said tenancy by a six months' notice to quit, in the usual manner, or until the said tenancy shall be otherwise sooner determined as hereinafter provided: Yielding and paying, therefore, yearly, during the said tenancy, the rent of _____ by equal quarterly payments, on the 25th day of March, the 24th day of June, the 29th day of September, and the 25th day of December in each year, the first of such payments to be made on the _____ day of _____ next, and the last of such payments to be made in advance, twenty days next before the ending and determination of the said tenancy. And the said lessee doth hereby, for himself, his heirs, executors, administrators, and assigns, covenant with the said Earl and his assigns in manner following (that is to say), that he the said lessee, his executors, administrators, or assigns, shall and will do, perform, and observe, all and singular the acts, matters, and things, specified, in the articles or clauses No. 1 to _____ inclusively, hereinafter contained or set forth (that is to say):—

1. Pay the said rent hereinbefore reserved, at the times and in manner aforesaid. And also all existing and future taxes, rates, tithe rent-charge, tithes, and other charges, assessments, and impositions whatsoever on the said demised premises, or the rent thereof, or any part thereof respectively (the landlord's property tax excepted), during the said tenancy.

2. Occupy by the personal occupation of the said lessee and his family, or by his executors, administrators, or assigns, the farmhouse on the said farm. Not to assign, or underlet, or part with, all or any part of the said demised premises (except cottages to his or their own labourers, for tenancies not exceeding six calendar months at a time) without the consent in writing of the said Earl or his assigns.

3. Cart all materials free, for any new buildings that may be erected on the said farm, and keep all the buildings in good and tenable repair (English timber in the rough, and slates, being found by the said Earl or his assigns upon request), and carted by the said lessee, his executors, administrators, or assigns), whitewash the outside and inside of walls as they may require it; once in every third year of the said tenancy to paint, with two coats or more of good oil paint, in a workman-like manner, all doors, windows, and wood and iron work of the houses, buildings, and gates, and all such other things as are now, or hereafter during the said tenancy shall be painted by the said Earl or his assigns (which he and they are at all times to be at liberty to do). Repair all fences, roads, and bridges; keep all gates properly hung and in good repair; clean and preserve all young quickhedges, clear the drains, scour the ditches and watercourses, and prevent stagnant water from remaining on any part of the said farm; leave the whole houses, fences, gates, drains, ditches, and watercourses so well and sufficiently repaired, and in such order and condition as aforesaid, on the determination of the said tenancy; permit the said Earl and his assigns, and his and their agent, at any time to enter on the said farm, to view the state and condition thereof, and to give or leave notice upon the said demised premises, or some part thereof, to or for the said lessee, his executors, administrators, or assigns, of any wants of repair, or other defects; and the said lessee, his executors, administrators, or assigns, shall repair or amend the same respectively, within six weeks after any such notice shall be given or left as aforesaid; and in case of any neglect or default, the said Earl or his assigns may do or cause to be done, whatever is mentioned in any such notice, and reasonably necessary or proper, and recover the amount thereof with expenses, from

the said lessee, his executors, administrators, or assigns, by distress and sale, or by action or otherwise, in like manner as for rent in arrear.

4. Insure and keep insured, during the said tenancy, all the buildings hereby demised to the full value thereof, in the

Insurance Office, or in some other Fire Insurance Office to be mutually agreed on, in the joint names of the said Earl or his assigns, and of the said lessee, his executors, administrators, or assigns; and also produce and show the receipt for the last premium paid for such insurance in every current year, whenever requested so to do by the said Earl or his assigns, or his or their agent. And as often as any of the said building shall be burnt down or damaged by fire, lay out and expend, according to the directions of the said Earl or his assigns, or his or their agent, all and every the sum or sums which shall be recovered or received by the said lessee, his executors, administrators, or assigns, for or in respect of such insurance, and such other monies as may be necessary, in building or repairing such of the said buildings as shall be burnt down or damaged by fire as aforesaid.

5. Cultivate the said farm and lands according to the practice of good husbandry—never in any one year to plough up from grass more than _____ acres of the arable land of the said farm; and after the first, or at all events after the second corn crop taken from the land so ploughed up from grass, to summer fallow the same, or crop it with potatoes, or turnips, properly manured and cultivated. Never to take more than two corn crops, without a fallow or green crop, well manured and cleaned, intervening. With the first corn or grain crop after such green or root crop, to sow down every year with at least ten pounds weight of clover seed, and one bushel of well-cleaned perennial rye-grass seed per acre, and so in proportion for less than an acre, a quantity of land, equal to what has been broken up from grass. In the last year of the tenancy, the said Earl or his assigns, or his or their incoming tenant, shall have the privilege of sowing grass and clover seeds among the corn crops, to any extent he or they may think proper, and the said lessee, his executors, administrators, or assigns, shall at his or their own expense harrow and roll them down, and will not allow the young seeds, after the corn is cut, to be pastured or damaged by cattle, sheep, or otherwise.

6. Not to plough or convert into tillage without the consent, in writing, of the said Earl or his assigns, any of the meadow or permanent grass land. The measure of damages for each breach of this stipulation shall be £20 per acre, and so in proportion for less than an acre, payable by way of additional rent, during the year in which such breach shall occur, and during each subsequent year of the tenancy, by equal quarterly payments, on the quarter days hereinbefore mentioned, the first of such quarterly payments to be made on such of the said quarter days as shall happen next after the said breach.

7. Not to mow any of the grass lands more than once in any one year, and never more than _____ acres of the grass lands in the same year. To cut yearly before seeding all the weeds growing on the pastures and banks. To apply regularly a sufficient quantity of lime to the said farm. Never to burn any part of the land without the permission, in writing, of the said Earl or his assigns, or his or their agent. To carry all the weeds collected while clearing the land, to a place convenient for having them rotted and mixed with lime, and applied to the land in the form of compost. To consume by stock upon the premises, all roots, hay, and fodder of grain crops grown thereon. To bestow all the manure or compost made or brought upon the farm in each year of the tenancy, on such field or fields as may from the course of cropping, be most in need of manure. To pay as liquidated damages, £5 for every cart load, and £10 for every waggon load, of hay, straw, manure, or compost, which the lessee, his executors, administrators, or assigns, shall sell, or suffer to be removed off and from the farm, at any time during the said tenancy.

8. Not to lop, top, or cut, any of the trees or underwood on the said farm, but carefully to preserve the same, and all trees hereafter to be planted, from all injury by cattle, or sheep, or otherwise. Not to destroy any of the game, wild fowl, or rabbits, but to use his and their best endeavours to preserve the same, and to warn off all poachers and other unqualified persons.

9. Pay to the said Earl or his assigns an additional rent or rents, equal to five per cent. per annum upon the amount of

any outlay, which the said Earl or his assigns shall at any time or times during the said tenancy incur, with the consent in writing of the said lessee, his executors, administrators, or assigns, in or about the making or repairing of fences or drains, or any other permanent improvements whatsoever—such additional rent to be paid by equal quarterly instalments, on the usual quarter days hereinbefore mentioned, during the continuance of the said tenancy, the first of such payments to commence and be made on such of the said days as shall happen next after the said outlay shall have been incurred as aforesaid.

10. Pay to Mr. _____ the outgoing tenant of the said farm, the allowance (if any) due to him for lime used on the said farm, during the three last years of his tenancy, ending on the _____ day of _____, and for all rye-grass and clover seeds sown by him on the said farm, in the usual course of husbandry, in the spring of the year one thousand eight hundred and _____ (of which the said lessee, his executors, administrators, or assigns, will have the benefit), the amount to be so paid, to be ascertained in accordance with conditions stated in the second schedule hereto, and the same not to be payable until one week after the amount thereof shall have been so ascertained as aforesaid.

11. Leave on the said demised premises, at the determination of the tenancy, for the said Earl or his assigns, or his or their incoming tenant (if either of them shall elect to take and pay for the same at a spending price, and give six weeks' notice in writing of such election, before the ending of the said tenancy, to the said lessee, his executors, administrators, or assigns, or leave such notice for him or them at the principal farmhouse on the said farm) all hay, straw, and roots, being on the said farm, at a fair valuation, to be made by mutual consent, or by a single arbitrator to be appointed by the parties, or by a judge, pursuant to the provisions of "The Common Law Procedure Act, 1854," the same not to be payable until one week after the amount thereof shall have been so ascertained, by agreement or otherwise, as aforesaid. Also leave on the said demised premises, all unused manure without being paid for the same.

Provided always, and it is hereby agreed, that if the said certain rent hereinbefore reserved, or any part thereof, shall be unpaid for one calendar month next after any of the said days of payment (although no formal demand shall have been made for payment thereof), or if the said lessee, his executors, administrators, or assigns, will not, or shall not, do, perform, and observe, all the acts, matters, and things specified in the articles or clauses numbered respectively 1 to _____ inclusively, as aforesaid, and which are to be by him or them done, performed, or observed, or if he or they shall make default in the performance or observance of any such acts, matters, or things, or shall act contrary thereto, or shall be adjudged bankrupt, or make an assignment of all or any of his property, deed of composition, inspectorship, or other arrangement for the benefit of his creditors, or shall depart or absent himself from the said farm, for more than two calendar months at any time, or shall be unable to cease to well and properly stock and manage, or to carry on the same farm and premises in an effectual and profitable manner, then, and in any of the said cases, it shall be lawful for the said Earl or his assigns, without notice, to re-enter into and upon the demised premises, or any part thereof in the name of the whole, and the same to have again, re-possess, and enjoy, as if his or their former estate, anything herein contained to the contrary notwithstanding.

Provided also, and it is hereby agreed, that in case the said Earl or his assigns shall at any time distrain for rent, or any other payment hereinbefore reserved, and then due, he or they shall be at liberty to sell any hay or straw to be taken under such distress, subject to a condition or stipulation that the same shall be consumed upon the said farm, or some part thereof (instead of selling in the usual manner for the best price), and the purchaser or purchasers of any such hay or straw shall thereon be allowed and entitled, and is and are hereby authorised from time to time, during a reasonable period in that behalf, to bring and leave stock on the said farm, or such part thereof as aforesaid, for the purpose of and consuming thereon such hay and straw, without being a trespasser, or being liable to pay any compensation for the same,—nevertheless, the said Earl or his assigns, may distrain and sell in the usual manner, if he or they shall think fit,

And the said Earl doth hereby for himself, his heirs, executors, administrators, and assigns, covenant with the said lessee, his executors, administrators, and assigns, that he, the said lessee, his executors, administrators, and assigns, paying the rent hereinbefore required, and performing and observing all the covenants, articles, matters, and things, by him or them to be done, performed, or observed as aforesaid, shall and may hold the said demised premises during the said term and tenancy, without any interruption or disturbance from or by the said Earl or his assigns, or any other person or persons lawfully claiming by, from, or under him, them, or any of them. And that he, the said Earl, or his assigns, will, on the determination of the said tenancy (provided all arrears of rent to the time of quitting shall have been paid, and possession of the said demised premises given up to him or them, except such parts thereof (if any) as may be holden over by the custom of the country, or by virtue of any stipulation clause or article contained in these presents, and provided all conditions precedent mentioned in the second schedule hereunder written, shall have been duly performed by the said lessee, his executors, administrators, or assigns, but not otherwise), pay or allow, or cause to be paid or allowed by his or their incoming tenant, to the said lessee, his executors, administrators, or assigns, such allowances as are mentioned in the second schedule hereto, less the amount of all damages and sums then payable by the said lessee, his executors, administrators or assigns, to the said Earl or his assigns, for dilapidations, non-repairs of buildings, fences, gates, and drains, or other breaches of any of the covenants, articles, or stipulations hereinbefore contained, such amount to be mutually agreed on, or to be ascertained and determined by a single arbitrator, to be appointed by both parties, or by a judge, pursuant to the provisions of "The Common Law Procedure Act, 1854," before any of such allowances as aforesaid shall be made or paid, and the costs of, and incident to, any such reference and award, to be in the discretion of the said arbitrator, who shall direct by whom, and to whom, the same shall be paid, and shall in other respects have all the usual powers of an arbitrator, and whose award and decision shall be final.

And further, that the said Earl or his assigns will, on the determination of the said tenancy, provided all arrears of rent to the time of quitting shall have been paid, and possession of the said demised premises delivered up to him or them (but not otherwise), allow to the said lessee, his executors, administrators, or assigns, the use of the barns for housing and thrashing the corn crop of the last year, until Lady-day then next, on the condition of a supply of straw being thrashed by him or them, at his or their expense, for the foddering of cattle of the incoming tenant of the said Earl or his assigns, as the same may be required. Provided always, and it is hereby agreed and declared, that neither the heirs, executors, or administrators of the said Earl (but only his assigns) shall be liable for any breach of any of the above covenants, happening after the death of the said Earl. And it is hereby agreed and declared that whenever the "assigns" of the said Earl are hereinbefore mentioned, such word "assigns," shall be construed and deemed and taken to include the person or persons for the time being entitled to the reversion of the said demised premises, immediately expectant on the determination of the said term or tenancy hereby created, unless there be something in the subject or context repugnant to such construction.

And, lastly, it is hereby agreed that the said lessee shall bear and pay all the costs and expenses of and incident to these presents, and of the counterpart or duplicate.

In witness whereof, the said parties to these presents have hereunto set their hands and seals, on the day and year first above written.

Signed, sealed, and delivered }

SCHEDULE OF ALLOWANCES.

The second schedule referred to in the preceding indenture. Allowances to be made for improvements, subject to the conditions undermentioned. No. 1 in each paragraph refers to the description of improvement, No. 2 to the conditions precedent, and No. 3 to the amount of compensation or allowance for the improvement effected. 1. Under-draining done by tenant at his own cost. 2. Provided the drains are cut not less than three feet deep, at regular distances, and are pro-

perly laid and filled, to the satisfaction of the landlord's agent, and are certified by him to be in perfect working order on determination of tenancy. 3. The whole expense of those made in the two last years of tenancy, five-sixths of cost of those made in the third year before quitting, decreasing one-sixth for each crop grown on the land on which drains have been previously made.

1. Draining, the tenant filling only. 2. Similar proviso. 3. Cost of labour in filling drains, made during the three last years of tenancy, at the rate of per perch.

1. Banks and live fences made at tenant's expense. 2. Provided the banks are well formed, and the hedges well cleaned and preserved, and both in good repair at quitting, and so certified by landlord's agent. 3. The whole cost of those made in the two last years of tenancy, four-fifths of those made in the third year before quitting, decreasing one-fifth each year for those made in the three preceding years.

1. Banks and hedges where landlord pays half the cost. 2. Similar proviso. 3. The tenant's cost for those made during the three last years of tenancy, two-thirds of those in fourth, and one-third of those in fifth year before quitting.

1. Levelling old banks. 2. Provided same is done to the satisfaction of landlord's agent, and so certified. 3. Cost of labour at the rate of per perch for those done during two last years of tenancy.

1. Wire fences; the lessor or his assigns providing wood. 2. Provided same are properly erected and in good repair at quitting, and so certified by landlord's agent. 3. Cost of wire for those erected during last three years of tenancy, two-thirds of those in fourth, and one-third of those in fifth year before quitting.

1. Liming. 2. If properly applied in sufficient quantities, on well drained or naturally dry land, and vouched by properly discharged accounts. 3. Three-fourths of cost (of lime only, as at railway station) of that used in last year of tenancy, decreasing one-fourth each year for the two terms preceding.

1. Ryegrass and clover seeds sown in the spring previous to quitting. 2. Provided the seeds have been sown with crop next after green crop, and have grown well, and the plants have not been injured by depasturing and treading of stock or otherwise. 3. The whole expense of purchase as shown by accounts from a respectable seed merchant.

N.B.—In this schedule the word "tenant" means the said lessee, his executors, administrators, or assigns; and the word "landlord" means the said Earl or his assigns.

Such allowances respectively to be subject also to the following conditions precedent, viz.: That the said lessee, his executors, administrators, or assigns, shall deliver to the said Earl, or his assigns, or to his or their agent, ten days' notice in writing of his or their desire or intention to make any such improvements as those mentioned respectively, 1, 2, 3, 4, 5, 6, in the said second schedule: and that the said lessee, his executors, administrators, or assigns, obtain the written authority of the said Earl or his assigns, or of his or their agent, for such improvements respectively, previously to their being made, and provided that within three calendar months next after each improvement mentioned in the said second schedule shall have been made and finished, the said lessee, his executors, administrators, or assigns shall present an account, in writing, of the whole cost of such improvement, and the same shall be certified by the agent of the said Earl, or of his assigns, as correct (either as originally made out, or as corrected and allowed by the said agent). And to prevent mistakes and disputes, such agent shall enter in a book, to be kept for that purpose, a true copy of each account so allowed and certified; and no such allowance as above mentioned shall be made or paid in respect of any matter or thing whatsoever not entered in the said book, and so certified as aforesaid, anything hereinbefore contained to the contrary notwithstanding.

LINCOLNSHIRE TENANT-RIGHT AND THE WELSH LIBERAL AGREEMENT.

TO THE EDITOR OF THE MARK LANE EXPRESS.

SIR,—It is to be presumed from Lord Lisburne's model agreement that Welsh farmers know nothing of their business, and that the Noble Lord has determined to

allow no one to farm on his estate who is willing to do so, except in accordance with his own notions and ideas of agricultural matters and management. I have had twenty years' experience in agricultural matters as a tenant-farmer, &c., in one of the best parts of Lincolnshire, and have during that time seen many agreements, and know most of the arrangements and customs in that county, but I never before believed it possible that any man could string together such a mass of rubbish and call it a *liberal* agreement.

Liberal forsooth! then, will Lord Lisburne's agent be good enough to favour your readers with what he calls a *stringent* agreement? So far as the wording of an agreement can do it there seems to be not a single process in agricultural pursuits but what the way, the manner, and the time is dictated to the tenant. In the schedule of allowances I find the outgoing tenant is to be paid for his new seed bill, if they have been sown in proper course and have *grown well*. Paul plants, Apollos waters, and God gives the increase, but in this model agreement if that increase from any cause is withheld, no matter how well Paul planted and Apollos watered, no remuneration, not even money actually spent is to be allowed.

In Lincolnshire, if a farm is at liberty it is no unusual thing for an agent to have as many as 100 applicants, and so well has the *custom of the country* worked that

in almost all agreements allowances are made to outgoing tenants similar to those I forwarded to you a week or two ago, and those allowances as well as claims allowed to an outgoing tenant, by two valuers, are paid by the incoming tenant, the landlord never appearing in the matter. After the agent has let the farm the entry and valuation are as a rule conducted by two valuers, one appointed by each party, and so well is the custom established that it is seldom necessary to call in an umpire. After this is done grow good crops and keep your land clean, then you have very little to fear; but should a tenant be so unfortunate as to have to quit after a short occupancy his loss is reduced to the lowest possible amount by the custom as before stated. Let agents select proper men as tenants, allow them free scope in matters of management and detail, with a liberal Tenant-Right, and no landlord need fear the result; in fact, the landlord is the man who benefits the most by such an arrangement.

Please inform the Editor of the *Irish Farmers' Gazette* that I claim to be nothing more than a plain practical man of business, farming 800 acres of land in Lincolnshire, and knowing many Lincolnshire men who would gladly farm in Ireland under a liberal system of tenant-right, and without claiming *fixity of tenure*, if life and property were respected.

I am, sir, yours, &c.,

LINCOLN.

CALENDAR OF AGRICULTURE.

The ploughing of stubbles for fallows must be finished early in the month, or better done in the last month; and, also the grass leys for Lent crops. A late ploughing in a dry season keeps the furrows too open and without pulverisation. Carry dung from the cattle yards to heaps in the fields to be sown with green crops. Though fresh and unfermented dung is the best manure for use, the distance of the field from the homestead for the carriage of dung at that hurried season of the year, compels the keeping of farmyard dung in a near proximity, until the day comes of the advantage of moveable railways to produce the quick application by annihilating the distance; which is the peculiar prerogative of that most mighty of all the powers yet given to man. The time cannot be far distant when all the carrying work of the farm will be done by that agent.

The turnips must be all removed from the fields, and stored during the month, earlier or later, according to the climate. Feed all live stock regularly and amply, and thrash grains frequently to afford fresh straws. Greens and turnips will be the green food of the month, with oilcakes to finish any forward fattening bullocks. The sheep now lodged on grass lands are maintained on sliced turnips, chaffs and oats, to be fattened and kept in a forward store condition.

Feed bacon hogs as has been directed, with steamed roots and meals, mashed and mixed; and, as the full fattening is near, with one daily meal of dry grains, as beans and oats, to whiten and bind the flesh into firmness. Store pigs have roots now with a portion of steamed food. Litter the yards frequently, to be dry and warm.

Feed poultry with light grains and steamed roots mashed with meals, in troughs under a sheltered shed. Keep the floors clean. Litter the nests with chaffs and short straws. Begin to set hens on eggs for early broods of chickens.

Ewes will begin to drop lambs—a warm shelter is most essential, with juicy food, as when the dam is nourished the progeny will be reared.

During unfavourable weather, the carrying work of the farm will be done, as the removal of dung, delivery of grains, carrying of fuel and timber, and of stones for building and draining.

Flood watered meadows, and lay dung and composts on grass lands during dry weather; bush harrow and roll the surface, and pick off, by hand, the stones and rubbish that would impede the scythe. Spread mole-hills, and tufts of dung or grass lands, and repair fences and gates into a complete condition.

During the whole month, fell timber and cut under-woods, slash hedges, and plant new lines of thorns, plant all kinds of useful forest trees, though a dry season may prevent the planting in dry situations. Cut close by the ground any unthriven trees of former years, as a more vigorous shoot may arise from the stem. Open ditch plantations, and secure the fences against summer grazings. Fill up the vacancies of last year. Set osiers in beds and in rows on low damp grounds. Lay the beds dry by means of open dividing drains, and dig the ground one year before planting. Use the young stems, strong and healthy, with an eye bud at each end.

Dig hop-grounds, and open the hills to receive manures in very strong farmyard dung in ample quantity—rags, brines, composts of lime, and salt—all oliginous substances do well. Dress the roots, and plant in beds the shoots that are cut off to come in for sets.

Spring wheats are sown during this month on last year's fallows that may have missed the season, or on the turnip lands of the stronger quality, from which Swedish turnips have been grown and removed. This crop of wheat is not much used except in the Border counties, where the common Lammis wheat is sown in to the middle of March, when the crop is equal to the autumn sowing, but may be 10 to 14 days later in ripening in some cases.

On dry warm lands, under benign climates, sow early peas, beans, rye, and also oats in the end of the

month. On very light lands a great benefit attends the early sowings, from the moisture of winter remaining in the ground. In dry seasons the advantage is very considerable to early crops, with rollings very liberally applied.

Vetches must be sown as early as possible on lands of good quality, in an allowance of four bushels of seed to an acre, with a small mixture of oats. A thick seeding is essential to procure a close covering of barley for

an early green food, and for the purpose of smothering weeds and retaining the surface moisture. A thin leguminous crop is a most ruinous possession in growing weeds, and exposing the lands to extreme drought. Every attention must be paid to obtain an early crop of vetches, which form a very important part of the green food of the farm. A barley stubble, or a lay of grass, forms a favourable bed for the vetch plant, and always of good quality.

CALENDAR OF GARDENING.

The first month of spring introduces the sowing of seeds for the early crops that produce seeds as the articles of use; and also the planting of the seeds of the stronger plants of roots, tubers, and bulbs. Three kinds of plants come into the use of the kitchen garden—fibrous-rooted, as the legumes; the stronger roots of the many varieties of cabbages, with celery and asparagus; and the bulbs, taps, and tubers of the turnip, beet, and potato. The first class of vegetables, as peas and beans, are sown on lands prepared by the previous cropping with manures, and brought into fertility with a minute pulverization of the soil; the application of fresh dung raises fibres, stems, and leaves, rather than fruit. Legumes are therefore to be sown on rich lands from a previous crop of taps or bulbs. A slight digging or forking of the land is required, from the winter's exposure, by the ridging of the ground. Cabbages of all kinds are strong plants, and permit the use of the fresh dung from the liquid-pit, and without fermentation, and applied in a large quantity. Asparagus, celery, and rhubarb admit the same application, and also potatoes on dry lands that require moisture. Turnips, beet, parsnips, and carrots are best treated on rich lands without fresh dung, especially carrots, to prevent the luxuriance of tops and fibres beyond the roots that are wanted; the earliest plants of roots on lands previously enriched, and afterwards with dung well rotted in a fermented heap, as has been previously described.

On the dry soils of early climates, sow, in the intervals of fine weather that may happen, peas, beans, carrots, parsnips, onions, and beet-root—all on grounds prepared during autumn, and under the favourable circumstances of soil and climate. The weather, though usually inconstant and characterized by cold and piercing showers of snow, hail, and sleet, is on the whole ameliorated, and permits the operation of spades and forks during many fine intervals. In the later climates hardly any seeds may be planted during this month, though with advantage if at all possible, as early crops are generally the best.

The best kinds of peas for early cropping are Dillstone's Early, Carter's First Crop, Sutton's Ringleader, or Veitch's Early; these varieties are nearly all identical, and any one may be selected for use. Beans in the early long-pod variety, carrots in the French-horn kind, parsnips in the Student sort; onions, any true form of the white Spanish; beet in the very early variety of Dewar's.

Asparagus plots should be particularly attended to. There is nothing surprising in the flaming accounts of the enormous size of this vegetable. Give the plant the advantages of adequate means, and the kitchen garden will produce with any regular market gardener. To make a proper bed a degree of preparation is required, which may be somewhat similar to the following description: This is a crop that ought to yield a supply during twenty years; therefore, this much being expected, the foundation must be allowed to be strong and generous in proportion. Not fewer than four double-row beds should be provided for, and, as the rows of plants must be twelve

inches apart, with an allowance of an equal space on each outer side of the rows, the beds will be three yards wide. Besides the beds, there must be an alley between them, and one at both remote ends. Thus the entire space required will be 17 or 18 feet, the length of the rows being arbitrary.

The whole of this ground is to be dug out, trench by trench, three feet deep, with good drainage where required. If the mould be naturally rich and nutritious, it may all be employed. A bad subsoil must be removed and replaced in the bulk, with turfy loam introduced, and with it "a third part," bulk for bulk, of the best half-rotted farm-yard dung should be incorporated. It would not be amiss to add a bushel of bone-dust, or of guano, which comprises much of that substance, with some salt, sulphate of ammonia, and perhaps chalk. The materials being duly blended, and deposited, the beds will be found to stand high above the ground level, and may remain in that form to settle till Lady-day.

A similar preparation will be desirable for sea-kale, artichokes, and rhubarb, all to continue fertile for several years.

These directions for the production of most truly useful vegetables, and for all other purposes, are simple, and to be done by any tolerably expert farm-labourer, without incurring an expense for professional workmanship.

Sow twice or oftener spring spinach, salads, lettuce, and radish, and at the end of the month carrots, onions, leeks, and some early cabbage, the Early York kind; lettuce, the Paris White Cos; radish, the Wood's Early.

Paraley.—Sow a full crop, either in beds or for edgings: it lasts for two years, but annual sowings are best. In the end of the month sow some sweet herbs, as thyme, hyssop, marjoram, and savory; and further, at pleasure, salsafy, borage, lovage, burnet, coriander, and chervil.

Prepare good loamy soils for garlic and shallots.

In later climates, where hardly any crops can be sown during this month, the operations of winter are continued, in digging lands for crops, levelling the rough diggings of waste grounds, in preparing manures, and in using any advance that appears from the approaching season.

FRUIT DEPARTMENT.

Proceed with the pruning of gooseberries and currants, as the buds will be breaking. Retain a good supply of the best-placed young wood of the former, spurring but little. Currants require rigid spurring, to produce fruit in close clusters. Retain about six canes to each raspberry-bush. Cut these back to the bud, just under the part where the cane takes a bend; then collect and tie them neatly at the summits. Mulch over the ground about the plants; but do not dig the ground, though wandering suckers must be removed.

Fruit-trees may be pruned, as before directed; and finish with pears and apple espaliers, and all the spur-bearing fruit-trees.

Plant beds and borders of strawberries on deep, new, and rich grounds, if possible—Keen's for an early prolific crop; the Pines, the Queens, and Elton's for a later supply.

FLOWER GARDEN.

Sow annuals, seeds of the best sorts, in pots, about the end of the month, in a compost of rich light loam or leafy mould, or very old cow-dung. Heat in a frame

and protection under a glass will be useful for the hardier sorts, as convolvulus, sweet-pea, navelwort, Venus's looking-glass, dwarf lychnis, and candytuft. In open grounds worms, snails, and slugs too often destroy the plants as they emerge.

In the most favourable weather spread over flower-beds a fine compost of leaf-soil or cattle-dung, to be pointed in by hand-fork.

THE SEWAGE CULTIVATION AT LODGE FARM, BARKING.

BY THE HON. HENRY W. PETRE.

The following notes are supplementary to a report published in the autumn of last year, in which the experience of sewage as a farm manure during 1868 on Lodge-farm was described. I have now to review the results of a second year's course of experiments in sewage cultivation conducted on the same farm. The Italian rye-grass being of all the sewaged crops upon the farm the largest in extent, though perhaps not the most important product, shall be first dealt with. The whole area cut over this season is about the same as last year, viz., 53 acres, and it is for the most part the same land; the amount of grass cut exceeds 1,800 tons. The quantities are calculated between 1st September, 1868, and 1st September, 1869. The most advantageous time for sowing, so far as a maximum yield of grass in twelve months is concerned, is probably from the middle of August to the middle of September. It is found from experience that the rye-grass plant under sewage, tested by seven or eight cuts consecutively in the course of a year, will not last in full vigour more than twelve months upon the light soil of Lodge-farm. There is, however, a considerable advantage in sowing a certain portion of grass in the spring, as it attains its strength in the early autumn, when the other grass should be ploughed up or is getting weak. Of the 53 acres above mentioned, 12½ acres were sown last September; they have given in five cuttings 478 tons; and in six cuttings, up to 31st August, 541 tons. Another plot, 10½ acres, gave in six cuttings 371 tons 15 cwt. Of the grass grown in the spring one plot a little less than 2 acres has given in three cuttings 45½ tons; and another, nearly 2½ acres, sown at the same time, has given in these cuttings 59 tons. These plots are strong and will cut well up to the winter. The first cutting of grass this year was in February; it has been cut at intervals of from four to six weeks—on some occasions, when a strong demand existed, no doubt before it was quite matured, and on other occasions when it was past its prime. These irregularities in cutting, which affect the gross quantity, are unavoidable in dealing with such a breadth as 50 or 60 acres, partly consumed on a farm and partly sold in an uncertain market.

The sale of grass this season has been large, and at certain times it has not been possible to supply the demand. All doubts as to its value both as horse-fodder and for cattle seem to have disappeared. There has lately been some public discussion as to its value per ton for feeding cows; there was so great a difference in the value claimed as from 8s. to 15s. per ton. During the months of May, June, and July a daily average of 72 barn-gallons (16 pints each) of milk was produced on Lodge Farm from an average number of 52 cows; the daily feeding of these cows was at one period 4 tons of grass alone; occasionally 100lbs. of maize and 12lbs. of oil-cake were added for cows that had lately calved and those in low condition. Taking the milk at the low price of 1s. 4d. per gallon on the farm, the daily receipt would be £4 16s., and allowing 15s. per ton for the grass, the food would cost, including the maize and cake, £8 9s. In putting the price of the milk at 1s. 4d. per gallon, I give its ordinary value on the east rather than the west side of London, where in fact really good milk (on which basis this statement is made) is worth at least 1s. 8d., which price would give £8 for the 72 gallons of milk per day. Stall-fed milch-cows cannot indeed be fed so cheaply upon any other food with an equal yield of milk as upon sewage-grown rye-grass at 15s. per ton with a small ad-

dition of corn or cake. I must also refer to the result this season of feeding lean stock upon it alone. On the 24th April five steers coming three years old were tied up, their respective live-weights being 7½, 7½, 7, 7½, and 6½ cwt.; the first three were as poor and low as animals could be. On the 15th June, that is in seven weeks, their respective weights had reached 8½, 8½, 8, 8, and 9 cwt. During this period they consumed daily per head less than 1½ cwt. of grass.

I will now detail the results of a crop of wheat 4½ acres, grown for the third year on the same land, the second and third crop being grown with the aid of sewage, and the first without manure of any sort. The soil is a poor gravel, anything but a wheat soil. The wheat is of four sorts, viz.: Taunton dean, long straw white, nursery, and ordinary red. The whole was sown early in November with ten bushels of seed; the crop looked bad all the winter, and up to the middle of March, when it was sewaged, and began to improve. It was sewaged again in the end of April, and a portion received a third dressing in May, and by June, though a thin plant, it was strong. The appearance of this crop was much spoilt, and its yield decreased, by the following circumstance. The land had previously been on the flat, and some difficulty was thus found last year in getting the sewage to flow over the whole; therefore, immediately after harvest, it was put into high ridges 36 feet wide by ploughing and some assistance of hand-labour. The effect of thus moving the soil was to bring on many spots dead sub-soil to the surface; and the natural consequence of immediately sowing the land was that the plant failed, and was over the whole very thin. In spite of this disadvantage, the yield has been at the rate per acre as follows: Taunton dean, 3 quarters 5 bushels per acre; long straw white, 4 quarters, 3½ bushels; nursery, 3 quarters 3 bushels; red, 3 quarters 3 bushels. There were 3 loads of straw to the acre. In the same field six acres of Chevalier barley were sown in March; this crop followed white turnips, that were taken off the land before November, having followed a crop of rye. This crop of turnips produced £11 per acre on the ground. The barley crop looked remarkably well from the time it came up until the beginning of July, when the extreme heat hastened it so much as to destroy the prospect of a good crop. The land was ridged up in the same manner as that for the adjoining wheat, but the intermediate crop of turnips and the winter ploughing prevented any failure in the plant. This crop was, with the exception of one ridge, all sewaged in the first week of May; three ridges were sewaged a second time in the end of May, and a third time before the ear appeared. The result in yield per acre is as follows: That grown without sewage, 14 bushels on half an acre; that with two dressings, 4 quarters and 2 bushels per acre; with three dressings, 5 quarters per acre. Two experimental plots of about one acre each, of superior soil, in another field, were sown with barley, one on the 8th April, and one on the 9th May. The one was dressed with sewage in May, and the other in June. That sown in April looked well throughout, and was cut early in August, yielding at the rate of 6 quarters per acre, of good quality; that sown in May never looked so well, and was cut in the end of August. These crops of barley were the first I have known raised with sewage, and I am disposed to think that it could be better grown in succession to another crop that had been well done with sewage, than by the immediate application of that manure. Two acres of winter oats were

sown after mangold. They did not look well during the winter. They were sown in March and April, and were cut in August, yielding 21 quarters of good quality, with a large quantity of straw. The first attempt at growing horse beans with the aid of sewage has been tolerably successful. The beans were sown in April, after wheat, and received three dressings of sewage. The first dressing, however, instead of aiding the crop, very nearly destroyed it. It was put on by mistake when the plant was not more than an inch or so high, and the weather being cold, it so chilled the ground as to check the growth for some time. When, however, the plants recovered, the growth went on rapidly, the bloom setting well at the bottom of the stalks. The crop was harvested in August. Canary seed has again this year been tried with success; it was sown in March, sewage the end of April and middle of May; it looked well throughout, was cut in the end of August, and is calculated at not less than four quarters to the acre. A first experiment was made this season with early peas; $\frac{3}{4}$ acres were sown after oats on a poor piece of land in November, they never did very well, and were so cut up by the frosts in March that it became necessary to re-sow them; the crop was ready by the middle of June, and picking was continued till the 10th July, when in consequence of the fall in the price the remainder was saved for seed. The early pea crop is at all times a precarious one, and the last spring was particularly unfavourable to it.

I will now pass to the root and green crops, commencing with the early carrots. I may remark that this crop failed last year. An acre was sown in March of this year, and was sown in May, June, and July, during the last month solely for the purpose of drawing the roots, as the ground had become so hard as to make it impossible to pull them. The whole was cleared by the middle of August, producing over £38, and the land was sown down again with Lisbon onions, which, judging from the experience of last year, should be off by May next, yielding £25 to £30 per acre. Adjoining this crop is a very fine piece of parsnips, a better crop than that grown last year, which realised £30 per acre on the ground; this crop has been twice sewage. A most satisfactory result has been obtained this year in potatoes; three quarters of an acre were planted in March with Dalmahoy, Regents, and early Oxford; they were sewage in May and in June, with about 900 tons of sewage in all; by the end of July the ground was cleared, and the crop had produced in the Borough and Covent Garden markets more than £25. The land is now planted with broccoli. French beans have been for the first time grown this year, and with much success; rather over half an acre was sown in April, the weather being very unfavourable. They did very badly at first, the crop was three times sewage, and picking commenced in July; by the end of August the piece had realised over £20. Nine acres of sugar beet have this season been sown in April and May, most of which is a very promising crop. The per-centage of saccharine contained in these roots remains to be ascertained, but I may remark that the sewage-grown sugar beet from this farm last year was found to contain more sugar than any other English specimen sent to the mills at Lavenham. A heavy crop of mangold, under sewage cultivation, is now looked upon as a certainty; $\frac{3}{4}$ acres of yellow globe, sown this year in April (after wheat), sewage in May, June, and July, has presented a fine promise from the first, and the crop may be estimated at not less than 40 tons to the acre. An experiment was tried in transplanting three-quarters of an acre on the 12th of June of yellow globe; it drooped very much at first; one application of sewage set it up, and it has all the appearance of a fine crop, but not perhaps equal in weight to the above. This crop was preceded by winter cabbage, grown with sewage. Another experiment was tried adjoining this, of sowing mangold (long red) early in April amongst the winter crop of cabbage (grown with sewage), and of removing the cabbage as the mangold grew; two dressings of sewage were applied to the mangold, which has now the appearance of a heavy crop. It is the custom of the neighbourhood to plant winter cabbage with a heavy dressing of farm or London manure, and in the spring to plant potatoes among the cabbages. In imitation of this plan, potatoes were planted on 110 rods in the spring among the winter cabbage grown with sewage, and the result has been a crop of potatoes producing £10 12s. Last season a piece of swedes was tried, but the crop

failed, evidently from the seed being of a bad sort. This year an acre was sown in May, and although somewhat damaged by the fly, recovered by the aid of two dressings of sewage, but has now again fallen off, and presents a very indifferent appearance.

The cabbage crop during the year has been large and various. A piece, not quite an acre, was planted with red cabbage in November, and although the crop was much injured by the louse, which attacked the cabbages generally very much during the winter and spring, and though the stock was so bad as to render at least one-third of the plants valueless, it nevertheless yielded by the middle of August upwards of £25. This crop was sewage five times, and I observed that the sewage had a strong effect in destroying the louse, and recovering the plant weakened by its attacks. In September last $\frac{3}{4}$ acres of exhausted ryegrass were ploughed up and planted with cabbage, which was cut in the spring and realised £28, one-half of the plot having received two dressings of sewage and the other three dressings, the latter being the most productive. This crop was much injured by the severe weather in March. Part of a field of 11 acres was planted with cabbage in August and September last, a portion with farm manure and part with sewage; the latter were planted six weeks later but yielded a heavier crop, and when both sorts were sent to market together, the sewage-grown always commanded the best price, sometimes as much as one-third more than the others; this was greatly owing to the superior colour.

During the hot weather of July this year a good plant of white turnips was secured on an exhausted ryegrass plot, and there is now a crop that will be cleared before November, worth £10 to £12 per acre. I have again to refer to the difficulty of raising an onion crop with sewage alone. Since August last two crops have been grown. One acre of Lisbon onions, sown in that month, had by the middle of May realised upwards of £28, and $\frac{1}{2}$ acres of white onions, sown early in March, but which did not look well until June, have realised over £67 for the plot. The real difficulty in applying sewage to this crop appears to be to get the young plant sufficiently strong to bear it, and this difficulty is much greater with the spring than with the autumn crop, because the nights in spring are often, as they were this year, so cold that applying the sewage to the land chills the young plant. It unfortunately happened this spring that on two occasions out of the four that the crop was sewage a sharp frost followed at night, and nearly destroyed the crop; however, it recovered, and grew to be worth what I have stated above. The warmth of the land as well as the weather in the early autumn lessens the difficulty in starting an onion crop at that time. The sewage has the effect, in such weather as we have experienced in July and August this year, of keeping the onions green to the tip of the leaves, strongly contrasting with the ordinary crop. The strawberry crop, as compared with that of last year, has been a failure, chiefly owing to the destruction of the first bloom by the frosts. This, of course, had the effect of weakening the plants, and making the fruit both late and small. As this concludes the detailed account of most of the sewage-grown crops, it will be well to say a few words as to the expense of preparing the land for the regular application of sewage. During the last year I have brought into this state about fifty acres of land in various forms of beds from three feet to thirty-six feet wide; this has been done chiefly by the plough, and the average cost of the formation of these beds has not exceeded £2 per acre. It must be remembered that in the case of the wide beds, such as those from twenty-five to thirty-six feet wide, the formation is permanent; in the smaller, such as those from three feet to six feet, which are similar to the "lands" of ordinary cultivation, the formation must be renewed with each crop, though the dressing of the surface, necessary in some cases, is a permanent improvement. As to the question of the best form and size of bed, it is one that admits of so much difference of opinion and consequent discussion, that I do not think it is advisable on this occasion to do more than state that my present experience inclines me to use wide beds for grass, corn, and such crops as grow thick on the ground, and narrow beds for cabbage, mangold, and such as require space between the plants. The natural formation of the land must in all cases in a great measure guide the farmer in this matter. The land on Lodge Farm is exceptionally flat, and consequently in my opinion the most difficult to get into proper formation.

I will now proceed to give some account of that part of the farm which is cultivated in the ordinary way without the use of sewage. As no artificial or other manure is brought on to the farm, this portion is entirely dependent upon the manure made by the stock on the premises. In no case is sewage and ordinary manure applied to the same crop. The corn crops consist of wheat, of which a $5\frac{1}{2}$ acre field of long straw white, after cabbage, had a promising appearance from the first, until laid by a thunderstorm in July. An adjoining field of ten acres of the same wheat, after potatoes, stood up against the storm, is estimated at six quarters per acre, and is a good sample; both these fields were fed off with sheep. Another field of twenty-one acres was sown with nursery and red wheat, in the proportion of nineteen and two acres; this crop was after mangold, and for some time looked unpromising; it improved in the spring, and is now estimated at five and a-half quarters of a good sample to the acre. Twenty acres of early potatoes after wheat, consisting of shaws and regents, were planted in February; by the middle of August the land was cleared, realising over £26 per acre; 10 acres of this land were brought into form for irrigation as the potatoes were dug, and planted with cabbage, which have produced £20 per acre in the ground. Twelve acres of yellow globe mangold present a good appearance, and may be estimated at over 20 tons per acre. For the purpose of forming some opinion of the intrinsic value of sewage in agriculture, it may be well to consider some of the results of its use in growing the crops already referred to. The crop of winter oats of 11 quarters to the acre is at least double what would have been produced from the land without sewage. This result was obtained by the use of 1,000 to 1,300 tons of sewage to the acre. Potatoes, with two dressings of sewage, yielded a better crop than was produced on land in good condition by the application of farm-yard manure, worth, including the expense of carting and spreading, at least £6 10s. per acre. In cabbage crops two or three dressings of sewage, making from 800 to 1,300 tons per acre, will produce in quantity a crop equal to that raised by means of farm or London manure applied at the rate of 25 to 30 two-horse loads to the acre; whilst the effect on the colour and appearance of the plants caused by the sewage has frequently had the effect of increasing the price from 25 to 30 per cent.

During the year 360,000 tons of sewage have been sufficient to render highly productive 180 acres of the Lodge Farm. Of

this quantity 53 acres have been in rye-grass, bearing an average of five crops in that time, absorbing about two-thirds of the whole quantity of sewage, and more than 50 acres have had two crops, thus making 120 acres of land bear 382 acres of crop in the year. The value of the crops in the gross grown with the 360,000 tons of sewage is over £3,200. As a specimen of the rapidity with which crops can follow each other with the aid of sewage, I may instance a field of potatoes which was planted in February with farm manure and dug during June and July. As the land was cleared cabbage was planted, and in spite of the very hot weather the plants were well established. This crop will be cleared by November, in time for wheat, yielding not less than £20 net per acre. A plot of exhausted rye-grass, which had been cut four times since January, was ploughed up in July and sown with white turnips, which will be off the land by November, giving £10 net per acre. It may be said that this succession of crops is attainable without the aid of sewage. No doubt it is under favourable circumstances of weather and with a large supply of manure, but the advantage of the sewage lies in the fact that the more unfavourable the weather for the ordinary mode of cultivation, the more certain the results from the use of sewage. It may not, perhaps, be out of place to refer to the very unusual character of the seasons in the two years during which I have conducted the experiments on Lodge Farm. Last year was characterised by a summer and autumn of unprecedented heat and drought; the year to which these notes apply was remarkable for a winter of extraordinary mildness, which continued till March, when a real winter commenced, extending, with little mitigation, almost till June, and was succeeded by a sudden and excessive heat. The effects of sewage irrigation, observed during these two remarkable seasons, have fully satisfied me that all descriptions of farm and market garden produce may, with ordinary care, be raised with greater certainty and abundance, and with a less cost for labour, than in the ordinary mode. The certainty is increased by the power of applying the manure at the precise time that the crop needs it. The increased abundance is a necessary consequence of this assistance at the right moment. The saving in the cost of labour is manifest when it is remembered that town sewage, applied by gravitation, needs neither horses nor carts, and that several acres a day may be dressed by one man.

AGRICULTURAL REPORT.

NORTH WALES.

Like most parts of the country we have had heavy falls of rain of late, though we have not yet experienced any unusual flood. The characteristic of the weather since winter set in has been its extreme fickleness, scarcely two days together having been alike as regards temperature and atmospheric appearances. The wetness of November and December caused the wheats to be sown generally late, and the coldness of the soil prevented a rapid germination of the seed, so that it remained buried a long time before the blade appeared above ground. The plant looks healthy, and there is no fear of its becoming winter proud. The pastures have carried a fair quantity of keep, and stock of all kinds have done well. Milch cows at all near calving are in good demand, and fetch comparatively high prices. Sheep are generally healthy, though we have seen in some districts a good deal of scab. Fat pigs sell readily at 5½d. per lb. live weight. The great populations of Birmingham, Wolverhampton, and other large Midland towns, are good consumers of our bacon. They appear able to take any quantity we can send them, and weekly great numbers of hogs are despatched to these busy hives of industry. As the price of oats is low, pig feeding will pay this year notwithstanding stores are very high to buy in. Young ones from the sow, about nine or ten weeks old, fetch from 25s. to 30s. a-

piece. It appears that a corresponding rise in these animals is universal throughout England and Wales. We wish our farmers would be a little livelier after harvest, and do something towards cleansing the stables then. It is quite melancholy to see field after field still untouched, with couch and other weeds making all the running. It is no use to mince matters, we want a revolution in our arable farming. The system, if it can be dignified by such a name, is that of fifty years since, and is entirely exhaustive. Over large tracts something like the following is pursued. A five or six years ley is broken up and tilled two years consecutively, sometimes three years, with a white straw crop; potatoes, with a few acres of turnips, which are all carted off with their tops, follow, and then another white straw crop precedes the laying down to grass again. And as no cattle are fattened, and consequently no good manure made except that from a few pigs, and very little (in many instances not any) artificial manure of any kind bought, it is palpable that the soil cannot under such a course of husbandry increase in fertility. We believe there are many thousands of acres that have not been enriched one iota during the past half century; we are not sure they have not been rendered less productive. By degrees, however, we hope that the great impulse which has been given to all agricultural improvements in England and Scotland during the past twenty or thirty years, will have a stimulating effect upon the agriculture of this part of the Principality.—January 17.

AGRICULTURAL INTELLIGENCE, FAIRS, &c.

BAKEWELL FORTNIGHTLY MARKET.—There was a good supply of stock, with moderate inquiry. Beef—Scots 9s. per 14lb., heifers 8s. 6d., cows 8s. to 9s., according to quality. Barren cows from £11 to £15 each, heifers £11 to £15, sturks £7 to £11, yearlings £5 to £6, calving cows £17 to £24, ditto heifers £14 to £17, spring calves £11 to £15, ditto sturks £8 to £11 10s. each. A moderate supply of mutton; best quality 9d. per lb., ewes 8½d., rams 7½d. A good supply of pigs, at rather less money, prices varying from 30s. to 55s., according to size and quality.

BANBURY FORTNIGHTLY FAIR.—There was a good supply of sheep, but there seemed to be little demand, and the prices realized were from 5s. 6d. to 5s. 8d. The cattle were principally stores.

BRIDGNORTH FAIR.—The supply of horned cattle was small, particularly fat stock. The show of horses, pigs, and sheep was not much better. Good cows and calves fetched £13 to £18, good store pigs £2 to £2 10s., waggon horses £16 to £18.

CHURCH STRETTON FAIR.—The supply was below the average, beef realising 7½d. per lb. and mutton 8½d. to 9d. Pigs were sold at high prices.

DUNFERMLINE MONTHLY MARKET.—The attendance of purchasers was large, and there was a brisk and ready sale. Cows and queys brought from £10 to £18, being from 9s. 6d. to 10s. 6d. per Dutch stone; and milk cows brought from £8 to £13. The best sheep brought from 32s. to 45s., being from 8d. to 9d. per lb.; ewes from 13s. to 35s., or from 6d. to 7½d. per lb. A few remained unsold. The best cattle brought from £15 to £25 17s. 5d., being from 10s. to 11s. per Dutch stone. Pigs from £1 10s. to £6 10s., about 6d. per lb.

FORRES MONTHLY MARKET.—Some lots of prime fat, of which there seem still to be a good many in the county of Moray, were brought forward. Sales were somewhat stiff, but not a few lots were disposed of at remunerative rates, and the general average may be quoted at from 65s. to 70s. A lot of fourteen three-year-old crosses sold at £26 5s.; five three-year-old, polled, at £19; a stot and a quey for £65 the pair; four two-year-olds, polled, at £24; a fat cow at £18.

GLOUCESTER FORTNIGHTLY MARKET.—There was an average supply of stock, which sold readily, beef realising 7d. to 7½d., and Mutton 8d. to 9d. per lb. Pigs hardly keep up their late value, 11s. to 11s. 6d. per score being the present price.

GRANTHAM FAT STOCK MARKET.—A small show of beasts, but a good supply of sheep. Good prices were realised, many buyers being present. Beef made 9s. and pork 9s. per stone, mutton 7½d. to 8½d. per lb.

HAILSHAM NEW STOCK MARKET.—Welsh and Scotch runts, Sussex oxen, steers and heifers 5s. to 5s. 4d. Sussex cows 4s. 6d. to 5s. Southdown wether mutton, 6s. to 6s. 4d. Kents wether mutton 5s. to 5s. 8d. Veal 6s. There was a good supply of very good beef in our market to-day, for which trade was brisk, and a good clearance made. Good mutton sold readily at the above quotations, but with the inferior trade was heavy.

HIGHBRIDGE FORTNIGHTLY MARKET was moderately supplied with fat beasts, which met a tolerably ready sale at 12s. 6d. to 13s. per score. Of fat sheep there was a fair supply, and former prices realized—8d. to 8½d. per lb. There was a small number of cows and calves on offer, which changed hands at £14 to £16 each. Pigs in moderate supply, and for quarter-old alips 25s. to 30s. each asked; large store pigs 50s. to 60s.; good sows £5 to £5 10s.; but buyers were scarce, and but little business was done.

KNARESBRO' FAIR.—There was a good attendance of buyers and a plentiful supply of fat stock, at 8s. to 8s. 6d. per stone, part being left unsold. Calving Cows rather lower in price. Pork Pigs 9s. per stone. Fat Calves 7½d. per lb. A good supply of lean stock and a poor show of Horses.

LINCOLN FAT STOCK MARKET.—A small show of sheep but good in quality and a shade lower. The same may be said of beasts, which sold from 8s. 6d. to 9s. per stone.

LINLITHGOW FAIR.—All the stock was fresh. Twelve milch cows sold at prices ranging from £8 to £14, and stots £13 10s.; farrow cows at £8, and milch cows at £13 10s.

Messrs. Kirk and Duncan purchased milch cows at from £14 to £17. Mr. Henry Aitken sold milch cows at from £12 to £16 10s. Calving cows sold at £15.

MELTON FAIR was well attended by both buyers and sellers. The show of horned cattle was considered scarcely so numerous as on some former occasions. Both stores and meat beasts were decidedly lower, and to effect sales a reduction from recent prices had to be submitted to. The pitch of sheep was small. Some useful draught cart-horses were exhibited, and prices were high for good ones.

MORETON GREAT MARKET.—There was but a thin supply of cattle, not equal to demand, sales very brisk. Cows and calves from 12 to 22 guineas each. Fat bullocks 12s. to 12s. 6d. per score. Sheep, fewer penned than is usual, 6½d. to 7d. per lb. Lambs 20s. to 22s. each.

MUR OF ORD MARKET.—The first market for the season was held on Thursday. The chief demand appeared for fat beasts, and also for those in forward condition: in both classes the demand was brisk, and the prices realised were considered very good. The small supply of stock at the market is attributed in some measure to the plentiful supply of the turnip crop, giving sellers to hope that with further feeding by next market the prices will rise yet higher. Several lots of sheep were exposed, the greater part of which were sold at good prices. Beef may be quoted at from 65s. to 70s. per cwt. The following are some of the transactions: Two-year-old Highland heifers, fat, sold at £13 10s.; cross calves from £4 10s. to £6; two-year-old crosses from £10 to £14; and cross cows from £8 to £13. Mr. Adam sold two-year-old crosses at £13. Mr. Alexander Urquhart sold two-year-old cross stots at £11 10s. Mr. Jack sold two-year-old cross heifers at £10. Mr. Fowlie bought cross cows at £9. A milch cow for £6 15s.; cross calves at £5, and a cross cow at £9. Mr. William Anderson bought two-year-old Highland queys at £8 10s., and a two-year-old cross quey at £17.

NOTTINGHAM FAIR.—For animals of good quality there was a steady demand, and prices were about the same as heretofore, but inferior sorts were a very heavy sale, and late rates were difficult to support. Best milch cows made £20 to £23, other sorts £16 to £19, barren cows £12 to £16, heifers £10 to £15, sturks £6 to £7 per head. There was a small show of calves, and the trade was quiet at about former prices, 20s. to 40s. each. In sheep there was scarcely anything doing. Of horses the supply was only middling. Really useful animals, however, met a fair demand, and high prices were in most instances realised. Carriage horses and weight-carrying hunters sold at £65 to £70, the best ranging up to £100; useful horses for agricultural purposes £45 to £50, hacks and cobs £25 to £35, ponies £15 to £18 each.

SLEAFORD FAT STOCK MARKET.—A large supply of sheep, which met with a ready sale at late prices. Fair show beasts, which sold at late rates. Small show of pigs. Mutton from 7½d. to 8½d. per lb., hogs from 35s. to 45s. each; beef from 8s. 9d. to 9s. 6d., pigs from 8s. to 8s. 6d. per stone.

WHITCHURCH FAIR.—There was a good attendance. The show of stock was not so large as at the previous fair, but good considering the time of the year. There was a fair supply of pigs in the pig market, where business was brisk. Some capital cows, heifers, sheep, and pigs were well sold.

WORCESTER FAIR.—There was a very large market, and a great quantity of stock. Beef made 7½d. to 8d.; mutton, 8d. to 9d.; pigs about 11s. per score.

IRISH FAIRS.—NAAS: The demand, except for strippers and springer cows, was dull, as is usual at this season of the year; owing to the dearthness of fodder and scarcity of grass buyers generally wait till the February, which brings them a good way into spring. There was a fair supply of pigs, which, as usual, met a ready sale at the full rates which have been for some time current. In the sheep fair there was a middling attendance, and good mutton went off freely. Three-year-old heifers £13 to £14, two-year-olds £9 10s. to £11 10s., two-year-old bullocks £10 to £11 10s., year-and-half-olds £5 to £6, strippers £9 to £12; milch cows £13 to £18, meeting a brisk demand; fat sheep, 40s. to 60s. each; good hoggets, 32s. to 37s. 6d.; lambs, 21s. to 30s.; store pigs, 55s. to 60s.; bonhams, 25s. to 30s.; bacon pigs about 60s. per cwt.—

BALLTAY: Bacon pigs sold at 52s. 6d. to 57s. per cwt.; and stores at £1 7s. to £3 each. The largest fat pigs I saw was sold at £8 13s. Young pigs were sold at £2 to £2 5s. per pair. There was a fair supply of beef cattle selling at £10

to £35, springers £9 to £16, strippers £9 to £12 each. The demand for farm horses was great, and prices were very good.—**MAGUIRESBRIDGE**: Springers, scarce, changed hands at £18 to £19 each. Fat milkers sold at £17, and a few good animals fetched £20 each; three years old heifers sold easily at £17 to £18 10s. each, two years old at £11 10s. up to £12; year-olds fetched from £5 18s. to £7 10s., top quality. Beeves and three years old bullocks sold at £14 up each; two years old sold from £8 up, and yearlings £3 to £5 8s., which was obtained for some fine specimens. Stirks and strippers were scarce, and sold from £7 10s. to £9 each up. Good cows in calf £11 11s. to £13 10s. The show of cows and springers was not large, nor was beef largely represented. Inferior milch cows, as usual, were numerous, and sold from £7 up. Calves were numerous and sold from 30s. each. Sheep were pretty fairly supplied, but very few animals of top quality were offered at all, and most of the purchases were made by the neighbouring victuallers. Best mutton may be quoted at 6½d. per lb. Fat sheep fetched 38s. to 51s., store hoggets 31s. to 38s. 6d., and lambs 24s. to 36s., according to quality. Best pork fetched 53s. to 54s. 6d. per cwt., stores £2 to £3 10s. each, bonhams 24s. to 30s., and suckers 10s.—**SLANE**: Prime animals were eagerly picked up at an early hour, and principally for home consumption. The highest price per lb. was 7d. to 7½d., sinking off. Victuallers received 9d. to 10d. per lb., which left them a large margin of profit. Second class 50s. to 52s.; and inferior 4s. per cwt. less money. In store cattle little business was transacted, except for well-conditioned bullocks. Inferior bullocks and heifers were at a discount. One lot of three-year-old bullocks fetched £15 10s. The ruling prices, for those fit for export, were £8 10s. to £13 10s. Two and a-half year-old heifers £11 to £13 per head. Springing cattle sold from £11 to £16 each. A few very

inferior ones went at £7 10s. to £9 a-piece. The sheep fair was a busy one. Best wethers £2 15s. to £3 each, or 8d. to 9d. per lb., ewe mutton of best quality 6½d. to 7½d. per lb. The swine fair was well attended; light bacon pigs on the foot went from 58s. to 60s. per 112 lbs. Store pigs from £2 to £3 10s. each; slips 18s. to 24s. each.—**DUNDALK**: Superior beef brought 6½d. to 7d. per lb.; inferior ditto 6½d. to 6d. There was a large supply of store cattle, at for three-year-olds from £10 to £12 each; two-year-olds from £5 10s. to £7 15s. per head. Stirks from £6 10s. to £7 10s. each. Good springers and milch cows were anxiously looked after, but were exceedingly scarce. In one instance as much as £20 was offered for a very fine milch cow, which was refused. Fat wethers brought from £2 2s. 6d. to £2 10s. per head; fat ewes, 38s. to 46s. per do.; superior mutton may be quoted as selling at from 6d. to 7d. per lb. The pig fair was very largely supplied. Bacon rated from about 52s. to 54s. per cwt.; stores, 42s. to 52s. each; bon-nives from 16s. to 25s. for mere suckers. Farm horses, very limited supply, ranged from £17 to £18 10s. each, and a pretty brisk business was done.—**CASTLEBRIDGE**: Prime beef, from 60s. to 65s. per cwt.; middling and inferior, from 43s. to 50s.; three-year-old heifers and bullocks, from £12 to £14 each; two-year-olds, from £7 to £11; yearlings, from £4 10s. to £6 15s.; new milch cows from £14 to £20; springers from £9 10s. to £15; strippers from £3 10s. to £14; fat sheep from 40s. to £3 10s.; stores from 36s. to 48s. each; lambs from 24s. to 36s. each; bacon pigs from 55s. to 56s. per cwt.; store pigs from 46s. to 58s.; bonhams from 20s. to 28s. each.—**ATLONE**: The supply of pigs was much larger than for many years past. Some large pigs brought £8. The average price for fat pigs was £5 10s., or fully 6d. per lb. on their feet; stores and small pigs not in demand.

REVIEW OF THE CORN TRADE DURING THE PAST MONTH.

The beginning of the year, which promised at Christmas to open with more life and better prices, has been disappointing. The sudden break up of frost as January came, brought back the old feeling of the trade in the expectation of further foreign arrivals from the speedy opening of the Baltic. Frost has, however, once more visited us, but there is little belief that it will be severe, or of any continuance, and prices for the month have given way 1s. to 2s. per qr., though receipts in London have been inconsiderable. It is not forgotten that we began the year with a stock of about 2 million qrs. of wheat, of which about 500,000 qrs. were in London, and though money is not tight, and there is no prospect that it will be so, millers of substance with tidy lots of their own prefer looking on to increasing them. But after all, what is two millions quarters but about a month's consumption for the kingdom? As most of this was bought at about present rates, the monetary pressure is not over 4½ million pounds widely spread. We reckon that notwithstanding the present pressure, our wants will be fully six million quarters more up to 31st August, and should foreigners not like present rates or prospects, we may yet get a turn before them. Nothing is, indeed, yet the matter with the growing crop, but it is small and backward, and should an ungenial spring be before us, there is plenty of room for a rise, when speculation might put our granaries comparatively into a state of blockade, as well as raise foreign markets. Odessa has, indeed, about one million quarters, but merchants there, with banker's aid, can very well bear the weight of value but little beyond 1½ million pounds, and by the latest advices they seem to mean it rather than ship at a loss. New York is always more ready for a rise than decline, and though some people lately thought California would turn out wheat

like the sands in quantity, they have lately found a better demand there at firmer rates. And we have always found low prices have so many chances, that we should not be at all surprised to see present rates exceeded by 10s. per qr. before the cereal year has expired. France, too, receiving large imports constantly, has lately noted a moderate rise at Paris and some country places. The following were the recent values of wheat at the places named: white wheat at Paris 49s. 6d., red 46s. 6d., white at Bordeaux 47s., red in Belgium 46s. to 47s., white Zealand at Rotterdam 42s., red qualities at Hambro' 39s. to 40s., at Cologne 39s. 6d., at Stettin 40s. 6d., mixed to high mixed at Dantzic 34s. to 46s., wheat at Romanshorn 43s. to 50s., at Porrentruy 43s. to 47s., the heaviest red at Pesth (Hungary) 39s., low sorts 33s., soft at Odessa 25s. to 31s., white Buhi at Alexandria 35s. 6d., hard at Algiers 40s., red at Vienna 42s. at Naples 43s., Marianopoli at Genoa 38s., No. 3 spring red wheat at New York 33s. 6d. per 480 lbs., No. 2 37s., winter red 39s., Californian white 43s. 6d., white at San Francisco 30s. 6d., spring No. 1 at Milwaukee 24s. 6d.

The first Monday in Mark-lane commenced on a small supply of English wheat, with but moderate arrivals from abroad. The show of fresh samples during the morning being exceedingly limited, factors were able to make sales at the former Monday's rates, but the sales were slow. The inquiry for foreign was quite retail, and though no general decline was noted, the tendency was certainly downwards, and less must have been taken had sales been forced. With but few arrivals off the coast prices were maintained. The very decided change from frosty weather to excessive mildness, coupled with the dull statements from London, occasioned a loss in the country markets of all

that had been gained during the previous week, the improvement then, in some cases, being 1s. and in others 1s. to 2s. per qr. Liverpool also gave way 5d. per cental for the week, or about 2s. per qr. Edinburgh and Glasgow noted sluggish markets for wheat, with the turn in favour of buyers. Ireland was equally dull, and the markets for wheat rather worse.

On the second Monday the returns of English wheat were about the shortest since harvest, but foreign supplies were somewhat increased. The morning's show of samples on the Essex and Kentish stands was very poor, both in quantity and quality. The few lots really fine and dry went off, but not readily, at the previous rates: inferior were neglected. Foreign wheat was generally dull, and Russian, as well as American sorts, gave way fully 1s. per qr. Floating cargoes were a heavy sale at a 1s. decline. Though the temperature this week was lower, and night frosts prevailed, there was no recovery in the tone of the country trade. But little was passing anywhere, and under the idea of foreign ports shortly reopening, prices universally pointed downwards. Alford, Boston, Barton, Birmingham, Ipswich, Hull, Bury St. Edmunds, Market Harborough, St. Ives, Rugby, Rotherham, and Gloucester were all 1s. per qr. down; Barnaley, Melton Mowbray, Wolverhampton, &c. being 1s. to 2s. per qr. lower. Liverpool lost 2d. to 8d. per cental, or 10d. to 1s. 3d. per qr. Edinburgh was dull, and Glasgow down 1s. per qr. Dublin was 8d. to 6d. per brl. cheaper, and Cork remained in calm.

On the third Monday there was a rather better supply of English wheat, though still short; but the foreign arrivals were reduced. Again the show of fresh samples from the near counties was very limited, and from the damp and variable weather mostly in poor condition. This circumstance alone kept the few lots in good order at about the former range; but it was realized with difficulty, and rough lots were quite of uncertain value. The foreign demand remained very slack, and a reduction of 1s. per qr. accepted on all but the finest Baltic and white qualities. With a large fleet off the coast, no progress in sales could be made without accepting a similar decline. The country markets, with broken weather and such dull accounts from London, gave very few signs of animation in business. Most accounts were heavy. Many were down 1s. per qr., viz., Sleaford, Spalding, Market Harborough, Melton Mowbray, Louth, Newark, Alford, Ipswich, Thirsk, Hull, Bury St. Edmunds, Manchester, and Wolverhampton, and a few declined 1s. to 2s., among these were Barton, Rotherham, Sheffield, and Stockton. Edinburgh was 1s. cheaper, and Glasgow very dull, Dublin was 6d. to 1s. per barrel cheaper for Irish wheat, with hardly anything passing in foreign.

The fourth Monday opened on moderate English supplies, with fair arrivals of foreign. The show of samples on the Kentish and Essex stands was limited, and again mostly in poor condition. The few lots of fine white that appeared went off more readily, at the full prices of the preceding Monday, but inferior parcels hung still on hand. The business in foreign continued on a limited scale, and though all fine white high-mixed Danzig and red Baltic qualities maintained their value, there was more difficulty in clearing off fine sorts. Cargoes almost were, however, 6d. dearer for fine wheat. The imports for four weeks into London were 13,124 qrs. English wheat, 58,427 qrs. foreign, against 15,618 qrs. English, and 48,851 qrs. foreign at the same time in 1869. The imports into the Kingdom for four weeks, ending 15th Jan., were 4,482,495 cwt. wheat, 697,018 cwt. flour; against 1,710,850 cwt. wheat, and 397,344 cwt. flour for the same period in 1869. The London averages commenced at 43s. 11d., and closed at 46s. 7d. The general average opened at 43s. 5d., and closed at

44s. 1d. per qr. The London exports for four weeks were 2,260 qrs. wheat.

The flour trade, with good supplies from the country and fair foreign arrivals, has been dull all through the month, with a downward tendency; and to have sold freely on the last market, it would certainly have been necessary to accept fully 6d. per sack less. Barrels too, which have been relatively dear, closed somewhat cheaper, 28s. being about the value of superfine State, and French scarcely 84s per sack. Town qualities have been steady, the top price continuing 43s. per sack. The imports into London for four weeks were 87,930 sacks English, 9,714 sacks and 21,709 barrels foreign, against 75,950 sacks country, 2,113 sacks and 2,809 barrels in 1869.

Though the supplies of Indian corn have been moderate, the low prices of oats and great reduction in beans and peas, have contributed to keep prices at a very moderate range, say to 29s. per barrel for fine heavy yellow, and 80s. for Galatz white. The imports into London for four weeks were 27,514 qrs., against 28,280 qrs. last year.

Though the supply of malting barley, both English and Scotch, has continued on a moderate scale, prices were barely so good, excepting for anything really choice. Such being scarce, commanded a full market value. Secondary and inferior grinding foreign have given way full 1s. per qr., with but a retail inquiry. The supply for London for four weeks in British qualities was 16,812 qrs., and in foreign 37,061 qrs., against 17,823 qrs. British, and 48,740 qrs. foreign in 1869.

The malt trade has ruled extremely dull, brewers still complaining of a very limited consumption of beer, owing to the want of employment of the working population. Prices have therefore given way fully 1s. per qr., and are not to be depended on.

The low prices to which oats have been reduced have almost excluded English growths from the London market, while neither Scotland nor Ireland have sent on any shipments. Foreign arrivals have been irregular, commencing and closing freely, though the intermediate weeks brought but little. Yet, on the third market, with mild weather, and the prospect of further large imports, prices gave way 6d. per qr. On the fourth this was more than recovered, the rise on fresh Swedish being 6d. to 1s. per 38lbs., best quality being worth 19s. 6d. Russian sorts, though unchanged in value, sold more freely, say at 18s. 6d. per 38lbs. from granary. Prices seem too low for any material reduction, and it is plain that farmers of the United Kingdom do not intend to meet present rates, even if they have any stock left. Should there be any falling-off in foreign in consequence of frost, it seems very probable we shall be higher; and it is even doubtful, when the frost is gone, whether Swedish and Baltic export-houses will be induced to make shipments to meet present rates. The imports into London for four weeks were 1,380 qrs. English, 147,582 qrs. foreign; against 2,506 qrs. English, 960 qrs. Scotch, 8,055 qrs. Irish, 117,664 qrs. foreign, for the same period last year.

Beans have almost been constantly receding in value all through the month. It was very singular that farmers, when prices were 6s. to 8s. higher, at the commencement of the season, did not then forward their produce. It has lately come forward freely, and the consequence has been a steady downward course in demand and value, from the low price of oats, grinding barley, and maize. Fair small English new have been selling at 33s. to 39s.; old Egyptian at 34s. to 35s., and other qualities in proportion. The decline on new this month has been fully 8s. per qr., but we think the lowest point has been nearly reached. The London imports in four weeks were 3,083 qrs. English, 3,479 qrs. foreign; against 2,040 qrs. English, 12,598 qrs. foreign last year.

Peas have been in sympathy with beans, the frost not continuing long enough to originate an active inquiry for

boilers; they have receded in value about 8s. also, and old have been left for consumption as horse food, and brought only 83s. per qr., which is about the value also of duns; maples nominally 38s. London imports 2,019 qrs. English, 6,429 qrs. foreign; against 1,246 qrs. English, 766 qrs. foreign in 1869.

From the moderate imports of linseed it has risen 1s. per qr.

A quiet trade has been going on in cloverseed, chiefly in fine red qualities, at quite former rates, France this year not being able to send much of what the London market requires.

Tares have found rather more demand at 85s. for small Hambro.

PLATE V.

SOUTHDOWN WETHERS:

THE PROPERTY OF LORD WALSINGHAM, OF MERTON, THETFORD; AND WINNERS OF THE CHAMPION PLATE OF £50 AS THE BEST PEN OF SHEEP AT THE SMITHFIELD CLUB SHOW, 1870.

"Lord Walsingham never showed sheep of purer Southdown type than he has done this year at Birmingham. The first-prize pen were very pictures of what they should be; so admirably matched, with such nicely-shaded shapely faces, such neat symmetrical frames, and all over of such high breeding and quality. They were not large, certainly; and we were almost sorry to hear that they will go for more size in London. During the last twenty or thirty years, some alloy no doubt has been tried with the Southdown, but this is a mistake; for what we gain in weight we lose in almost every other way. The second-prize Merton pen were not equal to the first, but if there had been a cup for the best entry of any animals in the Hall, the Southdowns would have won it."

It was thus that we wrote of the best sheep at Birmingham; while of the Smithfield Club champions we said:

"The great pride of the show was clearly to be found amongst the Southdowns. Lord Sondes had some very good second-prize shearlings, and Sir W. Throckmorton's third pen were heavier than the first shearlings; but the style and quality of the Mertons were deservedly triumphant, as it is to be hoped we are coming to see that it is not mere weight which marks the excellence of a Southdown. The light-weights from the same famous flock were still prettier, and Mr. Foljambe and Lord Sondes quite deserving of their places, keeping to purity of type as well as to early development; but Mr. Rigden, whose stock would seem to come very capriciously, was in no force, and Sussex, indeed, quite out of

form. No wonder that the judges commended the class of old sheep, for never has there been one so regular and true in form after high feeding from very lambhood. And here the Merton wethers reigned supreme as they deserved, for taking them all in all, for fineness of touch, broad and level shoulders, muscular backs and rumps, and 'legs of mutton,' they were certainly pictures to look on, and the £50 award spoke for itself."

These sheep were 32 months and 2 weeks old, and the weight of the pen 6 cwt. 1 qr. 25lb. The Judges at the Smithfield Club Show were Messrs. H. Hart, Beddingham, Sussex; H. Luger, Ingham, Suffolk; and R. H. Masfen, Pondeford, Staffordshire, who thus speak to the merits of this entry: "A pen of extraordinary sheep"—"Such sheep! Good looks, or rather expressive, almost amounting to intelligence, nearly perfect, uniform in every respect, and I think the best pen of sheep ever sent from Merton to the Smithfield Show"—"They cantered away from the rest. Upon this the Judges were unanimous." Mr. Woods, Lord Walsingham's steward, also supplied the following particulars for the Club Report: "In the champion pen one of the three was by the highly-commended shearling ram at the Plymouth Royal meeting, and therefore half-brother to the Cup wethers of 1867; another was by the 2nd prize York ram, and therefore equally akin to the Cup wethers of 1864; and the third by the 1st prize two-shear ram at Bury, the sire of the Smithfield Club and Liverpool Cup wethers of last year."

PLATE VI.

FOXES *versus* RABBITS.

The day, I believe, is not far distant when the Legislature will seek to more strictly enforce the principle as to rabbits not being game, but in the interim a deal may be done by talking about it. Many landlords have, to their honour, voluntarily given up their claim to these pests of the farm, now that they know the great injury they cause, and others will have to follow so good a lead. The weak place, so far as England is concerned, is no doubt

in the House of Commons; as only look at the front "the Farmers' Friends" have lately offered there. Mr. Green has spoken in the highest possible terms of that Police-Gamekeeper Act; Mr. Newdegate has mourned over the calumnies in circulation against game-preserving, and Colonel Brise said farmers were fond of sport. But not one of them denounced the hares and rabbits; for, as Lord Granville says, "none of the county

members come within a hundred miles of such a question, and he only feared lest he should be regarded as occupying the position of the fool who rushed in where angels feared to tread." But these angels will most assuredly have to try their footing here, or it will get very hot for them hereafter; and when we find men like Lord Granville himself and Sir George Wombwell speaking out so strongly, we may be well warranted in looking about for more like them. And, then, as to the fox-killer, show

him up whenever you have a chance, as the Berkshire yeoman did the Gentleman-in-Waiting at Windsor, or cut him dead as the parson of the parish did; for no man who assassinates a fox can be ever worth knowing. And bear in mind, while these little wretches, the rabbits, are multiplying exceedingly, foxes in certain parts are getting very scarce.—From a Paper read by HENRY CORBET, at the Farmers' Club.

THE MOISTURE IN DRY SOILS AND CLIMATES.

BY CUTHBERT W. JOHNSON, F.R.S.

There are few important questions more interesting to the agriculturist than the moisture of his soils. There are, indeed, hardly any lands in which the supply of their watery portion may not be so altered as to materially increase their produce. Take, for instance, our grass lands—compare the lands of the grass growing counties of the west of England with a yearly average rainfall of 40 inches (equal to 4,000 tons per acre), with similar soils of our far drier eastern counties, where grass lands are found only in a very limited proportion, and where the annual rainfall is only about 20 inches, or 2,000 tons of water per acre; and then ask if there is any reason for this difference in the proportion of grass lands, except the widely different supply of moisture? And again, why do the great irrigators, who hold their farms on our great chalk formation, so carefully avail themselves of the brilliant springs which arise in that well farmed district? The water they employ on their noble water meads is free from organic matter, its chief constituent is carbonate of lime (about 20 grains in the gallon); but on a chalk soil this we can hardly consider to be a manure; and yet these springs, as soon as they arise from the earth, are found to spread fertility over large districts of, otherwise, inferior pastures. Then again, why do we in Croydon in our sewage irrigated meads find that our Italian rye grass will not yield its maximum amount of grass (say about 80 tons, or more, per annum) without we keep the land in a certain degree of moisture—viz., by yearly applying from 3,000 to 6,000 tons of sewage, equal to a rainfall of from 30 to 60 inches per acre? They would hardly need so copious a supply of liquid manure for the sake of its organic matters, in fact, hardly any amount of the richest manure would induce such a growth of grass as is here raised by the sewage.

The question, so important to all landholders, has not escaped the attention of the Royal Agricultural Society of England. This great association (we may proudly feel the greatest agricultural society in existence), has directed its attention to one of the most important branches of the inquiry, viz., "The retention of moisture in the soil of arable soils in dry climates," and for a valuable essay on this subject they have awarded a prize to Mr. Robert Vallentine, of Burcott (*Jour. Roy. Ag. Soc.*, 2nd series, vol. v., p. 336). The question on which our author has so well and so practically written, is, I opine, hardly exhausted by the conditions of the Society. It might well, I incline to think, be extended to include the *absorption* as well as the retention of the atmospheric moisture. Nature (ever in a good humour to instruct the farmer) here again lends her aid. She shows him, that the *insensible* watery vapour of the atmosphere is not deposited on all his lands alike—for instance, the dew, so valuable to his crops on dry soils and counties, is not found on all portions of

his farm in equal amount; near the sea for instance, or adjoining rivers, the insensible moisture in the atmosphere is more considerable, and the deposit of dew in their neighbourhood more extensive than on fields not very far removed. Even in the broiling climate of India, where at certain times dew is almost unknown, even there, during every night dew is found near to running waters. We may here pause to remind ourselves, that in our dry eastern corn-growing counties the farmer notices that, near the sea and near to certain rivers, his crops of wheat are, in general, of rather superior value.

Now, it is the insensible moisture to which it may be useful to direct our inquiry. And it may chance that the result will suggest some experimental examinations not unlikely to produce profitable results. First, let us briefly pause to remember the proportion of the water always present in the air we breathe. On the very threshold of our inquiry a startling fact presents itself, the *varying amount* of this insensible watery vapour, and (what looks very little indeed like a *chance arrangement*) the extent of that moisture is by far the greatest when other sources of supply to vegetation are not present, and our crops need it the most. Let us carefully note the result of the examinations of the atmospheric vapour, made at the Royal Observatory, at Greenwich, by Mr. J. H. Belville (*Manual of Thermometer*, p. 19).

The mean amount of insensible moisture in a cubic foot of the atmosphere at 9 a.m. and 3 p.m. is given in the following table in grains; it is the result of observations during seven years.

	9 a.m.	3 p.m.
January	2.70	3.84
February	3.58	2.72
March	2.77	2.85
April	3.26	3.37
May	4.02	4.06
June	4.71	4.78
July	5.07	5.26
August	5.00	5.07
September	4.66	4.77
October	3.96	4.01
November	3.27	3.43
December	2.78	2.89

The reader will here remark how, by Creative beneficence, the amount of the insensible moisture of the air, of which our crops so copiously avail themselves, is about twice as much in June, July, and August as in the winter months; so that in summer, when the other sources of supply of moisture to plant are commonly withheld, this is increased.

And again, not only is there this insensible moisture placed in the atmosphere, but there is contained in all soils, however poor and however *apparently* devoid of any moisture, the power of absorbing moisture from the air.

And what Davy long since proved (*Elem. Agri. Chem.*, p. 183), this power *increases* with the *value* of the soil. He remarked truly enough that, after having examined many soils, he had found that the extent of atmospheric moisture they absorbed was ever the greatest in the richest lands; so that he thought it was one good method of judging of the productiveness of a soil. Thus he found that 1,000 parts of a celebrated soil from East Lothian, when first dried in a temperature of 212 deg., and then placed in an atmosphere saturated with moisture at a temperature of 62 deg., gained 18 grains.

1,000 parts of a fertile soil from the valley of the Parret gained 16 grains.

1,000 grains of a soil from Mersea, in Essex, worth 45s. an acre, gained 13 grains.

1,000 grains of a coarse sand, worth 15s. an acre, gained only 8 grains.

1,000 grains of the soil of Bagahot Heath gained only 3 grains.

This absorbent power of our soils is apparently ever in action; for I never found any soils (after even the longest absence of rain) but what contained a certain amount of moisture. To give the result of only some experiments: It was on the 6th of August, in 1864, that, having noticed how well the crops, the timber-trees, and the shrubs seemed to withstand the very dry weather, I made the following experiments, to ascertain the amount of water present in the dry soils around my house at Croydon. When these specimens were taken, there had been scarcely any rain for several weeks, only 0.43 of an inch of rain having fallen at Croydon in the previous July, and not any in August till the specimens of different soils were collected; and it is remarkable that during five or six weeks, from July 1 to August 6, there were not more than four or five nights that any dew fell. The eight specimens I examined were as follows: No. 1 was a black, gravelly soil, from immediately under the turf of an old park. This soil is about 5 inches in depth, resting upon a bed of coarse gravel about 4 feet thick. No. 2 was from a bank of the Isle of Thanet sand, planted with young timber-trees. No. 3 was from the chalk soil of an old pasture, immediately below the turf. No. 4 was from a kitchen garden whose soil is the Isle of Thanet sand: this specimen was taken from the surface of a bed on which Regent potatoes were growing. No. 5 was from the soil of the same bed, taken 9 inches from the surface. No. 6 was blowing sand taken from some excavations near the East Croydon station. No. 7 was from a field of the London basin clay. No. 8 was from a bed of black sandy gravel, copiously dressed with cocoa-nut fibre. Equal weights of these soils were carefully pulverized, and exposed for some hours to a heat of 212 deg. Upon again being weighed, they had all lost weight; and calculating that the weight of an acre of soil 10 inches deep is equal to 1,000 tons, then the amount of water contained in these soils (all in appearance quite devoid of moisture) was equal, in these experiments—No. 1, soil under turf, to about 20 tons of water per acre; No. 2, Thanet sand, 10 tons; No. 3, chalk soil, 5 tons; No. 4, potato soil, from surface, 5 tons; No. 5, same soil, nine inches from the surface, 30 tons; No. 6, blowing sand, 7½ tons; No. 7, London clay, pulverized, 40 tons; No. 8, cocoa-nut fibre and soil, 41 tons. At the time these experiments were made there had hardly been any rain for forty days. From the 29th of June till the 6th of August it only rained on eight days; and the total amount of rain-water during that time was only fifty-five tons per acre, or on an average about seven tons of water each day that any rain fell. These showers merely moistened the surface of the ground, and were speedily dried off. The water, therefore, which remained in the soils when I examined them would apparently only have been

maintained by their absorption of the watery vapour of the atmosphere.

And as I have in another place had occasion to remark, when speaking of the absorption of the watery vapour by our soils, we must not forget that this deposition of water is not confined to the *surface* of the soil. Wherever the atmospheric air can freely penetrate, there the deposition of the dew, under favourable circumstances, takes place. This also often occurs in the interior of the soil, when evaporation is taking place from the surface. The amount of the dew deposited upon the soil has been estimated by Dr. Dalton to be equal to five inches per annum, or about 500 tons of water per acre. Less dew is usually formed during the first than in the second portion of the night. The amount of water deposited in dew varies at different seasons and localities. Autumn, as Mr. Steinmütz observes, is remarkable for its heavy dews, owing to the depression of the temperature during the nights. These are sometimes so abundant as to admit of measurement in the rain-gauge. In one night, towards the end of September, Luke Howard got one-hundredth of an inch of water from the dew, and in the last six days of October eleven-hundredths from copious dews and mists. We must not then forget that dew is only one form in which the aqueous vapour of the atmosphere is deposited on the earth for the service of vegetation. We have seen that when soils are dried in a temperature of 212 deg., and exposed on their surfaces to air saturated with moisture, they absorb very considerable portions of water. Suppose a soil which weighs about 1,000 tons per acre is pulverized so as to be freely permeable by the atmosphere, and that such a soil, after being thoroughly dried, is exposed to the air, then we find from the experiments of Schubler that it will absorb water, in 24 hours (being a still greater amount than in the trials of Davy)—

If a sandy clay, equal to.....	26 tons.
If a loamy clay, "	30 "
If a stiff clay, "	36 "
If a garden mould, "	45 "

We may conclude, then, that the more deeply a soil is pulverized, the more copious will, in certain states of the atmosphere, be the supply of moisture from the air; and let us not forget that this deposition is commonly in warm weather greater *under* the surface than on the surface of the land, simply because it is the cooler portion of the soil. To give an instance, when (at Croydon) at 9 o'clock in the morning of the 7th of June, 1869, the temperature of the air in the shade, on a northern aspect, was 78 degs., at a depth of 12 inches the earth was only 53 degs. At Chiswick, when the air was 78 degs., the earth was 68 degs. On the 5th of July, when at Croydon the thermometer indicated 78 degs. in the air, it was only 55 degs. at 12 inches in the earth. On the same day at Chiswick, when the temperature of the air was 80 degs. that of the earth at 12 inches was 68 degs.

We may well then concur with Mr. Vallentine when at the commencement of his essay he remarks:

"The most essential step towards causing the retention of moisture in arable land is to obtain a good depth of well-cultivated soil. All clay soils, and all such as rest upon clay or have a hard impervious pan or subsoil within a few inches of the surface, require, in the first place, *draining*, which must be followed by deep cultivation of some sort when the ground is sufficiently dry to crumble into pieces.

"It certainly at first sight appears paradoxical to speak of draining land as a means of enabling it to retain moisture; but when the various effects which drainage has upon land are duly considered, there is no real absurdity in the matter. Without considering it necessary to enter fully into the theory and practice of

drainage, I must mention a few leading points on the advantages of draining all impervious subsoils.

"The great object of draining is to relieve the soil of an excess of moisture, so as to allow rain-water to filter through the land instead of standing too long, or running over the surface. A good deal of land when being drained is found to have a comparatively dry subsoil to what the surface has, and so dense as to prevent water readily passing through it. After draining, however, air passages are formed, and water follows at once, when there is any pressure from the surface. Thoroughly drained, well-cultivated land allows any excess of moisture to pass away during wet periods, whilst it also has the power of retaining a store of moisture for periods of drought.

"All ordinary root crops thrive best with a good supply of moisture, and even oats and barley not unfrequently suffer from drought. The best naturally fertile soils are of such a texture that they require no artificial draining, and seldom become either too wet or too dry. Light sandy soils, on the other hand, have too much natural drainage, and are chiefly a trouble from retaining too little moisture. Clay loams by drainage and superior cultivation are rendered well adapted for root crops, though such soils at one time were considered quite unsuitable for them.

"After the drainage of such land as requires it, the next most important step for retaining moisture is *deep-cultivation*. Whether this may be accomplished by steam or horse power is immaterial, so that the operations are carried on at the proper time, when the soil is dry, or comparatively so. To manage this always is next to impossible; but to be able to do so generally requires no more than a full strength of horses or steam properly applied. The labour of the farm must always be kept well forward."

"Presuming," Mr. Vallentine adds, "that a farm is in such a state of cleanliness that there is no real mass of couch anywhere, autumn ploughing should be as deep as the nature of the soil will admit of. If the subsoil is very poor or stubborn, subsoil ploughing, or stirring, is preferable to a very deep furrow, which would bring too much inferior soil to the surface. Subsoiling always does good if the land is quite dry, or at least dry enough to crumble to pieces as the plough works through it. Like every other operation, however, subsoiling may be attempted at a wrong time, and mischief naturally follows. I have erred in this way more than once, and have seen frequent instances of failure resulting from subsoiling when the land was too wet, and after being cut up by the share, fall closely down again and made a mess of by the horses' feet. Land can seldom be suited for subsoiling after the middle of November, and not often so late in the season as this. Yet how many have continued this work during the whole winter?"

"With a good strength upon a farm, one field might be subsoil-ploughed every ordinary autumn, until the whole of the arable land has been stirred to a depth of at least a foot. After this the depth of the surface furrow should be increased gradually at every rotation for green cropping. It is quite an exception for land to be ploughed deeper than from four to five inches. Now, instead of this, if the soil be deepened to eight inches by degrees, the increase power it will have for *retaining moisture* will be very great, and the chance of obtaining heavy crops of all kinds increased in like proportion. It must, however, be assumed that the due manuring of the land must also be attended to.

"Autumn dunging for green crops on all clay soils or stiff loams is also much to be recommended. All soils dunged in autumn or winter retain moisture better for use in dry weather than such as are undunged. Indeed, there

are some soils so very retentive of moisture, after winter manuring, that it would be better avoided, especially if the land contains any couch which requires getting out in spring. Any good system may be abused at times, and there is nothing much worse than dunging foul land at any time. There are many good plans carried out systematically, such as subsoil ploughing, deep ordinary ploughing, dunging in autumn, &c., when every circumstance is suitable; but on the other hand, any of these operations may be carried on improperly, loss, coupled with disappointment, being the natural result.

"Light sandy soils, and all such as are usually known by the name of light soils, should not, I think, be dunged in winter. I have seen better crops of roots grown after dunging in June than after autumn dunged land, the weight of dung applied in both cases being the same."

The cultivation of turnips on the flat and on the ridge systems, in their relation to the moisture of the soil, did not escape Mr. Vallentine's attention. He remarks: "It has frequently been a matter of discussion whether turnips should be grown *on ridges*, or on the *flat surface*. I think it would be useless to attempt to enter largely upon this subject. On dry sandy soils, in dry climates, moisture is certainly retained better by sowing on the *flat* than on *high ridges*. A great deal depends upon how the various operations are conducted. By slovenly, or at least by dilatory turnip-growers, more moisture is allowed to escape during the preparation and sowing of turnips upon the *flat*, than is lost by a better course of management when the cultivation is on the *ridge* system. The ridges may generally be so rolled down as to be nearly meeting, with a depression between them of only a few inches. In such case there is little more chance for moisture to escape than by the flat system. The ridge system allows the manure to be placed more directly under the seed than by the broad-cast method. It also allows of a much cheaper and more efficient system of cultivation. However important a root crop may be, it is not more so than that the land should be thoroughly cleaned, well stirred, and completely cultivated during the growth of the crop which is to be the foundation, and, by good cultivation, the very ground-work of three or four crops afterwards. When roots are grown on the *flat*, no deep cultivation can take place. A mere surface-scratching is about all that can be done, or at least all that is generally done. Where the *flat* system of growing roots is adopted, the land is seldom kept so clean through a rotation of crops, as where ridging prevails. Many people contend that heavier crops *may* be grown on the flat than on ridges; still, it is well known that heavier crops have generally *been* grown on ridges when the system has been properly carried out."

I am not aware of any extensive experiments that have hitherto been made, as to the effect produced on the absorbing or retaining power of a soil for moisture, by dressing it with certain deliquescent salts. Every gardener is aware that if he dresses the surface of his asparagus or cabbage beds with common salt (especially if with that made from sea water), then the surface of the soil is, for a considerable time, more moist than the adjoining unsalted beds. Whether, too, the spray of the sea carried on to the lands adjoining the shore may not produce some portion of the beneficial influence to which I have before alluded, in the case of sea shore farms, is worthy of our serious attention. It is very certain that other saline matters, such as the nitrate of lime and the chloride of lime, possess far more powerful deliquescent properties than common salt; and the chloride of lime must be obtainable in the waste of the calico bleacher to a very large extent, and at a very reasonable rate.

Some years have now elapsed since I found that when

1,000 parts of the rich soil of a field in Essex, 12 miles from the sea, previously dried in a temperature of 212 degs., when exposed to air saturated with moisture gained in three hours 27 parts; 1,000 parts of the soil of an adjoining portion of the same field, which had been dressed with 12 bushels of salt per acre, gained 27 parts. In the same period

1,000 parts of some refuse marine salt gained	40½ parts.
1,000 parts soot	39 "
1,000 of horse-dung (dried at 100 degs.)	145 "
1,000 of cow-dung	130 "
1,000 of pig-dung	190 "
1,000 of sheep-dung	81 "

These examinations, imperfect as they are, may lead to other and far more valuable researches. We have been

reminded as we have travelled together through this little paper, what great things have been accomplished in the regulation of the supply of moisture to our grass and other lands. Such successes may well prompt us to believe that not only is the addition to and the preservation of that moisture in our arable soils far more within our power than we are generally inclined to believe, but that such additions to their fertility will in all reasonable probability be at no distant day profitably accomplished.

For a long series of years I have most carefully avoided making disparaging personal remarks, or entering into any public controversy; and this must explain to the Rev. H. Moule why I respectfully abstain from remarking upon his temperately written note in the *Mark Lane Express* of the 24th of January, in which he very naturally expresses his admiration of the earth closet system.

DAIRY FARMING.

BY THE NORTHERN FARMER.

Introductory.—In the United Kingdom the dairy occupies an exceedingly prominent and important position, and is a branch of industry well suited to both the climate and soil of many districts of the country, as well as to the means and requirements of the farmers who make it a leading branch of business. Mildness and humidity of climate, and fertility of soil, are essential requisites for profitable dairy farming, the former being eminently conducive to the health and well-doing of the best and most useful breeds of cattle, while the latter is indispensable for providing a full bite of succulent herbage for the summer months, and for raising those root crops in sufficient abundance which are to provide food for winter and spring.

To the small farmer of limited means a dairy offers many inducements, even apart from favourable conditions of climate, soil, and facility for the disposal of his produce. Capital invested in agriculture being for the most part locked up for some considerable time, it is difficult for the needy or struggling man ever to attain anything but a very moderate degree of success, if indeed he can get on at all by even the most untiring industry. When, however, a portion of his small capital is invested in the purchase of milking stock, and a part of the farm laid out to suit them, the return is immediate, and from this source money is conveniently got to meet the weekly payments for labour, house, and other incidental expenses, much inconvenience being thus escaped which would be altogether unavoidable in the case of having to wait for the ripening of the cereals.

It is highly necessary in establishing a dairy to take into very careful consideration the class of animals that will suit the farm, it being much better to get them of a size rather under than over the capabilities of the soil, as in that case improvement will begin at once; whereas, if the opposite has been the case, the stock must recede. This rule applies to all the breeds and varieties of the domestic animals; and its recognition in purchasing breeding stock will not fail of bringing about most successful results. A man possessed of large capital can easily place on his land animals of immense bone and substance, and of the most approved breeds; but he cannot so easily alter the character of his soil, and make it fit to carry such cattle; that must be a work of time, however great may be the expenditure with the view of improvement; and, consequently, it becomes good sound policy to keep both stock and soil progressing in the same ratio. If the dairy is to be the leading source of profit, and its

produce in the utmost obtainable quantity the sole object, independent of all other considerations, a breed of cattle should be selected famed for its large milking capacity, no animal being retained in the stock, which, after a fair trial, has been proved to be a poor milker, her produce not paying for keep and attendance. On the other hand, when milk and butter do not take first place, the rearing of young cattle being carefully attended to as a source of revenue, a more valuable breed will be desirable, one which reaches maturity at an early age, so that in whatever condition the animals are sold off the farm, whether as stores or fit for the butcher, they may bring remunerative prices.

For a purely milking dairy, and more especially on soils of light or medium quality, the Ayrshire can scarcely be excelled. This breed is characterized by hardiness and activity, the cows keeping themselves in good condition, and giving a large quantity of milk in proportion to the consumption of food. The most serious objection to keeping large-framed cattle on land light of surface, is the tendency they have to lose flesh while milking largely; the actual loss in money value of the animal herself, being little more than met by the whole season's produce. The Ayrshire is just constituted to meet this difficulty, her compact and tidy frame being easily kept up; her coat is always shiny and healthy looking, unless positively starved outright, and the close of the season invariably finds her in blooming condition. For the combined dairy no cross need be desired better than that between a Short-horn bull and Ayrshire cow, both animals being pure specimens of the breed which they represent. The stock thus bred are exceedingly valuable for every purpose, as they inherit the large milking capability of the one parent and the fattening properties of the other. In every case where the object of the farmer is two-fold, the herd should be sufficiently well bred to permit of the way-going animals to be fattened and cleared off at the age of two years, so that the permanent stock of milkers may be interfered with as little as possible, and a full bite preserved for them. The very fact of the breeder having it in his power to do this by the use of first-class male animals, ought to be one of the strongest inducements to his keeping only the best, and utterly ignoring those which are cross-bred. Pure breeding we thus find tends largely to economy of food, by conducting to early maturity; and materially quickens the return of capital. A heifer or bullock, the sire of which was pure-bred, will in general bring as much money at the age

of two years as could be obtained for it a year later had both parents been cross-bred. If it suits to clear off the young spare stock only in store condition, the superiority is quite as marked, proportionately large prices being received according to quality, and, moreover, they are always saleable. On dairy farms, where the cattle are carefully bred, with a view more especially to the profitable production of milk, and where it is not convenient to feed the spare stock, very good results may be obtained by rearing the heifer calves only, retaining them on the farm until they have milked two seasons, and then disposing of them as they approach their third calving time. Being now in their very prime they can easily be sold at remunerative prices, well repaying their breeder for his skill and trouble. And if the possession of merely young animals gives a little more trouble, and scarcely perhaps such a large annual return, yet the high price received on the average for the off-going stock amply makes up for the difference. When this mode is followed there are never any aged cows to weed out, which must be sold for a few pounds, the loss in value making a serious inroad on the animals' produce for the previous season. Being successful in obtaining big prices affords much encouragement to rear as many calves as circumstances will permit, and acts as a powerful inducement to breed carefully, and get a name for turning out thriving beasts, good specimens of the breed to which they belong.

Selection of a Bull.—The surprising influence for good which the male of pure descent, whatever the breed, exercises on the quality and character of the future offspring being now well understood, no effort should be spared to procure purely-bred bulls, and on no consideration should a cross-bred animal be used. The extra price is not worth a thought, as by the time the progeny of the pure-bred bull have reached the age of twelve months they will have paid not only the difference between the pure and the cross but the entire value of their sire, and that without either extra feeding or attention. No difficulty need be experienced in getting breeding animals of the right stamp, as they are pretty equally distributed; but should it happen that a little trouble is necessary, it should be cheerfully undertaken. No amount of care will make up for want of breeding; and it is most unpleasant for those in attendance to be putting good food in bad skins, knowing, as they well do, that the results to their employer can never be anything but unsatisfactory. When the stock are crossed, no home-bred bull should be used on any pretence whatever, however well-looking he may be; however compact in frame, or hardy of constitution; or however well descended he may happen to be from animals of rare milking property—all should be overlooked, and the beast got rid of, as if used the stock will recede instead of progressing. Breeding from cross-bred bulls destroys uniformity; the cows become unshapely, losing the fine level back, finely sprung rib, and general squareness of body, which are so eminently the characteristics of purely-bred cattle. They are also much larger consumers of food—a consideration no one can afford to overlook—very soon after passing their prime, getting a raggedly and uneven appearance, and requiring a very large amount of food to keep them at all in decent condition. At the present day there is no difficulty in procuring young Shorthorn bulls of pure descent, and at prices within the reach of men of very moderate means indeed. This blood being now so universally diffused over the kingdom, and possessed by those who have the good sense neither to pamper nor over-feed, rearing their young stock in exactly the same way as they are likely to be treated by those who purchase them for breeding purposes, a great boon has been conferred on all stock farmers of limited capital. Bulls reared in this way are not only

to be had for far less money than those which have been pampered, but they also turn out to be far more useful, being really serviceable animals for the purpose for which they are wanted, and their progeny healthy and thriving. To sum up this part of a very important and interesting subject, we consider that a better foundation, or starting point, for profitable dairy farming can scarcely be attained than that which begins with the Ayrshire cow and Shorthorn bull. In uplands, where the pasture is but indifferent, and situation exposed and unsheltered, the Shorthorn is then inadmissible, the pure Ayrshire giving more profitable results.

Treatment of the Calf.—A considerable expenditure of time, trouble, and money having been gone to in procuring good blood, the offspring becomes valuable before it has seen the light; and it therefore becomes well worth while to bestow much care on the cows during the months of gestation, removing as much as possible all disturbing influences, so that the calf may come to the world healthy and full-timed. When the breed is valuable, much loss is too frequently experienced from premature births, as from whatever cause it begins in the herd, it seldom ceases without a considerable number of the cows slinking, there being an apparent, though hitherto unexplained sympathy amongst a number of breeding cows, the conditions of whose daily life is exactly similar. Regularity of feeding, good ventilation, and abundant room, not only in the stalls, but in the width of the doors, so that there need be no crushing as they go in and out, are all excellent preventives of abortion. Musty hay or straw, more particularly barley-straw in almost any condition, given as food to in-calf cows, is provocative of slinking, and should be avoided, as also the giving of a quantity of cold roots as the first feed in the morning (frosted turnips are particularly objectionable), a little sweet hay or fresh oat straw being safest for the morning feed, and accidents less likely to occur by such an arrangement. The calf having been brought into the world healthy, the great aim should be to keep it so, and this can in general be successfully done by providing it with comfortable quarters, and feeding moderately at regular intervals. When the disposal of dairy produce is more the object than stock-rearing, the latter being subordinate to the former, and the calf consequently intended to be brought up by hand, it should, to save trouble, be removed from the mother the moment she has licked it dry. It should not be permitted to suck even once, and the instincts of mother and offspring never having been aroused, they have no knowledge of each other, and much annoyance is thereby avoided. Although in theory it may seem to serve several useful purposes to permit of the calf sucking its dam for a day or two, yet the trouble afterwards is so great in getting the one to let down her milk, and the other to drink out of the pail, that the good which might be expected to result from doing so becomes quite neutralized. The beatings can be quite as easily given by hand as by suckling, and are in this way quite as effectual in clearing the stomach and intestines, and establishing that healthy action so vitally necessary for the very existence of the creature so recently come into the world. When the calf has never been permitted to suck its mother there is not the slightest trouble in getting it to drink out of the pail—hunger will make it do so; whereas if it has sucked at all, it shows the greatest obstinacy in learning, and cannot be got to drink freely until a considerable time has elapsed. With the cow herself there is also some trouble, and very often positive danger from retention of the milk when she has taken kindly to the calf, and her maternal instincts thoroughly aroused. For several days she will scarcely let down her milk at all, rendering it almost impossible to milk her clean, and, from this reason alone, severe inflammation is

liable to set in, resulting, not only in a great deal of temporary inconvenience, but actual monetary loss. Should the swelling become hard, and not yield to repeated and long-continued fomentation with hot water, the following mixture forms probably as good an ointment as could be used for soothing the pain, and reducing the inflammation. Camphor, 1 oz., rubbed down with a little spirits of wine, and well mixed with 1oz. of mercurial ointment, and $\frac{1}{2}$ lb. of elder ointment. This should be rubbed well in after each milking, but clean washed off with warm water before being again milked. To the owner of a large stock of cows, the above receipt is very valuable, and a few pots should be kept ready mixed for use. A number of cows in a herd with blind paps is most unsightly; besides being a pecuniary loss by injuring the milking qualities, and lessening the value of each animal so blemished when parted with; and moreover it is not creditable, and therefore the utmost care should be taken to keep down inflammation at the period of calving. If at all possible the calf-house should be subdivided, so that each little animal can have a separate compartment for itself—an arrangement which adds most materially to its comfort and progress, and through which much after trouble and many losses from death can be avoided. To give the calf a good start, and lay the foundation of a good constitution, the milk should be given undiluted and warm from the cow for the first fortnight, the third and fourth weeks half new and half skim; afterwards the skim itself will answer admirably, and as the season advances the thickened milk does equally well. When given in sufficient quantity, coagulated milk fattens amazingly, many lots of calves so fed being fit for the butcher when turned out to shift for themselves. The most dangerous and insidious disease to which young and rapidly-thriving animals are subject is black-quarter, which, when it breaks out, very frequently commits sad havoc before it can be checked, making the loss very serious when the cattle are particularly well bred. It gives so little warning that remedial measures are usually of little avail, and therefore on those pastures liable to its periodical appearance amongst the young stock whatever can be done in the way of prevention should on no account be neglected. Dry-lying in the field is essential as a preventive, and care not to shift too suddenly from moderate keep to rich and succulent pastures, as blood-striking is almost sure to follow. A seton in the dewlap is strongly recommended by many distinguished veterinarians, and as we have ourselves often tried it, and lost none when the precaution has been used, we consider it worth while recording the mode of using it. So as to render the cord more irritating it should be made specially for the purpose, with one-half hemp and the other half horse-hair, and in substance about the thickness of ordinary fencing-wire. When thus made, the seton does not require to be rubbed with Venice turpentine or cantharides ointment, the irritation which it induces being quite enough for the purpose required. In inserting the seton a little care is necessary to avoid the blood-vessels, which can be done by taking the dewlap between the finger and thumb, and ascertaining the exact point at which the flesh terminates, underneath which the puncture should be made and the cord introduced, a couple of tight knots being put on each end to prevent its slipping out. At intervals the cords should be examined, and drawn back and forward with some degree of force to prevent clogging and assist the discharge. As we have already noticed, damp bottoms are a fruitful source of black-quarter, and according as they are rendered dry by drainage, this dire disease becomes less frequent in its attacks, and of a milder and less fatal type. In situations difficult of improvement housing by night should be resorted to very early in autumn, so as to obviate as much

as possible the injurious effects of the damp soil and chilling frosty dews.

The Supply of Food.—As the cow is fed so will her produce be greater or less, profitable or otherwise, is an axiom pretty well known to most people whose business is amongst dairy stock. Yet notwithstanding this, there cannot be a doubt in the mind of even a very superficial observer, that there are many owners of milking cattle who act as if the contrary were the case, and that it was of comparatively little importance whether the food given was up to the mark in either quantity or quality. Too frequently but little winter food is prepared, and the poor animals have to drag out a cheerless existence on whatever rough grass they may be able to gather from the pastures they occupied in summer, with the addition of a little straw or coarse hay when in the house; the modicum of turnips or mangolds grown being reserved for advanced spring, when the cows are at or near the calving. By the time they drop their calves, the cows thus treated are so reduced in condition as to render them quite unfit for giving a full season's milk, so much of the food supplied having to go to the nourishment of an enfeebled system, and to repair the waste of tissue caused by a lengthened period of semi-starvation. Now such treatment is the very reverse of the teachings of reason and common sense, as the cow being an animal than which there is none more grateful for liberal treatment, or gives a more overflowing return, arrangements should be made for an abundant supply of nourishing and succulent food during all seasons, so that each and every member of the herd shall have enough to eat every day in the year. Without full feeding no cow, however good may be her milking qualities, will remain long in full profit; therefore, keeping her on a short-supply of food is just so much lost time, and loss of income to her owner. If, from unforeseen causes, food happens to be scarce at the calving season, it is better policy to sell a few of the cows and so be enabled to feed those well which are retained, than endeavour by pinching to keep all on, and endanger the entire season's produce by prematurely drying the flow of milk; a result inevitable if the food is limited at the period of calving. Nay, so important is it that there should not be the slightest approach to hunger, or even restriction, that with the money so obtained, if cash is not obtainable in any other way, it is better to purchase food, whether in the shape of grains, oilcake, turnips, or hay, and by supplementing the home-grown food stretch it so far as to give a full supply until the season has become sufficiently advanced, and it can be procured in other ways on the farm. During the summer months the pastures are of course the principal dependence for dairy stock, and on soils remarkable for fertility nothing else is required, and summer-house feeding is unknown, large-framed splendid cattle being kept in blooming condition and in full profit on grass alone. Very different, however, is the case of the farmer who farms on a medium soil, the grass of which gets burned up when overtaken by a lengthened drought, as if he has not provided supplementary food, his cattle cannot possibly give a profitable return, falling rapidly off both in produce and condition. Growing a few successive breadths of green food to be given in the house at the morning and evening milking pays well, as it not only increases the flow of milk for the time being, but keeps it up till a much more advanced period of the season than is the case when the cows have to subsist on the pastures alone. The large quantity of manure made by the partial house-feeding system is another source of profit, as it gives the farmer the means of sustaining the fertility of his land, making it in fact self-supporting, but little money being required to be spent on fertilisers of any kind when substantial farm-yard manure of the best sort is manufactured so extensively. At one time we supposed that it

was an impossibility, even with the utmost care and forethought, to provide such a regular supply as would ensure a hearty feed twice a day from the time the roots were finished in May, until again available in September; but a neighbour of our own has shown the fallacy of that idea by keeping a stock of about fifty head for the past seven or eight years without letting them into the fields even for a single night during the entire year. Tares, irrigated grass, and second-crop clover are his principal dependences for house food; and so well does he manage that he has every beast fat, from the youngest-calved heifer to the oldest cow. Winter tares sown in September are a valuable crop, giving a large amount of food, and permitting the ground to be cleared in time for a full crop of turnips. Tares have this useful property, that however succulent, they do not scour cows fed on them, and may be given fresh from the scythe without injury; indeed, there is no way they can be given so appetizing to the animals as when newly cut. They do not so much increase the flow of milk as add to its richness, and sustains it throughout the season, the butter made being firm in texture and delicious in quality. On ordinary land tares are not worth growing for cattle-feeding purposes, unless highly manured, the crop having no bulk, and moreover runs too late in the season to be of any perceptible benefit. Much of the profit of a dairy is lost by keeping the cows out in the fields at night too far into the autumn, as they are chilled by the frosty dews, and the milk prematurely dried. This course is compulsory on those who have provided too limited a supply of food for a protracted winter, and are therefore forced to leave them out too long, and turn out in spring too early. Housing in time assists greatly to keep up the milk, and to continue it at the paying point well into the winter. It is obvious that when cows are turned out during cold wet nights in October they can little else but look for the best shelter the fences will afford, and there lie down; and a very small allowance of food given inside, will be equal to what they can collect in the fields, even when the nights are moderately fine. In October butter is getting scarce and the price rising; therefore it pays to look to the comfort of the cattle, and feed fairly both in-doors and out, if it can at all be managed, which it can be, if the necessary measures have been taken. By this kind of treatment towards the close of the season, we come to the conclusion that as much money may be made extra as to convert what otherwise would have been but a middling season into an exceedingly prosperous one. In bringing cows through the winter it is of great benefit to their health to get a run out every day for a few hours, the exercise promotes circulation, prevents swollen joints, and tends to hardness of constitution, besides improving the quality of their produce in the case of those which are milking. When dry the winter food of the in-calf cow may with great propriety consist of a morning and evening feed of roots (carefully avoiding frosted turnips) and as much oaten-straw as she will eat. This treatment regularly kept up will bring her to the calving in fine condition, enabling her to give milk in paying quantity, rich in quality, and therefore highly productive of butter. Although farmers holding rich land look upon turnip growing for dairy stock as an expensive process, and trust more to the large crops of hay they can grow than to roots; yet the upland farmer cannot in this way afford to imitate his more fortunate neighbour in doing so. Not being able to grow on light land more than half the crop of hay that the other can with perfect ease, the article becomes to him a most expensive one, and he must make green crop his main stay, the character of his soil giving him the opportunity of doing so, and rendering roots the most economical food he can raise. When calved, hay can be substituted for straw, and the quantity of roots

increased to about 100 lbs. given in three feeds, a weight of roots quite sufficient for the heaviest cow. Some attention should be given in the commencement to avoid surfeit, as serious injury to the animal may be the result of over-feeding, and in any case, if the food should be rejected for a time, the produce is liable to suffer a very serious diminution. In early spring, while the cows are still wholly dependent on house-feeding, those newly calved are exceeding grateful for the addition of a little concentrated food, in the shape of crushed oats, meal, bran, or oilcake. When mangolds are used it is absolutely imperative to give meal or crushed oats, as milk from them alone is very thin and unproductive; and again, those roots having a decided tendency to scour, the meal acts as a corrective, and the animals are kept in good health and condition. There is a striking difference between cream from the milk of merely root-fed cows and that from cows getting corn-meal or cake in addition; the one is comparatively thin and poor, while the other is thick and rich, affording ample proof of its superiority by comparison alone, before being submitted to the conclusive test of the churn.

House Accommodation.—In the stalls provision should be made to keep up such an amount of heat as will keep the inmates comfortable, care being taken that too high a temperature is not maintained, as they will sweat and be under such a constant sense of oppression as will not only keep them uncomfortable, but prove in the end injurious to their health. From 55 to 60 degrees of night heat will promote both health and comfort, and materially aid in the production of milk, none of the food being wasted by having to restore the natural heat of the system, which is dissipated by the cold temperature in which the cattle are compelled to remain. Draughts should be carefully avoided, a newly-calved cow being highly susceptible of injury from cold currents of air; and to prevent cutting draughts there is nothing so effectual as a properly-organised system of ventilation. There should on no account be any side opening underneath the level of the occupants of the stall, a mistake too often made, and the fruitful cause of much mischief. A series of minute openings, easily made in the building of the wall by the insertion of hollow bricks or even drain pipes of small bore, should extend the whole length of the building for the admission of fresh air, the outflow of that which has become vitiated being provided for by ventilators placed along the ridge of the roof, or by raising the top row of slates a few inches, which can be easily done, looks well, and answers the purpose admirably. In the division of the stalls, perfection appears to us to have been reached by the different manufacturers in iron, who make stable and cow-stall fitting a portion of their business, their models being exceedingly worthy of inspection and study by those who are about to build or remodel. They almost, without exception, combine security of fastening with safety to the animals, comfortable standing room, and excellent facility for preserving the bed clean and dry. Being rather expensive they are almost out of the reach of ordinary tenant-farmers, but with cheaper materials the style could be kept sufficiently well in view to serve the purpose.

The Dairy.—A dairy is popularly supposed to be a structure combining neatness with elegance, while at the same time it affords every possible convenience for the preservation of milk and cream until manufactured into butter. Beautiful dairies are certainly not scarce, but they are mostly in connection with the establishments of wealthy families, who take a special pride in having the dairy a model of cleanliness and good order, and fitted up with every contrivance that will save labour, and enable the dairy-maid to have everything connected with her department in first-class condition, fit at all times for inspection, besides supplying cream and butter for the

family of the very best quality. The ordinary farmer, however, is very differently situated in this respect, his dairy being too frequently a mere make-shift, in no way adapted to the purpose for which it is used: circumscribed in its limits, with low roof, damp floor, and incomplete ventilation, it is almost impossible to preserve that thorough state of cleanliness so indispensable for the production of high class butter. It is clear that an improperly constructed dairy must be most inimical to the farmer's interests, being the fruitful cause of much butter of indifferent quality, the lower price at which it must be sold taking a goodly slice off the annual receipts. For the convenience of those concerned in its management, and for the sake of having the milk removed to the vessels in which it is to be set with as little agitation as possible, and before being too much cooled, it is obvious that the milk-house should be situated conveniently to both the dwelling-house and milking-stalls. At the same time it should be completely removed from the manure heap; or if it must unavoidably be in the range of buildings which surround the cattle-yards, there should be no communication on that side, isolation so as to secure freedom from the gases evolved by the fermentation of manure being imperative. A north or north-west aspect is very suitable, and if at all practicable the ground should slope away from the dairy with so much of a fall as to render it an impossibility to have such a thing as stagnant water in its neighbourhood. It is not necessary that the erection for this purpose should be large, as space can be economised by having a double tier of shelves; therefore a somewhat long and narrow house is preferable to one which is nearly square, centre space, especially where there is a churning-room attached, not being so much an object. The floor should be laid with tiles in preference to flags, as having been submitted to the action of fire they tend to preserve that dryness of atmosphere so essential to success; while flags, however suitable they may be in other respects, attract damp, invariably sweating on the approach of rain, and continuing moist and clammy during the prevalence of wet weather. A thorough draught should be obtained, if possible, so as to keep the air pure and fresh, the taint imparted by confined air being fatal to sweetness in the products of the dairy. Openings at opposite sides ensure this when the situation permits. When, however, there are only admissible on one side, ventilators must be placed on the ridge of the roof. Instead of these openings being glazed, perforated zinc should be neatly fitted, which, admitting air and light abundantly, excludes dust, flies, and all objectionable matters which may be floating about. Wooden shutters will be found useful during high winds, and for the exclusion of frost. A hot-water pipe carried round the house is of the greatest service in winter, enabling the temperature to be regulated, so as to get the cream to rise quickly and in full quantity, extreme cold being very prejudicial to its separation from the milk. In connection with, and having a door opening into the dairy, there should be a small room for churning and washing the butter and preparing it for sale. This is a most useful addition, and should not be done without if possible, as, if the operations which should be conducted here are performed in the dairy proper, it becomes almost impossible to preserve the purity and sweetness of air so essentially requisite. The floor of this room should be so constructed as to carry off the water without stagnation, the channel which conveys it going through the wall, and then communicating with a drain. On no account should the latter open into the house by being carried underneath the wall, as, however carefully managed, foul gases will be driven back, and the air inside become vitiated in consequence. The scalding-house should have no connection whatever with the dairy or

churning-room, but should invariably be entered by a separate door.

Utensils of the Dairy.—There is very great diversity of opinion with regard to the best material for the coolers or vessels which contain the milk while it remains in the dairy, china, glass, wood, earthenware, zinc, and tinned iron having all supporters, and all having something to recommend them, either on the score of economy or usefulness. China bowls being the most ornamental, are found on the shelves of those dairies which we have already had occasion to notice; but are never seen in the possession of ordinary farmers. Glass is an excellent material for a milk-pan, and would appear from experiments which have been made to have a certain advantage over other materials, in conducing to the rising of the cream. Notwithstanding this, they do not seem to have come into such general use as might have been anticipated, probably on account of the first cost being considerable, and from a natural fear of their being easily broken; which we believe, however, is not really the case. The brown ware pan recommends itself by reason of its cheapness, and is a favourite; it is easily cleaned, and if a few breakages do occur in the season, the expense of replacing them is but trifling. Wooden coolers are also largely used, and are, probably on account of their lasting nature, the most economical of all milk vessels. When kept as they ought to be they are highly ornamental; the hoops bright as silver, and the oak scoured white as snow, affording a pleasing contrast. They have also the great advantage of preserving the natural warmth of the milk much longer in a low temperature, a quality which adds to their merit in no small degree. When temporarily out of use a little water may be placed in them, so that the hoops will not loosen, which they are apt to do in very hard dry weather. Attention to this little matter will render a well-made oak cooler almost imperishable. Shallow rather than deep vessels are the most suitable, the cream rising more quickly. This formation is exactly found in the wooden cooler as usually made; and vessels of other material which are made in the same form are best adapted for the dairy. The churn has of late years come as near perfection as it seems possible to bring it; and certainly in the hands of those accustomed to its use, the forming of the butter can be regulated to a minute, the quality of the article being superb when good sweet cream is used. It is of no advantage to bring the butter quickly, as by doing so the quantity is less and the quality inferior. To have substantial butter, firm in texture, rich in colour, and of good keeping quality, and moreover so as to extract all the butter which the cream contains, the process of churning should occupy not less than half an hour: and will frequently run on to the full hour if the temperature is rather under the mark, which is as nearly as possible 60 degrees. For ease of working and simplicity of action there is no form to equal the barrel churn, as sent out by the best English makers; and it seems by general acceptance to be the universal favourite. About 80lbs. can be easily churned by manual labour when the axle of the churn is mounted on a single little roller to ease the friction; and in practice there is not the slightest difficulty in getting the butter out of this style of churn, nor is there the slightest inconvenience experienced in cleaning it.

Management of the Cream and Butter.—Much bad butter is made by permitting the cream to stand too long before being skimmed, putrefaction having commenced, the taint of which no after manipulation can wholly remove. This is done too frequently from the mistaken notion that if skimmed too soon the whole of the cream will not have time to rise, and butter of indifferent quality is habitually made, the parties doing so arguing that what is lost in quality is gained in quantity—a species of self-deception

which results in much loss. To assist the churning process, there is no objection to the cream being soured; and the butter is in no way injured thereby, perfectly sweet cream being seldom used during summer unless for a very particular purpose. During the summer months there is some difficulty in having the temperature sufficiently low, and in consequence cold water must be brought into requisition very abundantly to reduce the cream to the proper standard. Filling the churn with cold spring-water over night, and plunging the cream crocks into large tubs of the same, saves all trouble, the butter having the firmness and consistency of that made in the autumn. So effectual is this mode of management that even where ice can be cheaply and conveniently obtained, it need seldom be used. In situations where cold spring water has to be brought a considerable distance, and is consequently very valuable, a few pounds of ice is exceedingly useful on churning days, saving a great deal of trouble, besides enabling the dairy maid to produce a first class article. The butter on being removed from the churn should be washed in the iced water until the whole of the butter-milk is expressed, which is easily known by the water running off at last clear and pure.

If the milk has been properly strained when brought in from the cow (an operation which ought on no account to be omitted) there will be no hairs or other impurities in the butter; and it is now ready for being salted. One imperial pint of salt to about twelve pounds of butter is quite enough to preserve it for any length of time that may be required; if for immediate use, half the quantity will be sufficient.

It is not at all impossible but that butter which, when taken from the churn was of superior quality, may, from imperfect salting and packing, be inferior by the time it is offered for sale. Much care should, therefore, be taken in intimately blending the salt with the butter, so that it

shall not be streaked or imperfectly mixed, any appearance of this being fatal to its fetching the top price.

It should also be firmly packed, each lump being thrown into the cask with considerable force, and further packed firm with a rammer. This has the effect of uniting the entire body of butter into a solid mass, and forcing off the brine, both important matters in promoting the keeping qualities of this extremely delicate and easily injured article. Winter-made butter, especially where the cows are supplied with a large quantity of roots, is very difficult to obtain of superior quality; yet we consider that it is not impossible to have sweet butter during the whole of that season; and that without even once recognising the unpleasant taste of turnips. This can be accomplished by putting a very small pinch of saltpetre to each pan of milk; strict cleanliness; and, above all, churning often; skimming the milk after it has stood not longer than 36 hours. Granting that a little more butter might be made by letting it stand longer, that slight loss is amply compensated by superior quality and by the greater value of the milk, which being so sweet commands a higher price than if it had stood for 24 hours longer. However tedious the process of churning may sometimes be in very cold weather, it must not be unduly hastened by the addition of warm water, as that brings out the bitter turnip taste, besides destroying the colour and texture of the butter—making it, in fact, almost worthless.

Great care is required to attain success in the management of a dairy; but if there is one thing more than another necessary, that is attention to cleanliness. Unless this point is rigidly attended to it is vain to expect success. Entire failure may not be the result of its absence in whole or in part; but the highest amount of profit, pleasure, and satisfaction which it is capable of yielding will fail to be realized.

THE IRISH LAND BILL.

For some months past we have, with what may have looked like "curious care," endeavoured to keep as clear as possible of the Irish Land Question. And we have done so under every kind of temptation to break through our reserve. Scarcely a day has passed, more especially of late, without our receiving a letter or a pamphlet on the subject, wherein the English and Irish systems of tenure have been too often mixed up in inextricable confusion, the difficulty of any adjustment only increased, and confusion rendered worse confounded. With some knowledge of the Sister Kingdom, for we have traversed it from one end to the other; and with some considerable experience of the action of Tenant Right in England, for we have tabulated every existing Custom that can be spoken to, an inclination to criticise the critics has been almost irresistible. But we have felt from the first that in this matter the two countries could not be kept too distinct, as we should have almost preferred that any discussion over the tenants' claims in England stood over until those of the Irish occupier were arranged.

It is in the outset a very manifest truism that the Irish Land Question is of so peculiar a nature as to require altogether peculiar treatment. Any proposed remedy could under no circumstances be rendered in its entirety beneficially applicable to any other part of the United Kingdom, and any consequent comparison of usage here or there becomes something worse than idle and useless. The Irish gentleman has now for generations only contrived to "live" at a gradual sacrifice of his position as a

landlord. This is a fact that we must accept not only on the word of the economist or the politician, but quite as forcibly on the evidence of the story-teller and the dramatist. His improvidence had become a proverb, his embarrassments a normal state of existence. He drew every shilling he could from his property, and then left it to the keeping of others. From such a state of things there sprang a system with which we in England have, happily, but little practical acquaintance. The absentee created the middleman, and the tenant called upon to perform the landlord's duties by the land came to acquire an interest in it far beyond what would be implied by his occupation. "In Ireland the landlord does not, as a rule, find the capital necessary for the improvement of the soil," said Mr. Gladstone, in the opening of his address the other evening, and this sentence supplies the very key to the case. We hear, with something more than a mere feeling of surprise, of the Irish farmer claiming a right to sell his good-will, of his maintaining his right to something like fixity of tenure, and so forth; and we are often enough inclined to attribute such preposterous demands to the turbulent, dissatisfied character of the people. But it is not so. The Irish tenant has long been more than a tenant. To adopt a phrase just now in fashion, his dealings with his landlord have partaken much of the nature of a co-operative movement. So far as the actual holding has been concerned he has been both landlord and tenant. He has not only cultivated the land, but he has built the house and homestead, he has

made every improvement that has been made, and so long as he has paid his rent he has remained undisturbed in possession. And from this false state of society have grown up Customs which would sound elsewhere altogether obnoxious and unwarrantable. The man refuses to be disturbed, or, if he be, he advances claims that would seem on the face of it to interfere with the rights of property. But, then, it must be remembered how much his extraordinary labours have done for that property, and how closely they have identified him with its permanent improvement.

So long as the tenant continued in possession, if only the stronger grew his hold, no great difficulty could well arise. But of late years, as the Premier tells us, emigration from Ireland has been but "another word for banishment;" while a receipt for rent in the case of many a small occupier, has had from time to time a notice to quit on the other side of the paper. The man thus lives in a perpetual state of unprofitable uncertainty and unwholesome excitement; and small must be our surprise if he become restless and disaffected. The deeper we look into this question, the more cause do we see for its consideration, and the action which the Government has taken over it. But we can happily go further. Of all the pamphlets, essays, letters or reports we have met with, we know of none to compare with the speech of Mr. Gladstone. He has seized the monster with the grasp of a statesman; and while he relieves the people, he is careful to do so at no outrage of their feelings or their habits. The remedy, as we said, is one peculiar to Ireland; but the effect will be felt further on. Where Custom is justified in its origin and beneficial in its effect, let Custom have the force of law. It is remarkable, indeed, how happily Mr. Gladstone has interpreted the *better* part of the Tenant Right principle. To establish *right* there must be *improvement*, or, as he laconically defines it, "improvement, in the first place, must add to the letting value of the land, and, in the second place, be suitable to the holding." It will be found throughout the whole of his admirable exposition how this proof of improvement is insisted on before compensation is admitted; how clearly the line is drawn between temporary and permanent improvements, and how carefully the landlord's position is guarded, as to making the more expensive outlay himself or being duly consulted before this be incurred. So far, and the Irish and English Tenant-Right would seem to be very nicely assimilated. The Irish claim, however, of course goes further, and the Ulster Custom is countenanced. By this the evicted tenant is entitled to be paid not only for his improvements, but for his good-will, and this to an English eye will look like the weak place in the fence. Through the force of such an enactment the in-comer will of necessity wrap up his talent in a napkin; he will pay so much to come in that he will only receive again

when he goes out, and hence a large proportion of his capital will remain unemployed. In fact, the payment for good-will in Ireland has precisely the same effect as the payment for acts of husbandry in certain parts of England. But the new Land Bill is keenly alive to this evil, and would free the people from it by every possible means. Instead of a yearly tenancy let the occupier have a long lease, and fairly work his own again out of the land; or with so heavy a lien already upon it, let him be encouraged to make the purchase outright. Or, on the other hand, let the landlord be assisted in buying up these now obsolete and burdensome rights, justified though they were in a bygone age when the Irish tenant, like the Australian squatter, settled himself upon and did everything for the land—but call it his own. Capricious evictions are discountenanced, if not more directly penalised, the smaller the holding the greater the protection; and security of outlay will at any rate answer for security of possession. And in this country, security of capital and security of tenure work on to precisely the same end.

So far we must be understood as speaking rather to its brilliant introduction than to the measure itself; although we have little fear but that one will be worthy of the other. The Premier's speech, more especially, may be carefully studied alike by the English and Irish agriculturist, for it is very pregnant with matter. Let, indeed, the Irish Land question be adjusted, and, so far as man can do, this would look already something like an accomplished fact, and England's turn is pretty certain to follow. We recognize this promise equally in the speech from the throne as in that of the Premier: "The measures proposed with respect to the ownership of land for the consideration of Parliament during the present Session are not exclusively contained in the present Bill. Some of them are included in other Bills, for they do not apply to Ireland alone, but to the whole kingdom. Among them will be measures for facilitating the transfer of land and for dealing with the succession in cases of intestacy, giving greater ease, liberty, and justice to the operation of the law than in its present state it can be said to possess. It is possible that there may be some other provisions analogous to these, which we may deal with during the present Session, and which will be applicable to the whole of the United Kingdom; because in reference to them we consider the circumstances of the three countries to be so analogous as to warrant our dealing with them together." So said Mr. Gladstone significantly enough on Tuesday evening; while some years since the Farmers' Club said unanimously enough that "the difficulties attending the transfer of land have generally become so many and embarrassing as to demand the serious attention of the Legislature, with a view to removing them." And further, that the first and most direct means would be "the simplification of titles and forms of conveyance."

HOP GROWING IN THE COLONIES.

Our antipodean brethren are going a-head, and are ambitious of rivalling the mother country in some of her industries; they desire, in fact, to be thoroughly independent of foreign supplies, so far at least as their labour power and the capabilities of soil and climate will permit. In excellent wool they have long shown us what they can do. They have even a superabundance of wine and wheat for export, and they are striving now might and main to supply our hungry mouths here with cheap beef and mutton, cooked and uncooked. They are even

competing with the English farmer in the production of beet-root sugar for their own consumption. The latest project is to grow hops which shall displace imported hops, and enable them to establish breweries more generally, so that Australian ale and stout may take the place of the well known drinks of Burton, London, and Dublin. All these endeavours are creditable to young States, and we wish their efforts all success; but as regards hop-growing in most of the colonies we find more in the way of theory than of practice: more of what may be done than of

what has been done. And it should be borne in mind (as experience even is proving) that the whole of the Australian colonies are no more adapted to the growth of the hop, than are the whole of the counties of England.

In Otago a conference of agriculturists was lately suggested on the subject of hop-growing, for which it is believed the climate of that province is peculiarly adapted. At Nelson hop-growing has advanced a stage further than in Otago. A brewer in that province cultivated last year 8½ acres, which produced 15,000 lbs. of hops, yielding in the local market at the current value of 3s. 6d. per lb. £2,625, or equal to £308 per acre. It is not to be expected that this price can be always obtained, but even at 2s. per lb. the result would be highly remunerative, and the latter price is the lowest at which good hops have yet been sold in New Zealand. The average import of hops to the port of Nelson from London alone during the past three years is stated at from 40,000 to 50,000 lbs., and when to these figures is added a large quantity obtained from Melbourne and Sydney, it will be seen that there is sufficient consumption to encourage a fair trial being given to this branch of agriculture. The yield and price of hops given here are both above the average, but we are not disposed to be hypercritical in such a case.

The account of what has been done with hop-growing in Victoria is not by any means encouraging. The efforts made to grow the plant in the Melbourne Botanical Gardens, under the skilful direction of Dr. Muller, do not seem to have been attended with success, which is much regretted, as Victoria pays annually over £70,000 to England, Tasmania, and America for this valuable product. But what if it should be found that there is no spot in Victoria fit for the growth of the hop to perfection? What if the climate should be found too dry and hot for this purpose? This supposition is in part negated by what we are told of hop-growing in New South Wales, where the growth of the plant is said to be most astonishing in favourable spots. "Sets" planted in September have been known to produce five cwt. per acre the following March. This was at Illawarra, almost a semi-tropical district. But as a set-off to this luxuriant production, it may be mentioned that little is ever heard of any extensive hop plantations in New South Wales, and although hop growing has been tried in South Australia, where the climate is not very dissimilar, it has not proved a commercial success. Even in Tasmania, where the climate is confessedly so well adapted to the growth of the hop, and where the hop-grounds are sheltered from the winds blowing from every point of the compass by high hills, irrigation is required, and the utmost care in every other respect to ensure success. A visit to the Tasmanian hop plantations at New Norfolk would well repay the cost and time bestowed on it by those who think of trying hop-culture in the neighbouring colonies. It is in fact to Tasmania alone that they must look for their supply of hops, as most suited in every way for their successful and profitable production.

In a few years time New Norfolk will be a most extensive hop garden, for the growers are all extending their plantations. A few practical facts connected with the system of cultivation adopted in the colony may be interesting to growers here, where the seasons are different, and where the bulk of the ground employed has been for centuries under cultivation. In Tasmania the ground to be transformed into hop gardens is almost virgin soil, and an immense amount of care is necessary in its preparation to ensure profitable crops. The hop is a slender climbing plant, which requires a very rich mellow soil and an unlimited amount of attention to ensure success; but there is no other crop known which will so well or so surely repay the

labour and capital expended. It is a maxim with successful hop growers that you cannot expend too much labour, or use too much manure on a hop garden, and a very satisfactory proof of the truth of it was afforded last season at Fenton Forest. It was thought that the owner was carrying the principle to extremes, but the result fully justified his efforts, as he picked nearly £800 worth of hops from an acre and three-quarters of land. The piece was cultivated as an experiment, and from £60 to £70 was laid out upon it last season. It was, however, an exceptional piece of land, and had been used for many years as a bedding place for cattle. The ground was thickly covered with stable dung, a few loads of guano being also used; it was then copiously irrigated and kept clean by the free use of the scarifier, the yield being slightly over 30 cwt. to the acre. Such a result ought to be a great encouragement to intending hop-growers, and is the best proof that can be given of the remunerative nature of the pursuit when properly carried on.

The soil of a hop garden must be rich in its nature, and rich to a considerable depth, or if it is not, it must be made so. The slender roots of the hop plant strike deep into the soil and creep along over the subsoil, forming a complete web, or net-work over the whole land. These roots are composed of the most delicate fibres, and the more carefully they are nourished the stronger will the plants become. In choosing ground it is necessary to examine carefully the nature of the subsoil, which must be dry and sound. A clay subsoil is unfitted for hops, and will not yield a profitable return.

The system of preparation adopted by most of the large growers at New Norfolk is as follows: The ground is ploughed two furrows deep, or from 12 to 14 inches, and care is taken to see that the land is moved equally all over its surface. The ground having been ploughed, the scarifier is brought into requisition, and it is made as fine as possible. The land is then laid out into parallel lines, either six or seven feet apart, and short sticks are set up at the same distance along the rows, so as to alternate between them, and mark the place where the sets are to be planted. Most of the plants are put in six feet apart each way, but where the ground is particularly strong seven feet should be allowed, as air and sun are indispensable to the plants; and an overgrowth of bine in a confined space would choke them and stunt the crop. In planting the sets a hole should be dug about two feet square, and this should be filled up lightly with earth dug out, and a compost of earth, lime, and dung; but it should be observed that this is well decomposed, as fresh dung should never be applied to hop plants. The place being thus prepared the plants may be dibbled in three together about six inches apart, and forming an equilateral triangle. A watering with liquid manure will assist the roots, and the plants will soon begin to show bines. Prior to planting the "sets" must be carefully pruned and intermediate eyes notched out, as otherwise runners will show, which may cause considerable trouble. The number of plants usually set to an acre is about 3,600. The hop is a *dicocious* plant, some of the individuals being male and others female, and these have respectively flowers of a different construction and character. The male, or stamiferous flowers, which grow on stalks quite distinct from the female flowers, prepare the pollen or fertilizing dust, and afterwards wither away, committing the dust to the air, to be conveyed to the ovule of the female. A bushel of hops, grown in a garden where male plants were near, has been known to weigh over thirty-six pounds, whilst those from a garden where the males were generally eradicated weighed only twenty-two pounds. In addition to this advantage, however, the aroma of hops which have been impregnated with the pollen of the male is superior, and the strength of the

bitter much greater. It is necessary, therefore, in planting hops to see that a proper supply of male plants is secured. At New Norfolk they are now plentiful in all the gardens, and at Valleyfield they are planted at the rate of one in every hundred, every tenth plant in every tenth row being a male. As the pollen is remarkably light, and apt to be wafted away, it is also customary in some gardens to set a few male hops among the hedges to secure more perfect impregnation. In reference to the best descriptions of hop to plant the finest quality is, of course, the Golden tops of old Kent; next to that comes the White bine, or Grape hop, but perhaps the best standard variety for general growth is the Colegate hop.

Of these the New Norfolk growers have a very large quantity, and they are found a strong healthy plant giving a generous crop.

The seasons into which the work of the hop gardens may be divided in Tasmania are as follows: Preparing ground, June and July; planting, July and August; poling, September and October; training and hoeing, October, November, and December; picking, March, April, and May; scarifying and cleaning ground always. The cost of raising hops, of course, depends upon the amount of labour bestowed, and the means adopted to improve the soil. The average expense under ordinary circumstances at New Norfolk, is estimated at £30 per acre.

ARE CATTLE SHOWS AND PLOUGHING MATCHES ADVANTAGEOUS TO AGRICULTURE?

At the usual quarterly meeting of the Ayrshire Farmers' Club, Mr. Robert Dalglish, Templeland Main, Auchinleck, president of the Society, in the chair,

Mr. CALDWELL, Knockhoggie, read the following paper—Competition has long been the acknowledged medium by which the relative merits of almost everything submitted to it has been determined; and it is generally recognised as a safe, sure, easy, and practicable way of doing it. We find that competition leads and stimulates the greater part of mankind to put forth energies and to arrive at a degree of perfection in whatever they are aiming at, which otherwise would scarcely be attainable. Competition at school stirs and animates the undeveloped powers of the young mind, thereby hastening and perfecting its education. Competition in business blesses and balances society. The subject of discussion at this meeting is in the form of a question, "Whether cattle shows and ploughing, as at present conducted, are advantageous to agriculture?" My answer is in the affirmative. Extend to me, then, your patience while I support this opinion by a few remarks.

Ploughing matches are held for the purpose of encouraging and rewarding by premiums those who excel in the art of turning up the soil in the way best adapted for producing a good crop, and for most effectually keeping down grass and weeds. The ploughing which practical judges approve of is that which is straight, evenly held, well packed, the grass well put in, the seams between the furrows close and clean, the seed-bed as deep as possible at the given width of furrow, the furrows so set that when measured the face or socket of the furrow will measure about half an inch more than the back or cutter-cut, the finish neat and narrow, and the ridge so ploughed that when you stoop and take an angle view over it every furrow will meet your eye in its proper order. Many of you have heard that the pane of the furrow should describe an angle of 45 degrees; but this is a shape of furrow I have never seen, and so acute an angle is altogether impracticable. The shape of furrow that good judges approve of is, I find, about 60 degrees. If cut much more acute the pane will be too thin, the back weak, and the furrows will want that body and substance necessary to give the ploughing the required solidity. If cut much more rectangular or square we lose that depth of seed-bed and twine of furrow so much prized in first-class ploughing, and the nearer we approach the square, brick-shaped furrow the plough gradually loses command, the grass is near the top, the furrows sit on their edge, and are generally badly closed and shaky. This latter is, in my opinion, the worse of the two extremes. A new era has dawned by the introduction of the double furrow plough. The features that commend it to our notice are speed and saving of man and horse labour; and, so far as I am able to form an opinion, the double plough on even-surfaced land will in a great measure supersede the single one. Many people thought that the double plough would not be suitable for lea ploughing; but the work performed by it at the various matches has been so satisfactory as to remove such prejudices from unbiased minds; and we may now look upon it as an established, economical, and labour saving implement. There is no doubt but that there is room for improvement in this implement. We cannot expect perfec-

tion yet, any more than there was with the reaping-machine when first introduced; but I confidently hope that ere long our energetic and persevering local implement makers and plough doctors, when educated at the public seminary of competition, will bring them to the same pitch of perfection to which they have brought the single one. Allow me, then, to close this part of my subject by stating that as everything that is worth doing is worth doing well, so also is ploughing. I believe that we are indebted in a great measure to ploughing matches for the uniform good ploughing to be seen everywhere throughout the country, and also for the almost unexceptionably good working of the ploughs now-a-days. By these matches we know where to get good ploughmen and good ploughmakers when wanted. Competition has placed Ayrshire ploughmen at the top of the tree, for we find on two occasions where a number of them were pitted against an equal number from Renfrewshire, Ayrshire was the first, and on the next occasion sustained her pre-eminence; and on Tuesday week one of Ayrshire's sons, who has been well trained in the school of competitions, carried off first honours in the open Derby ploughing at Johnstone against half a hundred from other quarters. I now pass to the other division of my subject. Cattle shows are, and have been, held for the ostensible purpose of stimulating and in some measure rewarding the owners and breeders of the different animals whose properties and qualities are best adapted to the objects for which they are required in agriculture. For instance, the properties of a Clydesdale horse are soundness of wind and limb, strength of body and bone, with symmetry and action. The properties of the sheep are quantity and quality of wool and mutton. As the Ayrshire milk cows are the objects of the greatest interest and attraction, and as time will not admit of entering fully into the others, I propose to confine my remarks to this class. The properties which our judges approve of, and which, I beg to say, I endorse, are as follows: The head of the cow short, and wide at the forehead; the eyes prominent, clear, and expressive; the horns long, strong, high, and curved back; the neck long, and fine at its connection with the head, and free from loose skin or dew lap; the back straight from the roots of the horns to the tail, the shoulder thin at the top; the forequarters light, the middle short and deep, widening and deepening backwards, with well-arched ribs, filling well up behind the shoulder blade; the hind quarters long, the hock bones wide apart and somewhat prominent, with wide haunches, broad short thighs, tapering to a small, clean, wiry bone under the knee; the skin moderately thin and elastic, the bran close, soft and curly, with a silky feel; the milk veins well developed, the milk vessel long, wide, and well attached to the body, the sole or under surface a plane and running parallel to the swell of the belly; the vessel, well rounded and firmly bound up behind with four moderately-sized, cork-shaped, plumb-hanging teats, so planted that when viewed from behind one-half of the space is between the teats, and the other two quarters outside, and when viewed from the side one-third is before, one-third between, and the remaining third behind. I admit that some of these properties, such as the size or shape

of the head and horns, the shape of vessel, or size and formation of teats, have nothing to do with the milk-giving properties of the animal. These go to constitute beauty, and when we get the elements of beauty and usefulness combined, we have a specimen of the prize-taking, milk-giving, money-bringing, pure-bred Ayrshire cow, not only valuable to sell, but often more truly valuable to keep as a breeder. Some discussion has lately arisen as to the best size of cows, some alleging that judges did not attach so much importance to it as it deserved. Size has always been regarded as a point of merit, but certainly not as a leading one by judges, nor do I think it has any right to be, for we find that size has little to do either with the milk-giving or money-bringing properties of the cow, and we find that different sizes are adapted to different soils and climates—that the smaller-sized one is best suited for bare clay soils and upland districts, and the larger sized one for the fertile plain. The greater number of farmers breed young cattle for filling up their stock when the aged or those that fall out of tid are withdrawn, hence it follows that from the abundance of winter feeding and luxuriance of pasture, or, on the other hand, from scarcity in winter and indifferent pasture in summer, as the case may be, Nature in this, as in many other things, beautifully adapts the size of the cow to the requirements of soil, climate, and quality of feeding. Those in favour of the larger-sized cow say that as all come to the shambles at last there is a loss in the smaller-sized one. This objection is, I think, more imaginary than real, for we find that a given quantity of feeding sufficient to feed five of the former will do six of the latter, the aggregate weight being nearly equal, the difference being in number only. Some allege that with all our shows the cattle are deteriorating in size and quality. To this doctrine I do not subscribe. I find that, in 1837, there were 38 entries for aged cows and three-year-old cows at the Ayrshire Show, and in 1868 there were 116 entries of the same age. I venture to say that in the former year Ayrshire could not have turned out such a number of beautiful well-bred cows as was shown in 1868 and 1869; and I likewise hazard the opinion that those specimens which carried away the premiums have never previously been surpassed, for be it remembered that in 1868 and 1869 Ayrshire competitors won and retained first and second placed in the open show against all comers. Allow me, in conclusion, to say that we will do well to cultivate, to keep pure, and if possible, to improve this valuable breed of cattle named after our county; and we are quite safe to accept and endorse those points of excellence to which judges give precedence, for we find that judges are not fanciful theorists, but selected from amongst the most interested, practical, and experienced of the agricultural community.

Mr. CRAIG (Polquhays) was glad to hear the double-furrow plough was taking so well amongst his low country friends. He hoped they would soon be able to bring it to the mountainous districts also. As to the exhibitions of stock, he was perfectly convinced that Mr. Caldwell had taken the right view. His description of the Ayrshire cow might not please every one, but it was the one generally adopted by the judges, and contributed greatly to the beauty of Ayrshire animals. There were a few points that might be criticised from the weight-making point of view. For instance, he did not think that short heads contributed so much as some breeders imagined to the making of a useful animal. He thought the head should be a little longer than the present fashion. With a small head they were sure to have a small animal. Otherwise he thought the description of the cow was particularly good. One of the chief benefits of shows in his opinion had been to teach the public what to breed from, and the form of animal that would be best for them to rear. Where the judges were properly selected, all who came to the show-yard had an opportunity of seeing the animal that was considered the best by men of knowledge and skill.

Mr. TENNANT (Creoch) thought cattle shows were very useful in raising the standard of their ideas in reference to cattle, and in making them more careful in their selection of breeding animals. He believed also that a pure-bred Ayrshire animal that would gain a prize would be a more kindly feeder and be more valuable for all purposes—either for milking, fattening, or producing cross-bred animals for fattening.

Mr. REID (Monkton Mill) said it did not occur to him that Mr. Caldwell, in speaking of the cow's head meant a small

head, but rather a good broad growthy head, and with that he entirely agreed.

Mr. SMITH, jun. (Mosablown) said he highly approved of the description of ploughing. He had heard it remarked that a furrow cut in a rectangular form was easier drawn by the plough; but he had always thought that a good working plough cutting a good furrow which came right over was both easier drawn by the horses and easier on the man. He had heard it said that as much of the furrow should be below the seed as above it; but he thought with a rectangular plough there was too much of the furrow above the seed, because it left the seed loose, and it got down till nearly all the furrow was above it.

Mr. ROBERTSON (Ryeburn) entirely coincided with Mr. Caldwell's views. His description of a well-ploughed ridge had been most minutely given. But he remembered when he was learning to plough, that he could get more people to tell him what a well-ploughed rig ought to be than he could get to tell him how to do it. That was always the objection he had to ploughing matches and also to cattle shows and cheese shows, that there was not enough of benefit given to the public by those who were successful competitors. He remembered that the man who could take a first, second, or third prize in ploughing was sometimes in the habit of going six or eight miles to a smithy, and nobody saw his plough, or the particular angle of his sock or the point of his coulter. He kept all that to himself. Consequently, like many other ploughmen, he (Mr. R.) laboured for a while in the dark. He thought if it was made a condition in all these ploughing matches and cattle and cheese shows that successful competitors were under a moral obligation, if not a legal one, to give their fellow members of the same society practical instructions as their mode of proceeding with their implements or cattle, then they would become useful, practical things in the country. But at present he did not know that there was much good to be derived from them. He found many good ploughmen, for instance, who could not set their own irons; and one great use of ploughing matches should be to teach them to do this. It was the same with the rearing of cattle and the manufacture of cheese. You might pay a premium of £5 or £10 to learn your dairy keeper or yourself to make first class cheese, and a thousand to one but the person with whom you learned had one little thing connected with his system which the learner was too dull to pick up, or which was intentionally kept from his view. He believed it would tend to the continuance of the success of the Ayrshire Agricultural Association if it would make it one of its standing rules that all first class prize-takers should give instructions in the process they followed at a nominal charge to their fellow members.

Mr. BROWN (Arndell) said he subscribed to every word that Mr. Caldwell had said in regard to ploughing; and were it not that he had been represented as being wrong in his ideas of ploughing, and as disapproving of those that were becoming more fashionable, he would not have added anything on the subject. Mr. Caldwell's essay had come at a very appropriate time for the makers and users of ploughs. It was evident that with the double-furrow ploughs there was something wrong at first. That was not to be wondered at; but what he did wonder at was, that men should have approved of them as they were, and of the shape of furrow that they then cut. He had no objection that a plough be made to cut four furrows at a time. He had seen it done, and the reason that it was not a great success was, that it did not shape the furrow in the way described by Mr. Caldwell. He was satisfied that if Mr. Fowler's steam plough had cut a proper triangular furrow it would have been a great success in this country for a long time. His opinion of the double-furrow plough was that whenever it was made to shape the furrow in the same way as the ordinary plough it would be a great success too. He could not speak about their being much easier drawn; he knew they were a good weight in themselves; but he was satisfied the nearer they got the furrow to that of the ordinary plough it would be the easier drawn. A plough in good trim was always easier drawn and easier held. He had no doubt the double-plough would be like the reaping machine, and that it would be brought to such perfection that it would be carried, as Mr. Craig had said, to the tops of the mountains. With regard to cattle, he thought Mr. Caldwell's description of the Ayrshire cow was almost perfect, still many of the points were not essential to good milking qualities, but were more

matters of fashion, and fashion depended on the taste of the times, and was liable to change. With regard to the breeding of cows, it had been said that it required a man to go to cattle shows to learn where to breed from. But how did they account for the fact that men who were at one time successful sowers and prize takers, and who were constantly attending cattle shows, were now nowhere in the prize list?

Mr. WHITE (East Rawa) said: They were greatly indebted to Mr. Caldwell for his able and excellent essay. His own opinion of ploughing matches was that in times past they had served a good purpose. They might sometimes have caused a little expense to farmers; but he thought that expense had not been ill-incurred. It had been the means of giving the ploughmen an interest in doing their work well, and if good ploughing was better for the crop than bad ploughing, the farmer was not without his reward. As to ploughmen not being able to put their ploughs in order themselves, he did not know that they would have been any better in that respect had there been no ploughing matches; he rather thought they would have done it more carelessly. Competitions had been useful in making plough-makers pay more attention to the implements they produced, and he thought in this way they had conducted to the benefit of agriculture generally. And now that ploughs and ploughing were undergoing a great revolution, perhaps they might have competitors after this of a different description. In order to perfect the implements and enable the men better to accomplish the work, he thought it was likely that competition would be the means that would be resorted to still. With regard to competitions in cattle, he considered they had been only beneficial where people had taken advantage of them. If they could manage to raise a stock such as had been described by Mr. Caldwell, he had no doubt they would prove more remunerative than the cattle generally produced, either in the production of dairy produce, or in the rearing of store cattle. Cattle shows had been one means of exhibiting to the public animals as near that description as they had been able to rear. No doubt many things could be said against cattle shows, and many points might be brought up in which they had not benefited the community and had not improved the breed of cattle. But would these points have been improved had cattle shows not existed? He did not think the breed would have been a bit better, and perhaps not so good. He therefore concurred with Mr. Caldwell in thinking that both cattle shows and ploughing matches had been in the time past beneficial to agriculture generally.

Mr. STEEL (Burnhead) said he believed that but for the influence of ploughing matches, instead of having three horses drawing a double-furrow plough, they might have been going on, as their fathers did 70 or 80 years ago, with the old wooden plough drawn by four horses. He did not think, for his part, that ploughmen generally were not able to set their own irons—they were both able to do that, and to tell the smith how they wanted a thing done; nor did he think there was any unwillingness on their part to give information. With regard to the breed of cattle, even apart from remunerativeness, he thought it was well to have a beautiful animal that was pleasant to look at; but he knew plenty of Ayrshire and Leicestershire farmers who, instead of getting 7s. 6d. for a sleek calf, were not able half to supply the demand made upon them, and readily got from £3 to £5 each for them. Surely that must be a great improvement in itself.

Mr. MURDOCH (Holehouse), while he approved of the principle of competition generally, thought their ploughing matches and shows had not been so well directed as they might have been. Fine ploughing and beautiful cattle were very good in their way; but he did not think they were the means of adding a shilling to their revenue. There was a great loss of time in preparing for ploughing matches and other things, and generally, those who looked on got more benefit than those who were engaged in them. They might have had some effect in giving them better implements; but great mechanical improvements had taken place in other branches of trade in which there were no such competitions. As to the great prizes sometimes given for prize cattle, it was more on account of their rarity than of any real value they possessed. Unless they gave more milk, and were worth more in the shambles, they could not see that they were more valuable; and he believed a comparison would show that they had not a superiority in these respects, but the reverse. There was great expense in preparing animals for cattle shows, and they

suffered afterwards when put out to the grass in such high condition, the grass not being equal to the feeding they had been getting in the house. If there had been benefits from ploughing matches and cattle shows, there had also been a good deal of evil.

Mr. LEES (West Carnigillan), referring to a remark of Mr. Brown that some old prize-takers were not now heard of, said it was impossible that people could always stand at the top of the list: it would be a pity if they could. When people were fortunate for a time they were apt to get careless, and others came up and passed them. With regard to the value of pure-bred stock, how many men had come from America and other places to purchase Ayrshire cattle, and their first concern was to find out who were prize-takers, and they gave them handsome prices for their stock. If they were not in the competing list they had no chance of getting their animals sold to such advantage. He had felt the benefit of this himself, and he believed the calves alone would pay the extra expense they were at. As to dairy cows, he thought the great loss of their Ayrshire cows was in having too little condition when put out to grass.

Mr. WALLACE (Braehead) said he was greatly pleased with Mr. Caldwell's paper, which appeared to him to avoid both extremes. With reference to Mr. Brown's remark about being astonished at some people being satisfied with the double-furrow plough as it was three months ago, he was one of those who had tried it, and was satisfied; and because he was satisfied with it then, he was not satisfied with it now that it had been made for ploughing lea. He had used it for ploughing wheat land, and it made better work than ever he got done with the common plough; but just because it made so good a job for wheat it did not suit lea-land. He thought that to adapt the plough for all kinds of work it would be necessary to have two sets of irons and two sets of reasts, but he did not think this would be any great loss. One advantage of the double-furrow plough was that they were less dependent for good work on the care of the ploughman. Of course, it required more attention, but a man might get on well enough with one of these ploughs who had never held a plough before. He thought ploughing matches were useful in stirring up their young men to emulation, though he did not know that they were profitable to the farmer. With regard to prize cattle, he did not think that class of animal was profitable to farmers generally. For his own part it had been always necessary for him to study to have good milk cows, but he did not go to a show-yard to find them. The real reason, he believed, why some old prize-takers gave up competing was, that they could not afford it any longer. One old prize-taker had stated that as a reason to him for giving up. He was inclined to agree with Mr. Craig about the head of the cow. He thought it was necessary that a good cow should have some size. He had sometimes bought some of these delicate prize cows, and he found that they were not of much use to him with his system of feeding till they got rid of some of their fineness. The object of a milk cow was to give milk, and the thing they should study was to rear a class of cows that would give them plenty of produce. He had often found these nice little, closed-packed cows better feeders than milkers. He remembered sending four cows, not from his own stock, to a gentleman—one of them a nice little show cow, cost £90, and the others about £16. He remarked to him that in all probability the milking qualities would be in inverse ratio to the price; and it turned out as he expected, that the £16 cow gave far more milk than the £90 one.

Mr. YOUNG (Kilhenzie) said he was a strong believer in competitive examinations in all things. His opinion was that without ploughing matches the merits of the double-furrow plough would not have been so speedily or so generally recognised. He thought cattle shows had been an advantage to the farmer in showing the breed of cattle likely to bring high prices; and he had always been given to understand that a well-bred cow was easier kept and would bring several pounds more when they came to sell her.

Mr. B. M. CUNNINGHAM (Shields) thought Mr. Caldwell's paper very good so far as it went; but it did not embrace the whole question, which was whether ploughing matches and cattle shows, as at present conducted, were conducive to the interests of agriculture. Now, that point had not been discussed, and what he would say would bear on that point specially. He admitted that competitions of all kinds

were beneficial, but the thing was to get competitions carried out in a fair and natural way, and he believed neither ploughing matches nor cattle shows were so carried out at present. He had ascertained from the Secretary of the Highland Society that the conditions on which that Society gave medals for ploughing matches were that the land should be ploughed at the rate of ten hours to the imperial acre, and that no assistance should be given to the ploughmen. Now, of all the reports of ploughing matches he had seen in the newspapers this year, he only saw one in which the time was given, and that was at the rate of 16 hours per imperial acre. Whether such a rate of ploughing as that was conducive to the interests of agriculture, he would leave them to judge. His opinion was that if a man could not plough an imperial acre of land in ten hours he was not fit for his business. Complaints were frequently made that servants did not do the amount of work they used to do, while wages were a third higher, and yet the very farmers who spoke thus were the men who encouraged their ploughmen at these matches to plough at a rate which required 16 hours to do what might be done in 10 or 8 hours. He did not think any one had attempted to show that prize-ploughed land grew any more bolls per acre than land ploughed at less expense and with less time and trouble. They should remember that lea ploughing, on which all these pains were taken, only stood for a few months. With the price at which grain now stood, they would find that they would need to study how they could lessen their outlay if they were to meet their engagements. He was glad to hear the remarks of Mr. Robertson, which were only too truthful, about people who kept their knowledge to themselves. He had himself known of individuals who had made experiments and failed, but carefully concealed the results from their neighbours. Now, this was entirely wrong. This Club, he was glad to say, was got up for the very purpose of exchanging experience, and giving it forth to their neighbours and the community through means of the press. One other thing he had observed with pain in connection with ploughing matches, and that was the kind of prizes sometimes offered. He noticed that some of the ploughmen got a bottle of whisky, or a bottle of brandy, or a pound of tobacco. Now, where he a ploughman, and were anyone to offer him a bottle of whisky or brandy, he would dash it at his feet as a deliberate insult. With regard to cattle shows, his remarks would also bear on them as they were at present conducted. One objection he had to them was that there were far too many of them. There was now one in nearly every parish. Farmers were far too much taken away from their work with these sort of things. If merchants, manufacturers, or professional men were to spend one-tenth of the time that farmers did at ploughing matches, cattle shows, fairs, and dispensing sales, they would never get on in the world with their business. He only spoke of the time that was wasted; but there was a tendency in these things to other evils. If they could get cattle shown in their natural state, there might be considerable advantages derived from cattle shows. But a person who wished to be successful must take all means possible to get his animal into the state that would gain a prize, and there was a temptation to use unscrupulous means to attain his end. Exposures of doctoring and imposition had been made in connection with the Ayrshire Association. As regarded showing cows in milk, he could never see where the real advantage was. He supposed the object was to get the best milker. Well, if cows could be shown in their natural state with ten or twelve hours' milk in their vessel, they might be able to get at whether they were likely to be good milkers or not. But it had happened hitherto that cows had been shown with too much milk on them—they were what was locally termed "hafted;" and it was generally the case that if a cow was "hafted" once, it was destroyed for life. Now, until something was done to do away with that artificialism and deception, he could not see any good to be got from their cattle shows. Mr. Caldwell had stated that the cows were better now than they were twenty years ago; but his opinion was that, whether as regarded substance, symmetry, or size, they were not to be compared with what they were twenty years ago. With regard to fat stock, letters had appeared in the agricultural papers recently, showing that the state of obesity to which animals were brought not only rendered them more liable to disease, but injured their generative functions. This must be the case with some of the cattle shown at their agri-

cultural shows. His reply to the question under discussion must be in the negative.

Mr. DALGLISH, the Chairman, said they had had a very interesting discussion, and he had no doubt that the remarks that had been made would do good. It was evident that the opinion of the majority of the meeting was in favour of ploughing matches and cattle shows, even as at present conducted; but at the same time the abuses of the system had been very strongly brought out. Their object should be to get rid of these abuses. In connection with cattle shows the great error that many people committed arose from the ambition to obtain a prize at any cost, and they often did not hesitate to keep a cow dry the whole year, and utterly spoil her milking qualities that she might take a prize. This was an extreme abuse of the system, but there were lesser abuses, such as over-feeding, which was a great error, particularly in districts like the one where he was situated, where the grass and climate could not maintain high condition unless they added artificial feeding. If they did go on giving artificial feeding summer and winter, they found the cow, if not subject to disease, at all events subject very soon to natural decay. If they could get their cattle shows to bring out only those points which were really profitable, they might have well-shaped, and at the same time really useful animals. With regard to ploughing matches, it was evident that they had derived great advantage from them, and if they were a little differently conducted, and less time lost with them, they would be still more useful. Certain individuals if allowed plenty of time could do very fine work; but place them alongside of others, where they were restricted to time, and they would be easily beaten. He was not much given to boasting, but when he was a young man he was told if he went to a ploughing match he would likely take a prize. He never tried, however (laughter); but he could plough as quick and as well as any man he ever saw. He believed there was not a furrow amongst them that would have taken a prize, but at the same time after it was harrowed you could not have known but it was prize ploughing (laughter). He thought if there was more attention paid to the ploughing of red land it would be a great improvement on the present system. Any person might plough a lea furrow if he got his dimensions and had his plough set right; but to plough a red field with the ridges thoroughly straight and a nice roll upon them, and done in such a way that a string laid across would touch every furrow, required a higher amount of skill and dexterity. The chairman, after some further remarks, concluded by saying they were all much indebted to Mr. Caldwell for his excellent production.

Mr. CALDWELL said he would briefly notice one or two statements that had been made. Mr. Murdoch objected to cattle shows because they did not cause the animal to be of any greater value to the farmer. Even admitting, for the sake of argument, that they did not give more milk, and that they were not heavier when killed, it was surely profitable to the agriculturist if when he came to sell his cattle he got a larger price for them. He thought Mr. Cunningham was rather in error in regard to the time at ploughing matches. He had been a good deal at ploughing matches, and in every case the men had to plough to time, which was generally 16 hours to the Scotch acre. He believed that was as quick a rate as stiff lea land could be ploughed at, and was as good as 10 hours to the imperial acre on Mr. Cunningham's level land. He had found that the best ploughman was generally the quickest, and that the best lea ploughman was generally the best driller and best red-land ploughman. He would only again remind them that their judges were practical men, and not likely to have a weakness for what was merely fanciful, but generally preferred what was valuable.

On the motion of Mr. YOUNG (Kilhenzie) a vote of thanks was tendered to Mr. Caldwell for his able and instructive paper.

A similar compliment was paid to the Chairman, and the meeting adjourned.

SUFFOLK AGRICULTURAL SOCIETY.—About £200 has been collected in Sudbury for town prizes in connection with the approaching meeting of the Suffolk Agricultural Association at that town.

ON THE MANAGEMENT OF SHEEP.

BY THE NORTHERN FARMER.

Of all the articles raised on the farm, few are so fluctuating in value as the produce of the flock, the variations recurring not only at intervals of a few years, but almost invariably at certain seasons in each and every year, the difference in the downward direction being sometimes so great as to cause considerable despondency in the minds of those who own this description of stock, and who, in consequence of faulty arrangements as to the supply of food, are forced to sell just at the period of depression. This is almost sure to happen with those who make a rush and get into sheep with intense enthusiasm when they are commanding large prices, assisting by so doing to raise them still higher; and by-and-by, probably in not more than two years afterwards, the produce of the flocks so hurriedly got-up is sent to market, too often merely as store lambs, or badly-finished mutton—and prices get forced down much below the paying point. This consummation cannot, of course, be brought about by a few isolated individuals pursuing the same system: but singularly enough, the periodical anxiety to get into sheep seems to be a general thing all over the country, and they being of a most prolific nature, the pastures quickly become over-stocked; and hence the desire to get rid of them is just as strong as was the anxiety to purchase. Although the breeding and feeding of sheep by amateurs does not always show the balance on the correct side of the ledger, it is, in the hands of those who stick to it and make it a regular branch of business, a very profitable investment notwithstanding. In every pursuit practice makes perfection, the management of sheep being no exception; and those who keep up a constant and regular stock are careful to provide abundance of food for all seasons, and thus being in a measure independent, they can hold until such time as the state of the markets gives them an opportunity of obtaining a remunerative price. The flockmaster who breeds his own stock, seldom permitting an admixture of strange blood, except through the rams, has many advantages over those who are constantly changing. He secures for his flock fixity of type, always a recommendation to purchasers, being at once significant of good breeding, aptitude to fatten, and freedom from disease. It shows also, and that convincingly, that care and judgment has been exercised in the selection of the parent stock; and when a certain type has been persevered with until it becomes hereditary, much credit and profit accrues therefrom. A pure-bred white-faced sheep, so carefully-bred as to present a very exact resemblance to a butter-firkin, straight along the back, broad across the quarters when viewed from behind, as well as over the loins, full and prominent between the fore-legs, and altogether evenly-balanced in both fore and hind quarters, with a good firm fleece capable of resisting a pretty severe blast and preserving the skin warm and dry, however soaked may be the surface, is the form which all should desire to attain, sparing no amount of trouble or moderate expense until perfection has been reached. With the Downs there is less difficulty in securing perfection of form, their natural shape coming much nearer to it than that of the white-faced breeds. We have long been of opinion that the most satisfactory results in a monetary point of view are to be obtained by a judicious system of crossing. The Down gives rotundity of form to the white, while the

white imparts increased size and weight, and at the same time largely benefits the fleece. Even a quarter of white blood shows immensely on the clip, the wool having all the qualities and much of the appearance of the Leicester or Lincoln, from whichever it is derived, while the general outline of the animal, and the colour of the head and legs, is but little changed from that of the pure Down. It is very undesirable to breed from cross-bred rams, leading, as it inevitably does, to deterioration in the character and usefulness of the flock; but it is by no means bad policy to breed from cross-bred ewes. When the latter possess a dash of Down blood, let it be little or much, they make exceedingly useful and highly profitable sheep; are harder than the pure white, and less injured from continuously wet weather. They make excellent nurses, the Down blood developing the milking property; their progeny having every characteristic necessary for future utility and profit. A little Lincoln blood is a very valuable accessory in a cross-bred flock, giving the wool staple, substance, and weight. It also adds to the size and stamina of the animals. Once introduced, its good effects show for a very long time, the substantial look of the fleeces more particularly always attracting especial notice.

Many of the established breeds have reached their present state of perfection through having been crossed with others which possessed in a remarkable degree the qualities in which they were more or less deficient. Thus, some of the Leicester stocks, noted for the weight of fleeces which they carry, owe that valuable quality to a slight infusion of Lincoln blood; while the now famous Border Leicester owes much of its hardness, compactness of figure, and improved milking property to the Cheviot. The resemblance is noticeable more particularly in the formation of the forehead, which is flat, smooth, and neat-looking; and in the grey colour of the face and legs, which speaks very plainly of the hardy mountaineer. The face and forehead of the English Leicester is quite distinct, being round and prominent, and the colour much lighter. Downs in the same way have been and are still crossed with each other for the purpose of effecting certain alterations in the character of the flock which may be deemed desirable or necessary. No difficulty need be experienced in laying the foundation of a good and useful flock of sheep, parties who propose getting into that kind of stock for the first time having a wide and largely-developed field to choose from. All that is necessary is to fix on the particular breed which has been proved to be most suitable for the locality, or even the particular variety of soil on which they are to be fed, whether Lincolns, Cotswolds, Leicesters, or any of the varieties of Downs; then, purchasing from a careful breeder, taking care, if possible, that the land they come from is inferior in quality, as then the improvement will be marked, beginning from almost the first day they are placed on their new pastures. Some people seem to be of opinion that sheep are a very convenient stock, requiring little care and attention; and that they are able to forage for themselves, and pick up a living where cattle would be in a state of semi-starvation. This is a most mistaken idea, which many have found out to their cost. If not properly attended to, disease of a very destructive kind is sure to break out, involving their owner in a wilderness of trouble;

and if a regular supply of food is not kept up for every season, all the profit the flock may make will be absorbed in expenses. It is only reasonable to suppose that if the animals are permitted to lose condition for want of a proper supply of food at one season, a considerable period must elapse, after it becomes abundant, before they recover what they lost; the loss in the meantime being heavy, in the case of ewes, for instance, as the fleece will be valuable only according to the feeding, and the lamb, from being imperfectly nourished, will only be in store condition, instead of thick fat.

No one can tell better than the wool-merchant whether the sheep have been regularly fed during the winter months or the contrary, the weight of each fleece not alone telling the tale of imperfect nourishment, but loss of substance in the fibre gives proof incontestable of parsimony or neglect. So sure is this test that even a single week's starvation will show at clipping-time, the growth of that week being thin and hairlike, the proper substance being recovered when liberal treatment was resumed. While affording a very large amount of satisfaction to the grower to hear his wool praised by the merchant as first-class, well-nourished, and well-handled, it must be in the same degree humiliating should he, on the other hand, be told that surely he must have treated his flock very badly to have the wool so wretchedly poor in fibre and so light in weight. The selling mart is thus with this class of produce, as with every other, an unfailing criterion of successful management.

Semi-starvation during the winter months will not pay; if sheep are a leading stock on a farm crops must be grown especially for their use, as well as for cattle, and their wants supplied with nearly the same regularity. Breeding ewes, which are sometimes allowed to pick up a living as they best can on very indifferent pasture, should receive a daily feed just sufficient to keep them in good health and preserve their condition. Assuming that they have had a sufficient interval, from the time the lambs were weaned until put to the ram, to recruit their strength and recover condition, much care should be exercised to preserve them strong all through the winter, so that instead of dropping weak and puny lambs, which must be the case with many of them if the dams have been badly fed, they may come to the world strong and hardy, and so get a fair start. A few turnips strewn on the pastures is all that will be required for the three months previous to lambing, the quantity being regulated according to the roughness or otherwise of the grass to which they have access. The very low price of oats at present ought to be a great inducement to owners of sheep to feed with liberality, a better food than oats being scarcely obtainable, preserving them as it does in magnificent health, and almost paying for itself, if kept up continuously, by the increased weight of wool alone. A flock of ewes, of say 100 head, will, if given three-quarters of a pound of oats each day from 1st January to 1st May, have consumed four tons of oats, costing, at present prices, about £25—a sum small in comparison to the immense benefit which the ewe and her offspring will derive from its use.

It is absolutely impossible to overestimate the value of such an amount of nutritious food both to the present and future well-doing of the flock, all other things being equal. There will, in the first place, be fewer casualties—a most important item, going a long way itself in paying the corn-bill—the fleeces will be firmer, and the lambs fat from the day of birth until that on which they leave their mother. A fat lamb four months old, nicked along the back like an aged wether, will, on the average of seasons, be worth 85s.; the same animal, if in merely store condition, scarcely bringing 20s. two months later. For

keeping up the flow of milk, turnips, corn, chaffed hay, and cake can only be regarded as auxiliaries, as there is no food so productive of milk in the ewe as grass. For the early bite nothing can come up to the young seeds; therefore every farmer should strive to have as good a breadth as possible held over, without a hoof being on it from at least the 1st of November. If he has two fields so much the better, as when the ewes with their lambs have eaten one moderately bare, they can be removed to the other, the first recovering itself and affording a fair amount of herbage by the time the second has been eaten down. The extreme usefulness of the extra food in the shape of roots or corn now shows itself by assisting the grass, making it last just double the time that it could possibly do if not supplemented with extraneous food. Lambs that have never been permitted to recede in condition or growth attain to a most remarkable size, when of the right sort, by the time they are put on the turnip break, the backs being immensely broad, the condition grand, and the fleece wondrously heavy. When abundance of keep has been provided, and the farm is well sheltered either naturally or artificially, it is of some consequence to have the lambs dropped as early as February, particularly if the whole or a portion of the flock are intended to be cleared off as fat lambs. Their owner can thus secure the highest prices of the season from being enabled to sell at a scarce time, many of the cull ewes being got rid of also at remunerative prices soon after being relieved of their lambs. Should, however, the intention be to hold over so as to finish on turnips, the month of March is quite time enough, much trouble and anxiety being saved by this arrangement. Whatever time the lambs are dropped, whether early or late, abundance of food must be provided for the ewes; so that there may not be the slightest chance of running short for even the most limited period. The cold piercing winds of early spring are sufficiently trying to the flock when well fed; but when cold and hunger are combined, the milk soon dries up, and once it does so, no amount of kindness afterwards will again bring it on. With a short supply of milk, the lambs get stunted, lose condition (and that, too, in an inconceivably short time), and cannot possibly be brought to the degree of excellence which they otherwise would have attained if not permitted to get checked in the earlier stages of their growth. We thus find that the attempt to keep a large stock over the winter without ample provision in the shape of roots, cabbages, hay, oats, or oilcake being provided for their maintenance, must inevitably result in failure, no amount of care or skilful management being able to carry them through in profitable condition. If it is desirable to keep a stock of ewes on a farm or piece of pasture-land, where there is no cultivation, it can only be successfully accomplished by running them thin on the ground, so that the grass may not get dirtied too much with their droppings, and they can have a rough bite every day in the year. If the land is of good quality, and has been laid down to grass in good heart and with good seeds, a light stock will leave a profit, when a larger number would involve a very serious loss.

On weaning the lambs, they should be removed to a field of clean grass which has been *amised* especially for this purpose; not too rich, or else it would bring on scour, and probably prove fatal to a number of them; nor yet too dry and hard, as then they could not extract nourishment sufficient to keep themselves progressing. Above all, freedom from sheep-droppings is the leading point to ensure a healthy constitution in the young creatures just at that period of their existence when they have to depend on solid food alone for a livelihood, and when there must necessarily be a very great change in the action of the digestive organs, and in the character of

the secretions. Lambs, when placed in fields which are, or have previously been, occupied by cattle, do wonderfully well, there being scarcely a casualty, unless from accident; and even although the land may be very bare of grass, they thrive surprisingly, a fact which clearly shows the necessity of providing this class of stock with a run which is clean and untainted. Towards the end of autumn, when grass begins to lose its succulence, getting watery, and devoid of nourishment, extra food should be given to them, which they will very soon learn to eat. This should consist of a little cake or corn (if the latter is crushed, so much the better), a small quantity of chaffed hay, and a few of the softer varieties of turnips, such as the Pomeranian, greystone, and green globe. It is of no use giving rapecake to lambs, or, indeed, to sheep of any age, all having a strong dislike to it. Linseed-cake they delight in; and even such a small quantity in the day as a quarter of a pound has a marked effect on their healthy development. Whether intended to be finished off for the butcher on turnips, or kept over as stores, it is well to teach them to eat thus early, and accustom them to the use of these foods, as in the event of severe weather compelling them to be altogether hand-fed for a time, many young sheep will actually die of starvation rather than touch a turnip, or at best become so attenuated before taking to the food as to become nearly valueless. It is much better policy to feed store sheep liberally in early winter, and have them strong for the spring, than to hold over the food altogether for that season.

If permitted to get very much reduced in condition, the turnips do but little good, merely running through them; whereas, when the sheep are strong, they can stand a great deal of severe weather on a moderate supply of food. Hay alone, given in racks on a sheltering part of the field, or even straw, which we have seen them eat greedily when confined in yards during a snowstorm, will bring them through a lengthened probation apparently but little the worse. It is, however, a very serious matter when such a trial overtakes them if in low condition, many having to succumb from actual inanition. That portion of the young stock intended to be finished for the butcher previous to the 1st of May must have their wants well provided for, not a meal being missed; and should they have been liberally attended to up to the period of going on the turnips, they will now both grow and fatten, attaining a great size after four months of feeding, and worth, on the average, taking one season with another, from 50s. to 70s., wool included.

Full-feeding from the period of birth has the great merit of inducing early maturity, all the animals not required for stock purposes being cleared off within the year, or, if a month or two later, not permitted to trespass on the pastures, and lessen the food of those which are coming on.

No better system was ever devised for cleaning, manuring, and consolidating the soil, and putting into the right condition for growing profitable crops of corn and grass. No one need long complain of having his land poor who is possessed of means to carry out an extensive system of turnip-growing, to be fed off the land with sheep, the objection being often brought against it that it makes the land too rich, and the after-crops are injured from the straw being too soft to stand till harvest. This fault is on the right side, and can easily be obviated, where there is such a tendency, by removing a portion of the turnips, if a heavy crop, and using a larger proportion of corn than of cake.

Very old pastures are not suited for sheep, nor land much covered by trees, the grasses of the one wanting succulence, and on the other their sourness tending greatly to retard the progress of the animals. A farm,

the greater portion of which is worked on a system of convertible husbandry, but on which is retained a piece of permanent pasture, hard and healthy, suits admirably for sheep. The green crops, so essential for finishing off, are thus at hand; and the young grasses and clovers, of which there is every season a considerable breadth, come in just at the right time, when wanted for the ewes and lambs, affording an abundant supply of milk-producing food six weeks at least before a full bite, or anything approaching to it, could be had on an old pasture-field. The beneficial influence of young grasses on sheep is fully exemplified in the great improvement effected by placing them on the stubbles to pick up what little grass they can get on the removal of the corn. Not only is condition improved, but the health of such members of the flock as have been injured by scour is thoroughly re-established.

In making arrangements for a supply of food throughout the year, it should never be omitted to have a field or two laid down without a crop, with a good selection of grasses, clovers, and a few pounds of rapeseed to the statute acre. This may extend to ten, twenty, thirty, or more acres, according to the extent of the farm and size of the flock. As a source of food of the very best kind, both as regards quantity and quality, such a piece of grass stands second in importance only to a large breadth of turnips, and when it once has been introduced, and given a fair trial, it will seldom ever be omitted. As we have already seen, the turnip is both useful and profitable in enabling the farmer to get rid of each season's young stock within the year, without trespassing on the grass reserved for those which are coming on. A piece of grass laid down in the manner we have described serves a similar and equally useful purpose by giving an opportunity of finishing off all old and cast stock, making them up in first-rate condition for the butcher, without trespassing on the turnips, permitting them to be held over for the sole use of the store and feeding stock.

The field chosen for this purpose should be in as good heart as possible, as the richer it is the better will the grasses succeed, and the better will it answer the purpose for which it is intended. Sown as early in April as the character of the season will permit the necessary preliminary operations to be performed, grasses will be sufficiently forward by the end of August to permit of being pastured, and, assuming that the summer has been a favourable one for their growth, it is really astonishing what a vast amount of valuable sheep food will be available on each acre. If the rape is rank and strong, the animals may neglect it, roaming over the field, and picking out the choicest morsels; this, however, can easily be obviated by netting them in the same way as is done on the turnip field, when they will eat the enclosed square as evenly as if it had been mown with a scythe. From four to eight sheep to the statute acre, according to size and condition when laid on, will be fully finished, and the field still left rough of grass to be held over for the ewes and lambs in spring. By no other mode of feeding or kind of food can old cast ewes be got rid of so easily as by finishing them on such grass as this; no condimental or artificial food of any kind is required, old ewes of a good breed being cleared out after a couple of months' feeding on the produce of the field alone at 80 lbs. a quarter, and choke-full of inside fat.

Our experience and opinions on sheep-farming having now been pretty fully detailed, we close by giving it as our firm conviction that full profits can only be realised on those farms which are worked on a mixed course of husbandry, the supply of food for every season being so great as to feed twice the number that could otherwise be kept, and the stock being cleared off at an early age gives both a quick return and a large profit. Much depends on the breed. Crosses we have found to do best,

that between the Leicester ram and Shropshire Down ewe being scarcely excelled by any. The latter breed of sheep we consider one of the most valuable at present cultivated, and which it is impossible to overestimate; its money-making capabilities placing it in the very highest order of merit. Too much care cannot be exercised in

the management of a valuable and highly-bred flock with regard to their health as well as their feeding, disease once introduced too frequently committing sad havoc before it can be expelled, the intense annoyance consequent on its presence being nearly as great a punishment to the flockmaster as is the pecuniary loss.

WHEAT AND BARLEY GROWING ON THE COTSWOLDS.

At the last meeting of the Kingscote Association, Mr. BURNETT said: We had lately a long account of what may be called new systems of wheat cultivation, and we often hear and read of people at a distance growing double the quantity of wheat and barley they did a few years ago, either by using steam cultivation, or by some other new system. I would not say a word against those gentlemen who have given much of their time and exerted themselves to the utmost of their ability for the advancement of agriculture, which is of the utmost importance to all—and owing to our being situated on one of the highest ranges of the Cotswold Hills, where the soil is light and near the rock, we can only feel an interest in hearing that man is succeeding in cultivating the land he occupies; but we are not to be discouraged in the position we are placed in. No one will doubt that a much larger quantity of wheat and barley is produced now per acre than was thirty years ago. I am of the opinion that this is not done by any new system, but by an improvement of the old—such as in the time of planting, using drills, instead of sowing, cultivating, harrowing, and rolling with improved implements, and last, but not least, having the land in what is termed a higher state of cultivation through the application of richer manures. All this will be readily admitted, as it is that which every real practical man knows; but the object of our meeting is to gain information, that we may be worthy of the position we hold towards the nation at large, and also towards those with whom we are more intimately connected. The first question is, can the present system of wheat cultivation in this neighbourhood be changed so as to yield a better remuneration without injury to the following crops and the farmer? Steam cultivation is one of the great improvements of the day on heavy lands, but where we can plough an acre per day with a pair of horses, taking all into consideration, it will not pay. Deep cultivation has been tried in this neighbourhood, and failed. The system of using the farmyard manure for the wheat is good on heavy land, where the farmer is not so dependent on the root crop as he is on the hills; and on what might be termed light land. I have heard it spoken highly of, but having had no experience will not hazard an opinion as to the result in this neighbourhood. Next, as regards top-dressing with artificial manures in the spring. Many advocate this practice, although I doubt whether there are as many in this neighbourhood as there were ten years ago; where the old system is practised, the cupboard of the wheat plant is supplied in the growth of roots (the greater part fed on the ground, and the rest given by the two years' ley). This is admitted to be a good system, but many tell us to just add a top-dressing in the spring, and the results will be wonderful. In 1860-61, and '62 I tried this system, and with similar results. The results of 1862 I will show you.

1862.—KINGSCOTE FARM EXPERIMENTS.

TOP-DRESSING WHEAT.

Name of Manure applied.	Produce of one year.	Wheat.		At 6s. per Bushel.		Loss of Manure		Balance.
		Bush.	Lbs.	£ s. d.	£ s. d.	£ s. d.	£ s. d.	
Proctor's Wheat a Manure	36½	60		11 11 1	2 0 0		9 11 0	
b Guano	36½	60		10 19 0	2 0 0		8 19 0	
c Nitrate of Soda	37½	58½		11 5 0	2 0 0		9 16 0	
d Soot	36	60		11 8 0	1 12 0		9 16 0	
e No Manure	33	60½		9 13 0			9 13 0	

a Produced a larger quantity of straw than 2, 4, and 5, but inferior sample.

b 2 and 4, similar quantity of straw and sample.

c Largest quantity of straw, and worst sample.

d Least, but much the best sample.

The other evening, when we heard the subject of top-dressing

discussed, several were of the opinion that it was advisable where there is a thin, weak plant. I quite agree with them, and could bring many proofs in support of it; but I will only mention one supplied by a much better authority than myself—the late E. Drew. An application of 4 cwt. of Messrs. Proctor's wheat manure per acre, at a cost of 32s., to a thin plant on a light soil, calculating the wheat at 6s. per bushel, and the straw at 20s. per ton, left a loss of 4s. 8d. Guano, under precisely similar circumstances, gave a profit of £1 4s. 9d., and nitrate of soda £3 4s. 5d. The straw and corn, however, from the wheat manure were of a better quality than from either of the others. What I have said only applies to wheats planted on what we call old seeds. A quantity of autumn wheat is planted after roots, and with better results than spring wheat, even as late as the middle of next month: the cultivation is very similar to the early planted. I would only say, where the land has been ploughed deep for the roots, the lighter it is done the better for the wheat; or, if it is to be planted immediately after the roots are off, the cultivator going twice through it will answer better than ploughing. Spring wheat will do well with the same cultivation as barley. Wheat cultivation on heavy soils has been, and can be, much more improved by steam power. The rotation is also very different. One year's ley and beans often take the place of roots, and on very heavy soils the system of bare fallow is practised with success. Ploughing up the seeds early, and working the land with the cultivator and other implements before planting the wheat, is of very great importance. So much having been said at our late meeting respecting the time of planting and the quantity of seed per acre, I think it better to leave this matter until we hear the opinion of the meeting. Barley cultivation is a very important subject, especially in this neighbourhood, owing to the suitability of the soil for growing good barley, as there is a wide difference between the price of a really good sample and an inferior one, and barleys are not so good as they were years ago. Barley requires a seed-bed just the opposite to autumn wheat. A stale furrow and heavy soil are most suitable for the latter, and a fresh furrow and light soil for the former; or, as the old saying has it, "Barley in the dust, and wheat in the dirt." As a rule, we find the early-planted barley the best sample; but I am of opinion that this has more to do with the condition of the soil than with the time of sowing. We all know that it is an easier matter to get a good seed-bed on land that has been fed off early, and raftered immediately after feeding-off—a plan with which I hold. But when a heavy crop of swedes has been fed off through the months of February and March, especially if there has been a quantity of rain and snow, it is almost impossible to get such a seed-bed as one would like; neither is the crop a satisfactory one. It is an easier matter to point out the cause of the bad crops and quality of the barley than to find a remedy, without making such an alteration in the rotation of cropping as, I fear, would not be to the improvement of the land, nor advantageous to the farmer.

After a discussion, it was resolved, "That, on the high lands and light soils of the Cotswold hills, wheat is best grown after a two years' ley, ploughed up in the end of July and through the month of August, then well rolled down, so that, in harrowing and preparing the same for the drill, care should be taken not to break up the bottom of the furrow. That drilling should not commence before the third week in September, and be finished by the middle of October. That it is not advisable to plant more than two bushels of seed per acre; and that only where the plant is thin, weak, or sickly-looking in the spring, it is advisable to top-dress with some kind of artificial manure, say, nitrate of soda, at the rate of 1½ cwt. per acre, or better, the same money value of soot, in the months of March or April."

THE WINFRITH FARMERS' CLUB.

THE VALUE OF FARMERS' CLUBS.

At the dinner, Mr. J. J. BATES, the President, in the chair, Mr. ROBERT DAMEN said the Lord-Lieutenant and Magistracy of the county were a body of exceedingly able men, who took a great deal of trouble and pains in the discharge of their arduous but honorary duties. Their decisions were seldom such as could be found fault with—certainly not oftener than the paid magistracy.

The CHAIRMAN read over the list of prizes awarded for the best root crops grown during the past year, as follows: General root crop—First, £5, Mr. T. H. Saunders, of Watercombe; second, £3 10s., Mr. J. H. Calcrafft, Rempstone House; third, £2, Mr. R. White, Barton. Best ten acres of swedes—First, £3 10s., Mr. J. Scutt, Bere Regis; second, £1, Mr. T. Randall, West Lalworth. Best five acres of swedes—£1 10s., Mr. W. C. Lacey, Bestwall House, Wareham. Best ten acres of turnips—£1 10s., Mr. J. Reader, Winfrith. Best five acres ditto—£1, Mr. Randall. Best ten acres of mangold wurtsel, £2 10s., Mr. W. C. Lacey; five acres ditto, £1 10s., Mr. Sly, Bmdon Mills; two acres ditto, £1, Mr. C. Besant, Shetterton Farm, Bere Regis.

Mr. T. H. SAUNDERS responded for "The Successful Exhibitor." During the time he had been connected with the club he had taken a great many first prizes, and it was again his lot to return thanks for the way in which they had received the toast. He had always studied to improve the quality of the root crops, not merely for the sake of winning prizes, but to secure a good kind of keep for his stock during the winter. He had sworn what he considered was best for feeding purposes, and in this practice he had found it most advantageous to grow all his roots after green crops; he kept no fallow land at all. He must say that, being the winner of the prize for the general root crop, he was somewhat disappointed in not being awarded the prize for the best ten acres of mangolds; but the judges said, though his crop was exceedingly fine, he could not enter for both the prizes. If, therefore, the gentleman who had gained that prize would hand him over half of it he would be perfectly satisfied. Although he did not gain the prize he showed his crop of mangold to the judges, and he would leave it to them to say whether or not he was entitled to half the money. Some people had said that in growing a good root crop he had gone a little too far, and that he had kept more stock than he was justified in doing; but if this was true he considered his landlord had shared the benefit as well as himself.

Mr. J. H. CALCRAFT, who was also called upon, quite agreed with Mr. Saunders that it was desirable to grow a good root crop, but there was a great difference between the land which it was his lot to farm and that around the neighbourhood of Watercombe. Last year the judges awarded him the prize for a good lot of turnips—to look at; but when fed off his sheep did not improve much upon them, and, if the sheep were the judges, they would have returned a very different verdict. But it was an exceptional season, and no doubt these excellent gentlemen who were appointed to view the crops decided in his favour from seeing the turnips in pretty even rows with very few weeds amongst them. His turnips had size in them, but he thought very little nutritive qualities, thus showing that roots grown in bad land would not produce the good effect upon stock that is to be gained by feeding on roots grown in good land. The same rule applied to oats. He once had a fine, upstanding, healthy piece of oats, which produced 30lb. a bushel, but his horses were starving. He observed to his carter that the horses did not appear well, and that their coats did not look so well as they ought to do, thus proving that, although the oats were good in weight, they lacked the properties of nutriment. Thus it was to the advantage of the farmer to improve the quality of his land by every means in his power, and he was proud to appear at this meeting under the shadow of his excellent and experienced friend Mr. Saunders.

Mr. W. C. SPOONER, living as he did at a considerable dis-

tance, was, however, very happy to contribute his mite so as to give a little stimulus to agriculture, more especially in the cultivation of roots. He congratulated the club upon the steady progress it was making, and the sound valuable information it elicited in the interest of agriculture. This he attributed in a great measure to the fact that the members embodied the representation of the various branches of practical agriculture, and consequently more reliance was placed upon the opinions that were adduced at the meetings held for discussion. It was no small matter to have held their own for 25 years, in spite of the opposition which men formerly evinced against meetings for the discussion of agricultural matters, or any other subject in which they were interested. But of late years greater opposition, though of a friendly character, had sprung up, for since the establishment of this club others had been formed at Milborne, Dorchester, Blandford, and elsewhere, while chambers of agriculture had also been organised, each and all of which had their attractions. These chambers of agriculture met in different parts of the country from time to time, and there was sometimes a greater degree of novelty in them than they could boast of in their farmers' clubs. But this he would say, if the tendency of chambers of agriculture was to destroy or to supersede farmers' clubs, they would do more harm than good. There were plenty of subjects to be taken up by both, but it was the province of farmers' clubs especially to deal with matters of practical agriculture. He observed that the next meeting of the Dorset Chamber of Agriculture was to be held on a market-day, and of this plan he must express his disapproval. When gentlemen travelled a considerable distance to attend the corn market, was it not too hard to ask them and their customers to divide the few hours at their disposal, and which should be devoted to business alone, to attend their meetings? If the same system were adopted in other counties as in Dorsetshire, chambers of agriculture must in time fall to the ground, as farmers and those most interested could not devote so much of the best of their time to attend their meetings. He trusted the Winfrith Farmers' Club would prosper for many years to come, and he could not conclude without passing one tribute of acknowledgment to the able and constant exertions of his friend Mr. Reader, who was formerly their secretary. For many years he had well and ably performed his duty, and when they in other parts of the country heard of the distressing illness with which he was afflicted, and which forced him to relinquish the post he had so admirably filled, sympathy for that excellent officer was by no means confined to this club. They in other counties were ready to send up their earnest prayers that Providence might still spare his life, that medical skill might prove successful in his case, and that he might be restored to his former energy and strength to labour for the club, and to see the continued success which he so long laboured to accomplish.

Mr. J. H. CALCRAFT, in proposing "Success to the Winfrith Farmers' Club," said those who remembered this part of the county many years ago could not fail to bear testimony to the great change for the better which had taken place in the general system of agriculture and the state of the crops throughout the whole district. How much the club had had to do with this improvement it was impossible strictly to say; but, as Mr. Spooner had said, it had been in existence for the last quarter of a century, and, as the general root crops had very materially increased, it was only fair to assume that the operations of the club had had something to do with this good result.

Mr. GROVES responded for the judges. One gentleman over whose ground he rode, produced a bottle of port 50 years old, though he would have preferred it rather more fruity. Another gentleman drove him about in his high carriage, and, although there was some hard work attached to the office of judge, the labour was interspersed with many little pleasantries. On some of the land over which he travelled

there was a swarm of "villainous game," and he regretted to see so many hares and rabbits perpetrating such damage among the crops. He suggested that in future judges should be allowed to carry a gun a-piece, so as to "combine pleasure with business," as it was a shame for gentlemen to allow such a lot of trash to infest the farmers' crops. The crops generally, he said, were excellent, and he never saw land better managed than in this district. It was almost as good a specimen of farming as they witnessed in the neighbourhood of Milborne.

Mr. W. MARK proposed "Success to the neighbouring Farmers' Clubs," and spoke of the vast amount of good they had effected amongst the agricultural interest. He was glad to find there were so many well organised Farmers' Clubs in the county, for, recollecting that "union is strength," it was only by uniting their efforts that any real benefit could be accomplished. For his own part he had derived much profit from the practical discussions on agricultural matters to which he had listened, and he trusted that the clubs may continue to receive the support they so eminently deserved.

Mr. T. H. SAUNDERS, the Vice-chairman, said they well knew it cost £100 a-year more to keep a farm in good order than in middling condition; besides he could speak for himself as to the extra expenses on his own farm, which had increased £180 a-year on labour and rates within the last ten years—a heavy item which neither landlord nor tenant had any control over, but it was a burden for a tenant farmer to bear, and it ought to be looked upon by the landlord as a rise of rent to that amount, which it virtually amounted to. What he called the fair rental of a farm was what was left after all the incidental expenses were paid and the tenant had received the fair interest on the working capital he employed. He did not believe many of them realized half that amount. However, he should be satisfied if it stopped here; but no—after they had worked hard in the endeavour, as they thought, to help their landlords, what was the result? As soon as they had their farms in good order, at a very considerable outlay of their own capital, many of their landlords increased the rents. He did not mean all; he mentioned no names, nor did he allude to any individual in particular, much less landlords members of this club; but it seemed to have become the order of the day—except with a few whom he called patterns for Dorsetshire landlords, who had tenants from one generation to another, and who never thought of raising their rents (except when deaths occurred) while farms were kept in

good order—that at the end of the year, or the expiration of the lease, the landlords said to them, "I don't want to get rid of you, but I think your farm is in good condition, and I therefore want a little more money." Then a surveyor was sent over the farms, who knew the rent must be increased, be it ever so high before, and when the tenant had expended a large amount of capital to improve it, without suspicion of being so unfairly taxed with additional rental. On the other hand, if they had only used the natural power of the soil previously, they might have done better for their families, and the rents would not have been advanced. Therefore, he said, where was the advantage in farmers' clubs endeavouring to get the land in the best possible order to help their landlords and at the same time to ruin their own families? He considered they ought to be satisfied with a good enterprising tenant instead of raising him £50 a-year, and as soon as he is obliged to quit, to lower it £100 a-year again before he can find a middling tenant to take it, which by experience they knew was oftentimes the case. The principle reminded him of the man in the fable who had the "goose that laid the golden egg," and killed it in order to have all the others at once. He admitted the legal right of the landowner to let his farm to any person who chose to give the most money for it; but he did not call it justice to any old tenant who had spent his own capital and was obliged to leave it in the land for another's benefit. He had always advocated good farming in this room, but he now saw his error; but as a practical man of experience he could not any longer do so. He could not wear two faces under one hat, and it was on this account that he had sent in his resignation. It had often been talked about privately that it had been the case as he had now stated, but as they lived in a free country, he, as an Englishman ought to do, spoke openly on the matter, he hoped without offence to any one. He had only expressed what he believed to be the truth. They as farmers had not been rewarded as they expected when they formed this Club, and there were many ways of raising their rents besides in money payments—some in covenants, and, worst of all, to have their crops eaten up by rabbits and hares. They had stood a long trial and had unexpectedly lost the verdict. Therefore he bade them farewell, hoping that landlords who had any respect for their tenants would never think of increasing their rents, with wheat at £10 or £11 a load, and this was the great barrier in the way of the improvement of English agriculture.

THE PROFITABLE TREATMENT OF WOODS AND WASTES.

At a meeting of the Botley and South Hants Farmers' Club, Mr. BLUNDELL said: I am bound to say that I have for a number of years considered that the question now for discussion is one which has been comparatively neglected and overlooked amongst the more exciting subjects, such as steam cultivation, and others, which have for some time past commanded a large share of the public attention. It, at the same time, seems to me, looking at the position of the agricultural interest generally, that our subject, if practically considered in all its bearings, is one which, if well ventilated, will show how desirable it is for the interest of landowners, occupiers, labourers, and the public generally, that the capabilities of the woodlands and wastes of this country should be better understood and appreciated, for whether we look to the production of timber of various kinds, or whether we look to the produce of corn and cattle, it is a question of the deepest importance to the welfare of the people of this country, inasmuch that the nearer approach we can make to the universal appropriation of the whole surface of the land for productive purposes, just so much nearer do we advance towards being able to support our own population without foreign importations, and I trust that before the conclusion of this discussion, it will be shown how large and valuable a property in the "woods and wastes" has been neglected, and how extensive and important are the resources existing and ready to hand if profitably managed by the judicious employment of labour and capital thereon. It is rather singular that only one subject at all like the present one was ever taken up by this club during the past twenty-five

years, which was "The removal of hedgerows and hedgerow timber." That, however, must be viewed as a very narrow subject as compared to ours on the card. This subject seems naturally to be divided into two sections. I therefore propose to consider—first, the treatment of woodlands, and, secondly, the treatment of wastes and common lands. Let us, therefore, in reference to the woodlands, inquire how profitable usage of the land can be obtained, either by retaining it as coppice, or by conversion into arable or pasture land; and I propose to bring to your notice, the better to illustrate our subject, a certain number of woods and plantations, with the view of showing by calculation, whether they are advantageously to be retained as woods or otherwise, and in doing this I shall select some pieces with which I am somewhat acquainted, and which, at various times, have come under my notice during my business engagements, in different parts of the country. No. 1 is a piece of woodland, about 20 acres, the soil being a good loam on chalk. There is no timber, but it is well stocked with ash and hazel underwood, used for hop poles, hurdle making, &c. The produce is usually cut at twelve years' growth, and is worth £16 per acre; the adjoining land is arable, and is worth to rent 28s. per acre, thus showing that but little if any advantage could be derived by bringing this woodland into cultivation, except it were for the improvement or the better laying out the adjoining fields, which latter points must always be viewed as important matter. No. 2 is a precipitous piece of woodland, of about 35 acres, in a western county, on the stone formation, with very little timber, but a good plant of under-

wood, chiefly of oak stems, which grow very quickly in their moist climate, and is usually cut at eighteen years' growth, the time for cutting the largest stems being deferred until April and May, the wood being commonly stripped for the sake of the bark. In this particular wood the land is so steep that the men employed in cutting can scarcely keep their footing. This wood, after being barked, is used for making hurdles and other purposes, and yields a return which could not be surpassed by any other known usage, the land being too hilly and too near the naked stone for cultivating or planting. No. 3 is a level piece of woodland, in a southern county, and is situated a long distance from chalk or marl, contains about 16 acres, is surrounded on three sides by arable land, the value of which to rent is 30s. per acre. The woodland is of the same description of soil, which is strong and gravelly, but does not require draining. There is a good plant of timber, principally oak, about 160 trees per acre, a large proportion having been left from stemmers. It is only those which have proceeded direct from the acorn that make any perceptible growth. The underwood is very rough and bushy, not worth more than 40s. per acre at 10 years' growth. These trees do not meet in measurement at more than 4 feet of timber, and do not increase annually more than $\frac{1}{4}$ per cent. on their value. The following calculation will show the propriety and profit of taking the crop of timber and converting the land into arable:

	£	s.	d.	£	s.	d.
Expenses—Grubbing, per acre	10	0	0			
Chalking.....	4	0	0			
Outlay	14	0	0			
Interest on, at 4 per cent.				0	10	6
Value of 160 trees, 8 ft. meetings, 640ft. at 8d.	21	6	8			
Annual increased value on the same, at $\frac{1}{4}$ per cent.				0	6	6
Value of underwood	2	0	0			
	23	6	8			
Annual value of the underwood				0	4	0
Total annual value of woodland in present state ...	1	1	0			
Value of land to rent per acre after grubbing, being tithe free				1	4	0
Gain by interest on value of timber and underwood sold off, £23 6s. 8d., at 4 per cent.				0	18	6
Value after grubbing	2	2	6			
Ditto before ditto, deduct	1	1	0			
Actual advantage of converting into arable	1	1	6			

No. 4 is a piece of woodland, of about 11 acres, on the same description of soil as No. 3. The timber is for the most part oak, about 100 trees to the acre, at 6 ft. meetings. The underwood is of the same inferior description and value as No. 3, say 4s. per acre per annum. This coppice of timber was much more growing than No. 3, and would increase in value about 3 per cent. per annum. This wood is introduced to notice for the purpose of showing the advantage or otherwise of a plan which obtains in some parts of England, viz., stubbing or grubbing the underwood, with the view of obtaining pasture. In this coppice, however, the grubbing between the timber which is left has cost £6 per acre. The feed of this land is of the poorest description, and not worth more than 7s. per acre rent. The timber, I estimate, instead of paying 3 per cent. in its growth, is so much injured by letting in the wind that it will not now increase at the rate of more than $\frac{1}{4}$ per cent. It will, therefore, be readily seen that this coppice has not been properly treated. Had it, however, been brought into cultivation it would have paid as well as No. 3, and, being surrounded by arable land, would have greatly improved the adjoining fields, especially as the boundaries are of an irregular and zigzag description. No. 5 is a good piece of woodland, about 24 acres, in a southern county; the land is level, consisting of a fine hazel loam, surrounded entirely by arable fields of the like soil, and worth to rent 35s. per acre. There are about eighty trees to the acre of 8 ft. meetings, and all oak. The underwood is worth £2 per

acre, at ten years' growth. These trees have been nearly all let up together, and they should stand or fall together. I, however, estimate that they annually increase in value about 3 per cent. only. This land under cultivation would be worth 40s. per acre rent, being tithe free. In this case also we must not lose sight of the immense benefit to adjoining lands by the removal of this wood. Let us now calculate the advantage of bringing this land into cultivation:

	£	s.	d.	£	s.	d.
Expenses—Grubbing per acre	10	0	0			
Chalking.....	4	0	0			
Outlay	14	0	0			
Interest on, at 4 per cent.				0	10	6
Value of 80 trees, 8 ft. meeting, 640 ft. at 1s. 3d.	40	0	0			
Annual increased value on the same, at 3 per cent.				1	4	0
Value of underwood	4	0	0			
	24	0	0			
Annual value of the underwood				0	8	0
Total annual value of the woodland in its present state	2	8	6			
Value of land to rent per acre after grubbing, being tithe free				2	0	0
Gain by interest on value of timber and underwood sold off, £24, at 4 per cent.				1	15	2
Value after grubbing	3	15	2			
Ditto before ditto, deduct	2	8	6			
Actual advantage by converting into arable	1	13	8			

No. 6 is a poor soil, being a mixture of sand and gravel, with a blue pebble in it. This wood is also in a southern county, extends over about thirty-four acres, and is bounded on two sides by good roads. There is no underwood, but ferns grow strong. Some fifty years ago it appears to have been planted in an irregular and careless way with Scotch fir, some of which having been cut at intervals, there are now only a few trees left, probably about forty to the acre. They are now quite fit to cut, and it is easy to see how little gain has been or can be derived from timber left in the manner described, and it should be borne in mind that although this land is too poor for corn growing, yet it is such as would be profitable under a course of cropping for timber upon a plan which I intend presently to explain. In the immediate neighbourhood of this woodland there are large tracts of land, belonging to different proprietors, exhibiting precisely the same state of neglect. No. 7 is a poor hillside on a chalk soil, and contains about 17 acres. It is well planted with beech wood, there being about 160 trees to the acre, and of course no underwood, as the beech, like the uper tree, suffers nothing to exist under it. This timber is nearly arrived at maturity—that is, it would pay better to cut than remain, because the interest of money would pay double that of the growth of timber, and under the plan to be offered to your notice the land may be planted with fir, and continue to be more remunerative. No. 8 is a plantation of Scotch fir on some of the poorest soil in Hampshire, with a regular plant of about 200 trees to the acre. This plantation is deteriorating every year; the trees were planted about fifty-five years ago, therefore the crop should be taken for what it will fetch, when the land may be planted with superior kinds of fir to be hereafter alluded to; and I would here remark that it would be just as reasonable to allow our crops of corn to stand in the field for months after they were ripe as it is to allow plantations like this to remain when they may be sold to the best advantage and the land cleared for another crop. Having endeavoured to show that wherever the land is adapted for arable or pasture in the majority of cases the most profitable treatment is to cut the timber and invest the money to grub and cultivate the land, except in cases where the land is too poor for corn or grass produce; I will now proceed to state several plans or systems of planting fir, pines, cedars, &c. for profit. First is a method of planting larch fir for a quick and profitable return. The land should be trenched or steam cultivated not less than eighteen inches in depth; the use of fresh, strong

manure should be avoided, although good vegetable mould may be applied with advantage on very poor and stony soils. The plants should not be too large—say about 24in. to 30in. high; and if they have been grown and previously transplanted on poor soil so much the better, if they are healthy, clean grown and well rooted. The first two years after planting the land should be kept clean by hand-hoeing. Particular attention should be paid during their growth by the removal of diseased or decayed plants, and as soon as the poles are marketable (which they will be by taking the best at the end of eleven years) commence by thinning and selling, looking only for a quick return. I believe a great mistake is made by many, who allow the plantation to go on unnoticed until the plants are neither fit for one purpose or the other—not large enough for sawing into rails, pales, &c., yet having passed the size called poles. It often happens also that the plants are set at too great a distance from each other; the consequence is they do not grow so fast, neither do they make such handsome poles. When planted close they protect each other, the winds take less hold of them, and they gather more moisture from the atmosphere in the summer months. They cover the land quicker, keeping in check both grass and weeds. Again, instead of growing boughs, the growth centres in the poles, which come earlier for use in consequence. In following the above plan the plants should be set at thirty-six inches by thirty inches apart. I will now furnish a statement of the cost of planting, and also the mode of taking and the value of the crops per acre:—

Expenses—Trenching 18 inches deep, at 1s. 9d.			
per rod	£14	0	0
5,250 plants, at 25s. per thousand ...	6	11	3
Planting by spade	2	10	9
Hoeing... ..	1	0	0
	<hr/>		
	£24	2	0
Interest on the outlay of £24 2s., at			
4 per cent. for sixteen years ...	15	9	4
Failures allowed, at 10 per cent. ...	7	15	0
	<hr/>		
Total expenses of plantation...	£47	6	4
Commence cutting, taking the best at the—			
11th year cut 600 poles, at 3d. each ...	£7	10	0
12th year do. do. ...	7	10	0
13th year do. do. ...	7	10	0
14th year do. do. ...	7	10	0
16th year cut the remaining 2,850 poles, at 4d. each ...	47	10	0
	<hr/>		
Value	£77	10	0
Cost	47	6	4
	<hr/>		
Profit	£30	3	8
Annual profit, 38s. per acre.			

As, however, the plan of quick returns, as just stated, by the growth of only larch fir requires a great deal of constant attention, some parties may object to it for that reason or others. I will, therefore, allude to a plan whereby a less number of plants may be set, and take the crop at the end of twenty-five years, and in this case, if required, rows of sweet-chestnut, hazel, ash, &c., may be planted, with the view of remaining for the growth of underwood after the crop of poles has been sold off. Planting is advised in the following way—larch fir plants at intervals of three feet and six feet alternately, and at three feet apart in the lines, the six feet space being planted with underwood plants at three feet apart. Then, at some intermediate time, each line of poles at three feet apart may be cut and sold, as also half the poles in the remaining line, thus leaving the lines of furs standing for the main crop at six feet apart each way, and the underwood plants will be found standing also at the same distance. According to this plan there would be left at the end of twenty-five years about six poles to the rod, which at 1s. each, would give £48 per acre, being a large return, in addition to the valuable plant of underwood left on the land. There is yet another system of planting fir and pines or cedars to which I wish to call attention, more particularly where it is intended that large trees be the object to be attained. In such case I should plant three sorts in alternate rows, or, rather, at right angles. The sorts

I recommend are the cedrus deodara, the Douglas fir, and the common larch fir. The first row to be cedrus deodara, with larch alternately at equal distances; the second line all larch; the third line Douglas fir with larch alternately, at the same distance apart; and the fourth line with all larch plants. Then proceed with cedrus deodara and larch as for the first row, and so on throughout the plantation, the distance recommended for the plants being about six feet apart each way. In thinning out the larch they may remain until worth about 1s. each, which they would be at about eighteen years' growth, thus leaving the cedrus deodara and the Douglas fir for the main crop, these sorts being calculated to grow to an immense size and height if properly set out at the right distance, which distance, as proposed above, would be twelve feet from plant to plant each way. The cedrus deodara and the Douglas fir, as I believe, have not been cultivated for profit in this country, but only used for ornamental purposes. In the latter respect they are comparatively well known, and I am only justified in introducing them to your notice as profitable timber producers through the high encomiums passed on them in a work called "Pinacea," which is the soundest practical treatise on fir and pine culture now extant. I, therefore, to justify my recommendation for planting, quote from this work the writer's opinions on their growth in their native habitats, and his experience as their adaptation to our soils and climate in England for timber growing purposes, and, relying on these statements, we are justified in assuming that their growth here would be profitable, not only as regards the bulk of produce in timber, but its utility for all ordinary purposes. In order, however, to obtain plants of these cedars and pines, they must be raised from seed, as they cannot now be obtained from the nurseries except at a very high charge, they being grown for ornamental purposes only; and in growing plants for own use they should be grown in soil and climate similar to that where they are to be planted. In conclusion of the first part of our subject I wish to make a few general observations. Trees for timber in woodlands should never be lopped or shrouded, nor should trees be ever left within twenty feet of the boundary fence joining arable lands. In making plantations upon land which is too wet, instead of underdraining, as for corn land, it is best done by opening trenches from two to three feet in depth, and from twenty feet to thirty feet apart, according to soil, as pipe tile draining in woodlands would soon become choked and useless. Steam cultivation I have seen successfully done in bringing heath land into cultivation, at a cost of about 30s. per acre. It is also recommended with sufficient power as the means of grubbing ordinary coppice land, including the lifting of tree stools, at a cost of from £3 10s. to £5 3s. an acre. In the foregoing pieces of woodland noticed, I have made no statement of draining such lands as require it, because it is only to add the cost of draining to the other expenses, and charge interest upon, which would still leave a large profit. In entering upon the second part of the subject, "The profitable treatment of wastes," there is indeed a wide field before us, and the subject seems so extensive that I almost wish it had been kept for a future meeting and discussion. To proceed, I beg to observe that nothing has contributed so much to the improvement and bringing into cultivation the waste land and commons as the late Enclosure Act, and I know of no Act of Parliament in this country which ever answered better for the purposes for which it was intended, and it is to be doubted whether any part of England has benefited more by it than the district of this club. If we look back twenty years we see that during that period a large extent of waste land has been enclosed, and where capital has been expended and intelligence has been displayed in breaking and cultivating, the land generally has been remunerative. In naming a few of the most important enclosures, many members will recognise their own property, for many present have been participants in the allotments as well as myself. We have seen Curdridge Common, Botley Common, Bursledon Common, Waltham Chase, Strood Wood, Titchfield Common, Netley Common, and others enclosed, all of which are now, or might be made, productive, the largest portion for ordinary agricultural purposes. Some of the poorest portions, the sand and gravel soils, are, however, best adapted for plantations—for the growth of timber only. The waste lands, within our recollection only affording a very scanty herbage for cattle or turbarry for the cottagers, are now for the most part, through the enterprise of individuals, made productive of corn and cattle in abundance; and one of

the most striking features in the case is that, generally speaking, very few persons entertained the opinion that large portions of the land could be made productive. There are not wanting instances, where the land has been properly handled, which have completely falsified the general opinion, and the example of a few is now operating on the minds of the many, and the work of breaking up and cultivating goes on with accelerated speed. No doubt a considerable portion of the land not broken at present is because the owners believe it will not pay for the outlay, and this is the case, no doubt, in some instances where the land is now under cultivation. It is too poor for corn or grass production, but I venture the opinion that there is no part of any of these enclosures but may be made profitable under a system of planting designated by the modes of planting firs or pines before alluded to. The great merit, however, of these extensive enclosures consists in the fact that wherever manorial rights or individual and private rights existed in connection with these wastes, it has resulted in a transformation of the face of the country truly marvellous in comparison with its former state. I shall not take up your time by going into the best methods of grubbing and cultivating new land, for the results of enclosing land in this neighbourhood show that it is generally well understood. Although I have said much in favour of private and individual enterprise, what am I to say when the truth must be told of the wastes, forests, and commons, called Crown Lands, in this country? Suppose a foreign agriculturist on visiting this country to land at Portland and take train at Weymouth, proceeding by way of Southampton to the metropolis (and it required but little stretch of imagination to anticipate the conversation with a fellow-traveller), he would very naturally exclaim "Can this be England? a country whose boast is its agriculture!" 'Tis true he catches a view of a few districts of well-cultivated land; but so large a portion being waste, or forest land, he would be struck with astonishment, more particularly when it is stated that the wild and barren districts mostly belong to the Queen, and are in the hands of the Government, whose Commissioners of Woods and Forests have the management. I am sure you will agree with me that it is a matter of severe reproach to this country that the Crown lands not required for the growth of timber should fail in producing a large revenue and a large increase of employment and food for the population. My ideas as to how this might be done are as follows:—Take the New Forest, for example, although this forms only a portion of the Crown lands, and see how it might be turned to profitable account. About fifteen years ago, if I am rightly informed, an Act was passed which authorised further enclosures for planting trees, and other matters; after which a commission was appointed for defining all rights and interests of parties claiming in respect of cattle feeding, turbarry, &c., and I assume that as these rights have now been defined it would greatly facilitate further operations, because those parties having rights might now be paid the equivalent in land allotments. I would therefore suggest that the Government should proceed to dispose of the land by selling under lease for the longest term, in the following manner. There are large portions of land contiguous to estates adjoining the forest, which might be offered for sale in suitable lots, having due regard to these estates, which would sell readily; this, as the first operation, would absorb and dispose of a considerable portion of the land. There are also numerous and fine building sites in the Forest well adapted for the erection of country seats for gentlemen of property, by whom they would be readily purchased, together with some number of acres of land adjoining, especially if the timber on the land were sold with it, this timber being in most cases quite useless for navy purposes, but generally well adapted for ornament and improving the landscape. I have no doubt some of these building sites would realise long prices per acre. The sale of other parts of the land may be made by offering it for farming and other purposes. In fact there is no part of the Forest but would sell well, for it is capable of being turned to account in various ways, some as arable, some as pasture, and the very poorest is well adapted for the production of firs and pines, if properly planted. In order, however, to make the most of these sales, the land should first be intersected by good roads, and main dykes for drainage. It appears from a report made to the commissioners in the year 1854 that the New Forest contains 68,000 acres. This includes, however, large plantations of oak, which have been made from time to time by the

Crown, ostensibly for the purpose of the growth of timber for the navy. It is in consequence difficult to say what quantity of land is still in a waste and unproductive state, but it must be extensive, as the map which I now produce will show. I trust that you will agree with me that this now picture of desolation may be converted into a flourishing and productive district, yielding an enormous revenue to the Crown.

Mr. PURCHASE said larch fir and ash should be planted at a distance of 24 inches apart. He recommended the following mode of cultivating waste land, taking, as an example, one acre. Fir plants, 8,800; ash, 1,440; total, 10,240 plants, distributed thus: First row, larch; second, every alternate plant, ash; the cutting to commence at the end of the eighth year, and the whole should be cleared sixteen years after planting. The cost of trenching would be £12; plants, £12 10s.; planting, £5 10s.: making a total of £30 per acre. Then the rent of land at 10s. per acre for sixteen years would be £32; add for the cost of trenching, plants, and planting £62. The ash, forming one-ninth, he claimed the same proportion, £6 17s. 9d., from the £62, leaving £55 2s. 3d.; the interest on £30 at four per cent. for sixteen years, £19 4s.; making the total £74 6s. 3d. He would commence cutting the eighth year, when the produce would be 1,280 poles, which would realise, at 3d. each, £16. The ninth, tenth, eleventh, and twelfth years would yield 8,840 poles, which, at 3d. each, would amount to £448. The thirteenth, fourteenth, fifteenth and sixteenth years producing 1,920 poles, at 3d. each, would amount to £24. Then the 7,040 poles sold would realise £88; from this take £74 6s. 3d., the total cost, it will leave a profit £13 13s. 9d. per acre, and a plant of ash would be left on the land to go on for a future crop. Mr. Purchase observed that he had allowed eleven plants per pole, or 1,760 per acre, for losses and failures. It was a mistake in planting to place the young trees too far apart, for by placing them closer together they nursed one another. The head of the plant was the conductor of moisture.

Mr. WARNER, the chairman, agreed with Mr. Purchase that, up to a certain time, larch could not be planted too thick, but beyond that time they would destroy each other. It was like leaving turnips or other plants too thick. With oak timber the thinner it was set out the faster it grew.

Mr. Purchase recommended that the larch should be planted too feet apart each way.

Capt. MAXSE observed that he simply attended that day for the purpose of gaining a lesson in woodland growing, and had received a very valuable one from Mr. Blundell. He could most thoroughly corroborate his statement with respect to the Douglas fir, having planted some himself, which had made such progress in three years as astonished him. With respect to waste land, he had taken every possible opportunity of entering a strong protest against a system which permits so much waste land to exist as was now found in this country. There was great agitation now going on in London in favour of emigration, in which he had been asked to take part, but refused, because it seemed to him perfectly absurd to think that the solution of our pauper and criminal problem could be found in emigration whilst the waste lands of the country remained in their present state. He believed that not less than one fourth of the cultivable land of England was now out of cultivation, and that this was not confined simply to Crown lands, but included that of private individuals. Mr. Blundell had referred to the enclosure of commons which took place some years ago, and had he known this discussion was going to take place, and that Titchfield common would be referred to, he would have brought with him certain statistics relating to that common, which was allotted upon the principle of large parcels to large landowners and smaller quantities, down to a rood, to small proprietors; but of the large allotments he did not think there were more than three or four in cultivation, whereas the whole of the small parcels were being cultivated, and he thought this was sufficient to justify their asking that in the event of there being any future allotments of the kind they should be made upon the modern principle—namely, with a condition as to their cultivation. He said modern principle because in a recent grant respecting the oyster fishery in the Hamble river certain rights therein were granted to gentlemen under a new act upon condition that they used their best exertions to utilise that river and cultivate its resources. He should like to see a small tax, to

be determined by a body of scientific gentlemen, levied upon all cultivable land left out of cultivation, on the principle adopted by the United States, as he believed that would induce owners to cultivate it:

The CHAIRMAN: You can rate it at what it is capable of producing.

Capt. MAXSE: Just so. His land on Titchfield Common paid him very well. He supposed that it cost him about £12 per acre to get it into cultivation, but he at once received 30s. per acre, putting it at the smallest rent, and if that did not pay him he knew not what would. But, apart from this, he held very strongly that the remedy for pauperism was the application of waste labour to waste land.

Mr. SPOONER said any one living in the neighbourhood of the New Forest must be impressed with the fact that this subject required ventilation—that it could not be right for a country like England to be continually sending its population to other lands, and at the same time to allow so many thousands of acres to remain unproductive, more especially when there was no longer a plea for preserving it to grow timber for the navy. The subject divided itself into two parts—one, what kind of land would pay for cultivation, and what the value of the land should be that it might pay; the other part related to Crown lands. He thought that cold clay lands now kept on estates for the growth of underwood would not pay for cultivation nor to break up for pastures, but there were no doubt thousands of acres in the Forest which could be made to yield a greater return than by keeping them in their present state, and, after passing through the Forest thousands of times he could not help thinking its present state a standing disgrace to the country. The Commission which had sat to define the rights therein had done but little, beyond rectifying a few abuses, to benefit the country at large, the Commissioners having taken the very best parts for planting and left the barren places. The fee value of some of the land was valued several years previously at 1s. 6d. an acre, but he was puzzled to know by what particular calculation they arrived at this result. Whether it was supposed to keep the twentieth part of a cow, or the sixteenth part of a jackass (laughter) he could not tell, but he supposed it must have been by some such a process. He should like to hear a practical opinion whether the forest could not advantageously be planted in the barren parts (Voice: "No doubt about that"), because if this could be done there was no reason why the better land should not be sold for the purpose of building or creating estates. He condemned the ancient practice of allowing turf to be cut, as tending to impoverish both the foresters and the Forest itself, by denuding it of soil, and by leading people to cut that which was not worth the carrying home as fuel, and concluded by suggesting that two resolutions should be passed—one affirming the desirability of converting the wood into arable and where this could be profitably done, and the other for profitably utilising the Crown and other waste lands.

Mr. FLETCHER thought there was no portion of the Forest but would grow Scotch fir, and larch might be grown as well, nor were there any portions of it which might not be more profitably used. In certain parts alderwood—a most remunerative wood—might be cultivated. He thought he had been in every county in England, and he could name two or three enclosures in the Forest which contained the finest plantations of Scotch firs he had ever seen. He favourably noticed the management of the deputy surveyor and his officers, to whom great credit and praise were due, and he only wished that their neighbours thinned their plantations so regularly and well as the Forest was thinned. He believed he was justified in saying that the returns for fir were now equal to those for oak.

Mr. FLETCHER, in answer to Capt. Maxse, said there was corn-growing land in the Forest, but, no doubt, the best portion had been taken for the growth of timber.

Mr. JOHN GATER agreed with Mr. Blundell that the best use which could be made of some kinds of land was to plant it with different kinds of firs. A great deal of success or otherwise depended on the selection of the firs, and hundreds of acres lying waste in this country might be advantageously turned to account in this way. As to the New Forest, he thought that when more than half the bread of this country came from abroad we might well turn our attention to applying the many acres of waste there to the raising of corn, and he agreed with Capt. Maxse that our waste labour ought to be turned to a more profitable account. He had no doubt when

Capt. Maxse spoke of waste labour he included our criminals, whom the colonies would not consent to receive, but who might, under a strict guard, be employed in the cultivation of waste lands. No doubt to bring the New Forest into cultivation a heavy expense for drainage, &c., would first have to be incurred, but steam cultivation might be brought into requisition, and an impetus and help given to many mechanics and skilled men, of whom there were so many scores out of employment where there was only one agricultural labourer. He was about to start a steam engine, and he had had 50 applications for the position of driver by good and well-educated men. There were good roads at present in the New Forest, but more were wanted, for a large portion of it was well adapted for gentlemen's seats, having a southern aspect, and good, hand-some timber, such as would fetch large sums on a building site. He thought such places should be offered on long leases, or sold, and what was too poor to invite the attention of the capitalist might be planted, and profitably planted, at the expense of the country.

Mr. ROBERTS thought the subject too large to be discussed in an adequate manner at one meeting, and that the second part, as to the application of the waste lands of the country was sufficiently wide and interesting for a discussion by itself. He had not yet heard how much land in the New Forest was really cultivable with profit. He disagreed with those who thought that gentlemen's seats increased the productiveness of a country; for he could not see how turning land into parks and preserves could be called profitable cultivation. In reference to utilising waste labour, he had for some time past been putting to a practical test the labour lying unproductive in the Winchester Union, and applying it to the cultivation of the land. He referred to a most valuable instrument called a "grubber," which had been recently brought under his notice.

Capt. MAXSE remarked that, when he spoke of applying waste labour to waste land, he merely wanted natural causes to operate in a demand for increased labour, thus using it up.

Mr. PURCHASE gave some explanations as to the course he had pursued in regard to his allotment on Titchfield Common, and added that he was satisfied its reclamation would pay him well.

The CHAIRMAN said no doubt there were in this country many woods that could be profitably broken up; and he had himself done so on land which, in its natural state, only produced 5s. or 7s. an acre, making it now worth 30s. or 40s. an acre. There were doubtless some sorts of land which it would be more profitable to retain as underwood; but there were not, he believed, many large estates in this country which would not pay for the conversion of some of the land into arable, whilst there were hundreds and thousands of acres belonging to private individuals, and now growing nothing, which might be profitably planted. There were thousands of acres now growing nothing but heath, not bringing in 1s. an acre, which, if planted with larch fir, would pay 15s. or 16s. an acre. This, too, would afford employment for a great deal of labour; and if gentlemen, instead of assisting to send our labourers and artisans abroad, would but employ the money they thus spent in increasing the productiveness of their own lands, there would be no need for sending the bone and sinew of the country to other lands (hear, hear). Emigration, instead of being made a panacea for all the ills we were enduring, might be made a great evil, for a large population in a country was an advantage instead of a disadvantage, and if every gentleman would look round to see where he could profitably employ his money, present distress could be materially relieved, and the whole country benefited. Capt. Maxse referred to the quantity of land at Titchfield which remained uncultivated, and suggested that a tax should be put upon it, but the only practical way of dealing with it, perhaps, would be to put on it the fair rate at which it would be rated if cultivated. This would induce its cultivation by the landlord. With respect to the New Forest, which he had traversed scores of times, he believed there was not an acre there which might not be profitably cultivated either for corn or timber, if they would only put the right plant upon the right soil. The secret of successful timber growing was attention to thinning out. His father had some timber valued and re-valued in twenty years. It paid but 3 per cent. whilst standing, but if he had cut it down at the first valuation he might have secured 5 per cent. for his capital, and the land at another use. As to keeping the forest for the production of oak, he recollected when it did

not pay its own expenses, and that might possibly be the case now.

Mr. BRUNDILL in his reply, said there was one thing he had omitted to notice in his paper—the damage done on so many estates by the hedges and hedgerows. There was not a hedgerow in Hampshire paying more than half the money the trees would pay as interest if cut down and turned into money, to say nothing of the damage done to the adjoining arable fields. With regard to the New Forest as a hunting field, it afforded no better sport than the upper parts of the country, and he insisted that even if there were any grounds for such a preservation of it, the necessities of the population were paramount to every other consideration, and these loudly called for its cultivation in the best parts, and planting in the others. Much of the land had been planted for the growth of navy timber, and he maintained that there was scarcely an acre in the forest that could not be made highly valuable. A league, called the Emigration League, had recently been formed in London, to which one nobleman had subscribed a thousand pounds, and he should like to know how many uncultivated acres he possessed on his

estate, for he warranted that he could show him how he could improve his estate and keep his money at home. When by these means the working bees were taken out of the hive how could we wonder at pauperism increasing? It was estimated that fifty miles of railway absorbed a farm of 300 acres, and when we reflected on the land taken out of our limited area in this way and for manufactories it behoved us to try to compensate by cultivating all available land.

The following resolutions were unanimously adopted: 1. That large portions of land in this country now devoted to woods, plantations, and commons, would pay to break up and cultivate, and give profitable employment to the waste labour of the country. 2. That it is the opinion of this club that the most advantageous plan for dealing with Crown lands, such as the New Forest, would be, after satisfying by grants of land all just claims, either by the Commissioners of Woods and Forests or of private persons, to offer to public competition all the remaining lands.

Votes to Mr. Blundell for introducing the subject and to the chairman for presiding brought the meeting to a close.

GROWING HOPS LIKE VINES.

At the December meeting of the Maidstone Farmers' Club, Mr. T. Bridgland, jun., in the chair, Mr. COLLEY attended to explain his new system of hop-growing. After showing that it was adapted to every kind of hops and form of planting, whether square or triangular, he spoke in detail to his system, illustrating it by a model. He urged that this new invention, which has many, and some important, advantages over the old style of poling, can be applied to every kind of hops and forms of planting, whether square or triangular, but it is best suited to a square plant. To commence with this method, two stout poles, moderately straight, are required to each hill as permanent uprights. For Colegates or Golding hops 16 or 18 feet poles may be reduced to 12 feet in length, sawing the tops of the poles in a sloping direction. When these poles are sharpened, they should be thoroughly dipped 30 hours in good creosote at least 26 in. up, and when taken out of the dipping tank hot, which should always be their state, the dipped part should be dusted with lime, slacked for the purpose, or hot ashes from under the tank will serve as a substitute. This absorbs the slimy moisture about the foot of the pole, causing a kind of cement scale or covering, which the fibres of the plant and also the hop roots will more freely approach without being checked by the creosote on the poles. Next, bore a hole through each pole two inches below the top at the side of the sloping cut, large enough for No. 6 or other wire to pass through, which wire is to be cut 12 inches in length. Pass this wire through the hole not quite half the length, and turn up both ends; then press them in a vice close to the pole. Fix a small staple (special for the purpose) driven against the longest side of the wire to prevent the fork (now formed) from turning down, when the top parts of sloping poles are resting between these wire-guards. The permanent poles being prepared should now be placed to the hills from 2 feet 6 inches to 2 feet 8 inches asunder, and not less than 20 inches in the ground, carefully set up by line. If done when the land is in a moist state, the labour will be much less, and the poles will stand more firm than if done when the soil is dry and hard. At this stage, it is indispensably necessary to consider the ground level, which in a great measure should be yielded to, advantage being taken to turn all the tips of the sloping poles to the rising ground, preference being given to the north and south aspects. If the land rises fast eastward, then follow the rise, with the tips of sloping poles; but if to the west, it is better to cross the hilly ground than point to that quarter. When the uprights are so placed, a wooden brace should be nailed across about 4 feet from the ground, to keep the poles a due distance asunder; and however strong the wind may blow, this is a perfect remedy for unsteadiness. A wire staple, two inches wide, should then be placed in each upright pole, about 4 feet from the ground, little more or less, as required. This staple should pass through the pole and clinch, being fixed, to carry the foot of the sloping poles, two of which are required to every hill. These sloping

poles may vary from 10 feet to 14 feet in length, according to the strength of soil and the kind of hop. Light wood and straight poles are most suitable to lay a-slope, and should be sharpened rather flatish at the foot, in order to their binding more firmly in the staples of the permanently fixed poles. The upper part of these sloping poles should rest between the wires provided for that purpose on the tops of the upright poles, and so laid are safely secured during the whole season, there being a combination of support throughout the whole ground, whilst the greatest possible facility is afforded at the time of picking for the removal of every diagonal pole carrying the hops, and likewise at the proper time these poles are all easily again replaced. The ground being once furnished with poles upon this principle, the axe, the line, the hop-pitcher and hop-dog may be dispensed with, and even in dry and very difficult seasons, the necessary polling can be done by a man and boy, at the rate of three acres per day, or by a woman, accustomed to outdoor work, at the rate of one acre per day. The advantage of this system is, that tying can always be commenced whenever the vines are in a fitting state to begin, as there will be no need to wait for the poles to be first set up, nor will any useful vines be damaged by the process of polling before the tyers begin their work. The stock of the hill is (by this plan of polling) at all times protected by the permanent uprights; consequently weakly, damaged, and dead hills will not be so frequently seen, as in grounds poled upon the old style, where the poles are all taken up year by year, and where the crowns of the hills are much trampled on and injured in the time of picking the hop, dang carting, &c. With my improved ladder two rows of poles can be attended to each way; this saves the necessity of moving a ladder round about every hill, as is required to be done by the old system of poling. Eight vines are trained from each hill, four to each upright pole; and when these have passed two feet above the staple on the permanent poles, two vines are taken off each standard and placed on the sloping poles. And here a very important advantage is gained, namely, the sloping poles are made, not dependent upon one hill only, but every pole has two distinct hills to furnish it with vines. The result of this is that when and where hop vine comes very unevenly, or platty, as it is commonly called—one hill having too much vine, and the next, perhaps, too little—upon the patented plan of poling the vines are all so evenly distributed that if there should be here and there a weakly or even a dead hill, every pole is utilised, and is seen to carry hops; and the vines, being all separated into twos, and running on the poles lying in a diagonal or slanting position, trained from two feet six inches to two feet eight inches asunder, prevents the possibility of the hops growing housey, or beating against each other, however severe the wind may be. Again, as the highest of the standard poles is only ten feet four inches from the surface of the ground, both sun and air descend to the lowest branches on the poles,

causing even these to be fruitful and productive. And upon this new plan of poling, if the hops are self-sheltered, they ripen more evenly, the colour is preserved, the weight is increased, and an additional gain of at least ten per cent. is produced in measurable quantity. One other advantage is that when young fruit trees are being raised, or when fruit is growing among the hops, there are no tall poles to overshadow the trees, or any possibility of poles falling to injure them. The horse-work during the summer months can be done without the slightest inconvenience, and there will be no need for digging round the hills, as the whole of the ground can be well and sufficiently worked with the horses and nudgets. Digging and dressing in the spring and all kinds of tillage can be attended to in the usual way. If the hop bine should be attacked with aphid blight, and washing be deemed advisable, upon this new system of poling it can be done more beneficially and at a great saving in cost, as all the leaves, sprigs, and branches are fairly exposed to the ready reception of the liquor applied, while the position of the poles being much nearer to the engine than upon the old style of poling, less force from the pump is required. Consequently not so much bine would be blinded by the process, as is now complained of. And here, with regard to the results of syringing hops, I will just make a passing remark. Having tried various ingredients for this purpose, I have found Fowler's Insecticide, the most effectual of any that I have ever applied—and believe this preparation to be beneficial in more than one point of view, for it not only destroys insect life, but at the same time, invigorates and strengthens the bine, and is an assistance against the ravages caused by mould in hops. If the mildew or mould should come on the plant, and sulphuring appear indispensable, one third of the material can be saved, whilst the labour will be less, and the result much more beneficial than when done upon the old style of upright poling. In picking, the bines should be cut at the staple or junction of the upright poles, and likewise at the top, one foot below the wire fork. The standing poles are then, with perfect ease, speedily detached and lowered to the ground by the bill-hook, specially invented for this purpose. The bines which are entwined round the poles between the staple and the fork on the upright can then be pushed over the top of these poles with the hook already referred to. Hops grown upon this patented plan can be gathered with much greater ease, and at less expense, as they all hang fair, both to the eye and to the hand, having no housey heads or blank tails, to hinder the pickers from freely handling the fruit. Again the stock itself is much invigorated, strengthened, and benefited by cutting the bines four feet high, and leaving the portion below around the standing poles, with the small branches and leaves to take the running sap, which otherwise too freely overflows and greatly weakens and exhausts the root. As soon as the hops are picked from the poles, the bines should quickly be stripped off, for if this is suffered to remain upon them, lying on the ground a few weeks in wet autumn weather, the poles become more injured than the whole of the year besides. Four small blocks and two cross pieces can be placed at suitable distances between the permanent standards, to serve as steadies, two of these blocks should be higher than the other two, and the butts of the sloping poles should be laid one way, to form a thatched like roof. About 400 poles can be laid in each bed, and it would be best to cover them in winter. It should now be remembered that hop-grounds once poled upon this new plan, with a moderate amount of care, will require but a very small expenditure in poles for many successive years, whilst the labour of after-poling will be a nominal consideration. When this is required, provision is made to detach the two upright poles, one row in ten, and lift them out of the ground. This is done by simply fixing a strong wire brace with eye at one end, to be stapled to one of the uprights, and turned at the other end, to drop in a staple fixed to the opposite standard. As soon as the manure is carted on, these poles, together with the wire stays, can again be replaced. Another provision is made by the introduction of an improved three-wheel dung cart drawn by traces. This will run any alley required, without the necessity of removing the poles; may be used in summer or winter, and when shelled it can be taken back to the mixen without being turned. I think the latter provision the best of the two. It may, however, be found convenient to large growers to take up one row in ten when the hops are being picked. With regard to the duration of poles, comment is scarcely ne-

cessary, as any practical man will readily perceive that the difference in cost of keeping up a ground poled upon the old system and that upon the new plan is very plain and indisputable. The 16 or 18 feet poles being reduced to the lengths of 10 or 12 feet (and these all braced together), the great strain and stress which poles necessarily have to endure upon the old principle of poling is entirely avoided; whilst the diagonal poles, which take half their bearing at the foot, in the staple, and resting midway on the top of the upright poles, the wear of these (even if each pole carries a bushel of hops) will be imperceptible for years. Again, upon this patented plan of poling only two twelve-foot poles (to each hill) have to be lifted about, and yet each hill affords more length of pole than is equal to three 16ft. upon the old system of poling, and 36 feet of productive bine may be given to each and every hill of hops. Estimated cost per acre in first poling upon the patented plan, and cost for 14 years afterwards, contrasted with the old system of poling hops. Say ten hundred plant, and where 16 feet poles would be necessary. For the new plan:

	£	s.	d.
2,000 of stout 12ft. poles (say 16ft. cut, at per 100, 24s.)	24	0	0
2,000 of medium 12ft. straight, at per 100, 18s.	18	0	0
2,000 the large size, dipped, 3s. per 100	3	0	0
4,000 wire, 11d. per 100	1	16	8
2,000 small staples	0	18	0
2,000 2½ patent rose nails	0	6	0
4,000 wires, cut to lengths	0	3	4
2,000 turned for staples	0	3	4
Cost to fix wires	1	16	0
1,000 hills to brace	0	10	0
To pole an acre at first	1	0	0
Subsequent expenses per annum per acre for 14 years:—			
Labour to keep up the poles, 15s.	10	10	0
Labour on extra poles, 1s. 6d.	1	1	0
Poling per acre, 1s. 6d.	1	1	0
Extra attention required for tying, 4s.	2	16	0
Total cost of 15 years	67	1	4
£67 1s. 4d. divided by 15 years, £4 9s. 5d. per acre per annum.			
Estimated cost per acre on the old style of poling:—			
1,000 plant, Goldings or Colegates, 3—16 feet to each hill, 24s. per 100—3,000	36	0	0
Dipping 3s. Do.	4	10	0
Poling per acre	0	16	0
Average cost yearly to keep up the poles £4, 14 years	56	0	0
Expense of sharpening, dipping, and cartage of poles, added yearly 16s., 14 years	10	16	0
14 years poling 16s.	10	16	0
Cost of 15 years	118	18	0
or £7 18s. 6d. per acre per annum.			

The figures which I have set forth are intended to represent best poles, and for the most expensive grounds. If for grape hops or Jones', of course the poles would be of a much cheaper character to begin with, but not less cost in the long run. If poles are purchased when green, quickly get them shaved and dipped without delay, as the preserving properties of the creosote, which renders the foot impervious, will follow the pores freely when newly severed from the stub, and will add to the durability of the poles throughout, helping them to last for many years without suffering decay. For the new principle of poling, the poles should be made ready and placed in the ground before the spring of the year, or the ground be dug. In the early hops we picked at the rate of 1 cwt. 3 qrs. 4 lbs. per acre extra on the patented plan, and in quality worth 10s. per cwt. more than those of the same sort grown close by on upright poles. Here we grew 20 cwt. per acre on Colegate hops, picked after the severe gales of wind. We found on the new plan of poling, an increase of four cwt. per acre extra. These were sold at £5 8s. per cwt. Those adjacent, of the same sort, grown on the upright poles, fetched £5 2s. per cwt. This ground yielded about 14 cwt. per acre.

Mr. STONHAM asked what the royalty would be?

Mr. COLEY said he had carefully considered that matter, and had decided to make it of an easy nature—£1 an acre—and this would not be attached to the land, but to the purchaser of it, so that if he at any time removed to another farm he would still be able to grow hops on the same principle. Mr. COLEY then entered into some statistics to show that arguing from his last year's growth, there would be an increased crop, both in weight and value, from the adoption of the principle. There were many, he said, who, no doubt having their poles prepared for the old principle, would not like to adopt it extensively at first, but if they tried one or two acres they would not be running much risk.

Mr. LOVETT said the system would probably interfere with valuations, as the incoming tenant might not desire to carry out the system.

Mr. COLEY said he was so convinced of the advantages himself that if it entailed the drawing of his poles every year he should follow the system.

Mr. CHITTENDEN said he suspected the poles standing would affect their durability. Then, again, with regard to strong bine it might be useful, but with the Jones' or the ordinary Grape the stout poles would not be at all applicable, as they would injure and strain the bine too much.

Mr. BARLING inquired whether Mr. Coley's estimate of the increased yield was founded on measure of weight?

Mr. WATERMAN said there was one thing which had not been mentioned by Mr. Coley which was very much in favour of the system. He visited Mr. Coley's ground after the prevalence of the very high winds of the last season, and he was astonished at the difference in the damage done between the two systems. There was ten times the damage done to the upright poles than there was to those on the new system. He had not gone into the matter thoroughly, but he felt inclined most certainly to try a few acres. He did not see quite so much difference in the cost of the poles as Mr. Coley did.

Mr. STONHAM said he would not go into the merits of the question as to the better quality of the hops; but he thought Mr. Coley had very much understated the first cost of the poles. He assumed that all larch fir poles of the best description were used, and he would not undertake to pole an acre under £100.

Mr. T. REEVES, jun., said he could not understand what there was in the system that it should withstand the wind so much better than the old system. He thought with a strong wind blowing in a certain direction that the poles must come down.

Mr. H. PALINZ inquired as to the extra expense of tying.

Mr. COLEY said he had estimated this at 4s. an acre.

Mr. COLEY replied. In his opinion if poles were thoroughly crooked, that no injury whatever would result to them by standing. He was convinced that when he had once poled his hops they would last as long as he might live. With regard to the cost, he maintained that his figures might fairly

be taken. As to the improved quality, he showed that on the old principle the hops were knocked about and bruised, but his were uninjured, and fully exposed to the light and air, so that they attained full weight. The estimate he made was from measure. A bushel grown on his principle when dried weighed 27 ounces, but upon the upright poles the weight was 24 ounces. He had placed in the hands of the Chairman letters which he had received from gentlemen—experienced hop-growers in the county—who had been eye-witnesses of the damage caused on the upright poles, while upon his system there was not a single pole out of its place. He then showed how, by a simple instrument which he had invented, the wires could be bent so as to hold the poles tightly, which could be easily removed at the time of picking. In reply to the remark of Mr. Chittenden as to the poles being too stout for certain kinds of hops, Mr. Coley showed how by placing the ends of the poles cut off at the hill the weakly vines could be enabled to climb on to the upper portion.

The CHAIRMAN said it was his pleasing duty to move a vote of thanks to Mr. Coley for the courtesy with which he had brought the merits of his invention before the club. His opinion was that the plan was a very useful one, and he cordially wished Mr. Coley success. If it were good, it would be sure to introduce itself; but if it were not, the inventor would gain very little profit by it.

Mr. BARLING then pointed out that he had asked the question as to how Mr. Coley's estimate of the growth was arrived at, as he considered estimates made by measures were always fallacious. He knew that it was generally said that a certain number of bushels produced a cwt. of hops, but no man could so measure without prejudice as to be able to say that the hops he had measured represented actually what another measurer might make of another quantity of hops. If he were asked to give an opinion on the general advantages of the upright and the diagonal principle, he should say, supposing the costs to be nearly alike, that his opinion was decidedly in favour of the diagonal principle. He saw those grown by Mr. Coley, and every hop was fully exposed to the light and air, and he imagined that from this reason there would be increased weight in given measure, and a better quality over those grown on the upright principle. He then pointed out that in his opinion there would be some wear and tear in driving in the staples, and from the carelessness of men putting up the diagonal poles. It was not safe to trust entirely to estimates in all these matters. As a general principle, he thought there would be a gain in quality, but he could not believe that any system would permanently increase the quantity of hops grown.

Mr. COLEY then expressed his acknowledgments for the vote of thanks, and, having produced his letters patent, said he based his calculations of the increased growth on the fact that with the present system there was a large quantity of blank bine, which on his plan became fruitful.

THE NON-RESERVATION OF HARES AND RABBITS.

At a special general meeting of the Warwickshire Chamber of Agriculture, held in Coventry, Mr. J. H. Burbury, the president, in the chair, Mr. MUNTZ, of Umberlade Hall opened a discussion on the "Game Laws." He said that when he issued the circular on the 9th of December last, he did not intend to enter further upon the question at present, but as several members of the Chamber expressed a wish to him that he should introduce the subject to their notice he consented to do so. He was not, however, prepared to say how far the present game laws required amending, nor was he prepared to say whether they should not be altogether repealed. Probably if game was made the property of the land for the time being, and also if there was some protection of it for a particular season, many difficulties might be removed. But his object in writing the circular he had spoken of, and what he had to say was with regard to the position which landlord and tenant would hold supposing the Game Laws were altogether abolished. He wanted to inquire that day, and probably some gentleman present would be able to answer the question, which was, supposing the Game Laws no longer

existed, how would the case be if the landlord chose to keep game on his estate? He did not know that he need allude to the various grievances which the tenant farmers had to submit to, and perhaps they could not too often speak of the injustice when they did so earnestly, thoughtfully, and with a determination to remedy, if possible, those grievances. He would suppose for a tenant taking a farm. He would make his calculations, looking at the quantity of game then existing on the farm, with a view of seeing how much rent he could pay, and get a livelihood out of it. Afterwards, however, he sees his farm overrun with game, and his crops, which he expected to realize, and the profit of the same which he expected to put in his pocket disappeared. But there were still greater grievances than the one he had mentioned. Some of the farmers had been in possession of their farms for years, and perhaps in their families for generations. In towns people changed from house to house, and they thought no more of the house than child. But, in the country, and agricultural districts, it was very different. Every Englishman had his home, and that feeling was not stronger per-

happens than in the mind of the English farmer. In every farm which had been held by the same farmer for a number of years were all the associations of early youth. Why should they forget that the farm, and the farm-house, was the farmer's house, and that he had an attachment to it? Suppose a farmer had lived from his youth to maturer years on the same farm, and had been a good tenant, a good neighbour, and an industrious man, and obliged to leave it in consequence of the overrun of game, it would be a great hardship to him. A farmer generally took his farm for a long lease—21 years—and with a fair quantity of game upon it. He made his calculations so as to get his livelihood and maintain his family respectably out of it. In three years, or perhaps in a less period, the farm might fall into other hands by succession or by sale, and the tenant have a new landlord. The quantity of game may be increased, and a probable loss stare the farmer in the face. Every workman must have his tools to work with, for without them he would be a helpless individual. Every man must have the means by which he could earn his livelihood. How, therefore, could a farmer earn his livelihood without his farm? If a man forgoes all his loss and left his farm, what was he to do, if he could not get possession of a farm at any time? He might rent a large farm and be obliged to leave it because he had sustained so great a loss by game. He did not wish them to suppose that any landlord would willingly allow such an injustice, but he thought this evil arose in consequence of the landlord not being sensible or aware of the damage and injury done to the tenant by the game. What he wanted was this: some means adopted by which a true state of things could be put before the world. He wanted the amount fixed when every tenant when he took a farm should agree to provide either capital or damage for the landlord's sport or pleasure. When there was an increase of damage by game, it should be decided by an impartial judge, and the landlord should pay to the tenant any increased amount above the original bargain. Landlords always made provisions for their own protection, and provided that the tenants should not remove either hay or straw from their farms; and also every other protection they could frame for themselves they put to the agreements. But there was no protection against the landlord walking off with the property of the tenant. An objection was raised against this. How could the tenant interfere? If he opened his mouth about it he was probably turned out of his farm. [A VOICE: "It ought not to be so"]. He would make the matter compulsory, so that the landlord nor tenant should open their mouths. He would make it compulsory by law that whenever a landlord chose to preserve game he should be bound to appoint a valuer, who should make a valuation annually of the amount of damage done. The tenant, as well as the landlord should also appoint a valuer, and the valuation should be laid before both parties, who would then see the true state of things. He was also in favour of making the valuation public, so that everyone might see the amount of damage done by game. One objection might be made in the difficulty of valuing it, and it might be said that no one could make it. He would remind them that if they could not value it, professional men who had had great experience in valuing could be obtained, and who would make it their business to ascertain, as near as possible the true value of the damage done. They must be professional and independent men, who devoted themselves to their business. The next thing was respecting the time when the valuations should be made. He thought that in July or August was the proper time, but he would leave the time of the valuation to the valuer. The crops should be valued at the time when the greatest amount of damage was done.

Mr. MANN, a tenant farmer, was strongly against the continuance of any game-laws at all, and commented on the crime and immorality which they occasioned. He thought the rate-payers should be no longer burdened with the cost of preserving game for sport, and that hares and rabbits should be treated as vermin.

Mr. RICHARDS, another tenant-farmer, was also against the game-laws.

Mr. P. W. MARTIN, M.P. for Rochester, pointed out that as the law at present stood the game belonged to the tenant. The only way in which game could come into the possession of the landlord was by the tenant giving up his right, which he surrendered to the landlord under certain conditions. He quite agreed with the last speaker that the time had come

when rabbits should be dealt with differently from any other animals. However *bona fide* the landlord might act, there was always a soreness about these unfortunate animals, and he spoke from his own knowledge when he said that it was possible practically to give a tenant back the whole of his rent, and yet not satisfy him. Rabbits were a nuisance to the landlord in his turn, and they were the great attraction to poachers. He thought if the landlords of the country would make up their minds to deal in a generous spirit by their tenants, and to pass a measure that concerned this one thing, they would hear little more complaint about the game laws. The proposal that he had to make was this—that a short act should be passed, absolutely vesting the right to rabbits in the tenant, and prohibiting them from being made matter of agreement. With regard to partridges, he believed, from the quantity of insects they destroyed, that they did hardly any harm, but an immense amount of good. As to pheasants, they did not, as a rule, prey on the produce of the farmer, but lived on Indian corn and such things as were provided for them.

Mr. FOSTER, tenant farmer, thought the game laws ought to be entirely abolished. He did not stand there to advocate the abolition of sport, but he did stand there to advocate that sport be put upon a different footing. He looked at this question as a national question and as affecting the whole country in its supply of food. Some years ago Providence visited them with a cattle plague, and Sunday after Sunday they sent up petitions that the plague might be stayed. They deplored the loss of animal food which that cattle plague occasioned, but while doing so they forgot they were suffering annually another loss of food from causes entirely within their own control. He believed the loss of food to the nation in one year by the over preservation of game was greater than the loss in any one year by the cattle plague. The game laws he considered a remnant of the feudal system, and he said, "Let us make a clean sweep of them." He thought if landlords treated their tenants fairly, and left the preservation of game entirely in the hands of their tenants, they would require no gamekeepers, and would never want a good day's sport. Gamekeepers he considered a very great nuisance to the farmers; they were generally taken from an uneducated class of men, and made themselves offensive in many ways. They were, to a certain extent, set to watch poachers, but they rather watched the farmer and they generally made more mischief between a landlord and his tenants than it was possible for him to describe. He said, therefore, do away with game laws; do away with keepers, and there was not a tenant in the country that would not take a pride in providing a reasonable amount of sport for his landlord and in carrying a gun with him. He condemned the battue system, and saw with regret the encouragement which had been given to it by the Prince of Wales.

Mr. S. B. CONGREVE, tenant-farmer, thought hares and rabbits should be struck out of the game-list. He did not think partridges did much harm, although pheasants did. But what they wanted most was, to get rid of the nuisance of preserving large quantities of hares and rabbits. As to Mr. Muntz's proposal, he thought it impracticable. Mr. Muntz spoke about getting an impartial man; but where would they find him? He spoke about a professional impartial man, but what would a professional man know about it? Those professional men who did not lean to the landlords' side would get devilish little employment.

The CHAIRMAN here intimated that a telegram had just been received from Mr. Newdegate, M.P., senior member for North Warwickshire. It was as follows: "I much regret that I am prevented attending the meeting of to-day. I hope you will say this for me. I have read Mr. Muntz's letter. The annual valuation, if enforced by law, would be an arbitrary measure, and lead to great inconvenience both to tenant and landlord. It would be simpler to declare that the game belongs to the tenant, all agreements to the contrary notwithstanding. This would be unjust without power to alter the rent. The remedy for any evil which exists seems to be in specific contract between landlord and tenant, without the intervention of third parties, except by agreement between landlord and tenant."

Mr. BROMLEY DAVENPORT, M.P., was unfavourable to Mr. Muntz's proposal, which he thought would prove difficult in working. He understood from this meeting that there was no objection to landlords coming down to shoot. The ob-

jection was the excess in preservation of game, which, like all other excesses, was bad. He thought, if some provision could be made whereby rabbits could be more decidedly left to the tenant than they were, or, if you will, all ground game, that it would conduce to a more satisfactory state of things. Practically, he might say that on his estates every tenant of his had leave to kill rabbits; and therefore, in regard to them, he never had any complaint except from one or two small tenants who lived near the wood, and whom he had always endeavoured to compensate. As a landlord he was in favour of preserving game in moderation, but not in excess, which he regarded as intense folly. Referring to battues, he said he had seen in the papers the most absurd and exaggerated statements regarding that mode of sport; as, for instance, that the excess of game was buried. They had seen that statement made in the papers, but had anyone seen it in practice? Equally absurd statements had also been made by men who did not know anything about game or game-preserving, or the

relations between landlord and tenant. He had seen a London leading article in which the writer, commenting on the hardship of farmers being obliged to preserve game, said, "What, for instance, could be more unjust than that tenants should be compelled not only to keep the rabbits for their landlords, but even be obliged to preserve their eggs?" His feeling was that something should be done by the Legislature which should have the effect of diminishing the quantity of ground game; but if a tenant had no objection to an arrangement with his landlord whereby the landlord could have a reasonable amount of sport, then they had no right to use compulsory legislation. "That rabbits and hares should be the absolute property of the occupier of the land, and that any agreement to the contrary between landlord and tenant should be null and void."

The following resolution was unanimously adopted, as it appeared at the time; although as a county member Mr. Bromley Davenport has of course since expressed his dissent.

DORCHESTER FARMERS' CLUB.

STEAM CULTIVATION.

The members of this Club, who tried the experiment of holding meetings with closed doors, have returned to their former practice of inviting reporters to record their deliberations.

At the last meeting, Mr. RICHARDSON, the representative of Fowler and Co., of Leeds, said: The subject of steam cultivation, which he understood had not previously been ventilated in the county, demanded their serious attention. Practical experience as a member of the firm which had been instrumental in introducing steam cultivation in other counties had led him to conclude that sooner or later it must be adopted in every county of the country. When he told them that the great pioneer of steam cultivation was the Viceroy of Egypt, who had ordered £70,000 worth of machinery of Messrs. Fowler and Co., he thought they would rest satisfied that if the farmers of England did not progress in that matter foreigners would tread on their heels. The gentleman who had managed the machinery supplied to the Viceroy of Egypt was a young German, who learnt farming. At the time of the cattle plague the Viceroy was driven to his own resources. During the year of the great international exhibition he had seen the steam plough of England at work. When his cattle were dying by hundreds and thousands, and when cotton was at a fabulous price he sent a telegram to Messrs. Fowler and Co., asking them in what time they could supply him with 20 double steam ploughs. The answer was "four months, provided that £20,000 is lodged at a London bank." Within four days the money was lodged, and the Viceroy had since been supplied with 75 double steam plough engines. Mr. Richardson afterwards proceeded: It is not my intention to treat of the mechanical part of this subject, for I am aware that many and various opinions are held respecting the different adaptations of machinery necessary to encounter the greatly-varying nature of the soils. But all descriptions have been brought to a high degree of perfection, and, therefore, the farmer has little difficulty in selecting the one which is more particularly suited to his own immediate requirements. Moreover, the system of hiring out machinery in the shape of two powerful traction engines has made steam subservient to the wants of all classes of agriculturists, and with proper management this system can and will economise the working expenses of the farmer materially. Labour, whether animal or manual, is a very serious item of expense to the farmer, for the former has been confined to the grain-consuming horse, while the latter is daily demanding higher wages, which tends to lessen the farmer's profits. But a brighter mora is now dawning upon his prospects. After years of expensive and laborious experiments, that all-powerful, untiring agent, the steam-engine—the great abridger of time and labour—is now ready to prove to the farmer as tractable and serviceable in the field, when attached to the plough or cultivator, as it has hitherto been while setting in motion the various machinery of the farm-yard. The year 1869 has not

been a year of great productiveness or prosperity to the agricultural interest and to the county. But judgment and industry combined will, with the assistance of mechanical skill, insure to the husbandman more safety and stability, freedom from preying anxieties, and greater ability, with a proportionate capability to supply the increasing wants of an increasing population. It is very gratifying to note the great interest everywhere manifesting itself in favour of steam cultivation, and to discern the gradual crystallising into form of the crude views at first entertained as well as the partial dissolution of those prejudices which at one time apparently threatened to oppose such an improvement in the field of labour; and it must tend to confirm our belief that a grand and sublime development of practical and industrial ideas, however slowly accomplished amid embarrassments and discouragements, will at length be acknowledged one of the crowning glories of this noble kingdom. It is a fact, too, that cannot escape the attention of the observing class, that men of superior education and wealth are now taking an interest in farming, giving to the world the benefit of scientific experience and research, and pursuing their vocation with a view to render the labourer a more mechanical agent, and thus obtain from him his mental in lieu of his animal power. We must all admit that England has surpassed all other nations in the excellence and variety of its agricultural machinery. Now all improvements in agricultural machinery have a tendency to reduce to the lowest minimum the proportion of animal and manual power employed in its operations. I will now propose to consider four points connected with this subject—First, the advantages to be derived from employing steam power in the cultivation of the land; secondly, the economy which will be effected in all the tillage operations on the farm; thirdly, that the work can be done at precisely the proper time; and fourthly, and the most important of all, and one that constitutes the gist and pith of the whole subject, that the produce of the land can be materially increased and the cost of production decreased. First, then, I will consider the advantage to be derived by employing steam power in cultivating the soil. As an instance, the steam thrashing machine, at one time the fail—worked, of course, by manual labour—was at length superseded by the horse thrashing-machine, or animal power; whereas it has now succumbed to the mechanical power of steam. The further this saving of both animal and manual labour progresses, the greater will be the profits of the farmer, and the more extensive become the garneries of the world. Coincident with this application of mechanics to agriculture, systematic and enlarged business aptitudes will seek alliance with this noble art. Farms of hundreds of acres will be managed with more skill, and a larger margin of net profit than even farms of smaller extent, for the larger the farm (so long as it is within the means and capacity of the manager) so much the better and cheaper will it be cultivated. In view, then, of all these evidences of the progress and of the expanding capabilities of agriculture, I

have pleasure in introducing to your favourable consideration the steam-plough or cultivator, believing you will give it a trial, after hearing the great advantages it possesses over all animal and manual power, and encourage it with that spirit of liberality which becomes a great and important county. And when we consider that but a few years have elapsed since steam cultivation was only an idea, and that the inventors had no previous models or similar appliances to work from, but had first to discover the principles and then apply them in all their details to the invention of proper machinery, the present developed condition of the steam plough or cultivator is truly wonderful. We must all admit that our gardens produce much more (whatever the course of cropping) than the same area of land does in any part of the farm; and a satisfactory reason can be assigned for it. It is in consequence of deep trenching, a thorough loosening and mixing of the soil, and the non-compression of it by treading with horses' feet after the process of digging or forking it over. Such, then, is the case with the steam cultivator. All the roots and plants are allowed to penetrate through a soil thoroughly disintegrated or broken up, being in no way intercepted by a hard subsoil or indented path, upon which horses have trodden for years; consequently a complete change is effected in the nature of the subsoil, and more particularly as regards its drainage, and this on strong soils is a most important feature, for the drainage of all strong tenacious lands is the first step towards improving it. But the practical solution of the great advantage of steam cultivation on all strong soils is that all treading is avoided. Moreover, there is an old inspired credence, that "the clouds drop fatness." Therefore I consider water must be the great fertilizing process, if by proper cultivation it can percolate freely. But can such be the case if the subsoil is not broken up; or if the land is consolidated or compressed by the action of the plough irons, the squeezing of the mouldboard, the landside, and sole of the horse plough, together with the horses' feet? For the sake of explanation I will take a team of three or four horses, ploughing a 10-inch furrow. They will leave more than 300,000 footprints on the acre, and, since these nearly cover the ground, the effect will be a hard subsoil or pan beneath the cultivated ground is left, which becomes worse with every successive ploughing at the same depth. Now the tractive power which horses are able to exercise upon a plough is very limited, and is further decreased in consequence of their having to convey their own weight over the land, as well as partly to undo the compression caused by their own feet. I will just practically illustrate this, since it is of such importance. Suppose a horse is taken when the land is wet, or in a waxy state, and walked across the track of a steam plough, and made to travel to and fro transversely on every ten-inch width until a breadth of six yards is trodden over, it is ascertained that if the steam-cultivating engine has just sufficient steam to perform its work properly before it arrives at the ground so trodden down, it will be completely stopped before it gets through the six yards; and, considering the momentum of the fly-wheel, this experiment clearly shows, and plainly and practically convinces us, that the power required is something very important; and experience further shows that one-third additional draught is required on land so trodden down and consolidated. Now, there is no treading or poaching the land by the steam cultivator. The engines stand on the headland, and draw the implement to and fro by means of a wire rope. It is driven at a much more rapid speed: it throws up the soil in a loose state, and thereby enables it to derive considerably more benefit from the influences of the atmosphere acting upon it. The rapid motion of the steam-driven implement tends also to loosen and aerate the soil much below the actual depth at which the tyre or share is working. But in horse or ox ploughing the case is just the reverse, for the soil of the plough and the treading of the animals so consolidate the subsoil that the necessary chemical action between the soil and subsoil, and consequently all escape of water and gas, is entirely prevented. The result of tearing up and loosening the subsoil is that a much greater quantity of ground is penetrated by air, and its temperature is thereby raised. The air is replaced in the same proportion by water (when rain falls), and this moisture is retained in the steam-cultivated ground as if in a sponge, any superfluous quantity sinking away to the drains beneath, instead of the whole lying for a long time in a hard and trampled subsoil as though held in a dish, making

the land cold and ungenial. As regards the temperature of the soil, I am satisfied, from practical observation, that this subject in connection with agriculture demands our investigation and consideration, for the improvement of the temperature of the soil is directly accomplished by the improvement of its drainage, as aeration and its power of absorption and evaporation. A high temperature of the soil materially assists the growth of plants, and that temperature cannot be kept uniform except by deep cultivation and an equal looseness of the bottom soil. I have frequently seen fields of wheat in the spring time turn completely yellow in three or four days, arising, in my opinion, from shallow cultivation, the water not getting beyond the horse-beaten surface of the subsoil, thus producing a low and injurious temperature; but the case is altogether altered if you cultivate very deep and break up this board or pan, and so allow the water to get away into the drains. With such a quantity of loosened soil as I recommend, say two feet, on all strong soils, it must be obvious to everyone that, so long as the excess of water can pass readily away, it will not cool the land, but will, on the contrary, rather tend to heat it, and leave in the soil its ammoniacal properties. The temperature of the air is of less importance than the temperature of the soil, as regards the healthy state of the plants, for an early development is of vital importance to all root crops, for if you once get the root to take good hold of the soil the probability is that the crop will continue healthy and luxuriant; but how can land be kept in an even temperature when horses have trodden and left with every foot-print a sort of basin for the water to stand in? These remarks, of course, only refer to strong, heavy, and tenacious soils; but a similar result is observable on light lands, but of course they are not so damaged by wet or excessive moisture. Their greatest danger is from "burning" in dry weather; but deep cultivation and loosening of the soil causes them to retain their moisture in a dry season for a much longer period than if the subsoil might be what is termed a board, then the roots of the plants have more liberty to penetrate the soil until stopped by natural causes. They can follow the moisture in the ground much further than would be possible after horse cultivation, for, since no burning takes place until the deepest roots have entirely exhausted the moisture around them, the crop is made capable of resisting the action of heat and the effects of drought for a very long time. I am practically convinced that the success or otherwise of a root crop depends upon the number of cubic feet of soil that the roots are able to penetrate; and I am satisfied that a grain crop on light lands will stand up much better and is not so easily laid on a deeply cultivated soil as one which is shallow. But a further and additional advantage is obtained on light soils in the greater facility offered in eradicating couch grasses. The horse implement, from want of power to go sufficiently deep, cuts the couch into small pieces, very frequently leaving the roots in the ground, which must afterwards undoubtedly rise up in judgment against the occupier, and, being brought to the surface in small pieces only, the horses' feet while harrowing transplant a considerable portion of it, which of course necessitates more draggings and numerous other operations. But this brings me to the second part of my subject, viz., that by steam the tillage operations on the farm can be effected more economically. At present I must admit that the cost of performing tillage operations by steam is far from being so cheap as it should be or what it eventually will be. In many cases, and especially in regard to steam machinery worked for hire, the very worst and heaviest portion of the work is given to it, and very frequently that which cannot be done by horses. Now, before we obtain the maximum of cheapness, we must allow steam power to perform all the operations connected with the tillage of the ground, for if after steam cultivating a field horses are taken upon it, for the purpose of harrowing it or doing similar work, the ground is of course trodden down again and consolidated. The consequence is, the next year it requires much more power to break it up than would otherwise be the case, and not only does it require this extra force, but clod-crushers and other implements have to be applied to it, which should not be the case if it had been worked immediately after harvest time, or when the land was thoroughly dry. The generality of land, if worked by steam power and kept entirely free from the trampling of horses, would only require one very deep cultivation every fourth or fifth year; and would be kept in such a

state as to allow the air and moisture, together with the roots of the crops, to penetrate freely, so that the cultivation of the corn crops in their proper rotation would only require a light or surface operation sufficient to cover the seed. We may not be able to calculate the precise amount of increase in proportion to an additional inch obtained in depth; but experiments have proved that in many cases it bears relatively a near proportion to the increase in depth of culture, so that, when the soil is only worked to six inches, an inch greater depth of cultivation would give nearly one-sixth more production. An erroneous impression exists relative to the depth to which the roots of the cereals and clovers, as well as many other plants, will descend in a well cultivated and fruitful soil. In pits filled with surface soil, or wherever the mould is of suitable texture and condition, carrots and parsnips are often found of a length of three feet or more, clover roots from three to four feet, and instances have been known of still greater length of the roots of wheat and oats. But with the prevalent mode of horse culture, in very compact soils, wheat roots are so near the surface as to be thrown out by the mechanical displacement of freezing and thawing, and, if not utterly destroyed, they struggle fruitlessly to pierce the unbroken subsoil, packed, perhaps, by the tread of horses for a century or more, and finally yield to the blasting power of an early drought, and become blighted, light, shrivelled, worthless for seed, and of no value for bread. Now deep culture with proper drainage will procure exemption from most of these liabilities, and more especially on light soils, from all danger of loss from drought. Deep cultivation then and thorough pulverisation is a prime necessity for all root culture, and in no way can deep cultivation be so cheaply and more economically performed than by steam power. This, then, brings me to the third part of my subject, and I will endeavour to show that the work of the farm can be done at precisely the proper time. I must admit that the cultivation of the soil is a business which requires a great amount of care and attention, combined with practical experience. A very false idea of a farmer's business is conveyed when it is said that any one is fit for farming. On the contrary, I do not know of any business which requires such minute attention and such keen observation, and this arises principally from the extraordinary variations in the climate, weather, and the soil, and the great and important effect these variations have upon the crops. These farmers who most carefully observe the state of their land, and never work it except at proper times, will, of course, derive the greatest advantage from it. On a farm under horse cultivation, however, this is a very difficult task, as the small amount of profit yielded by farming will not allow the number of horses, implements, &c., to be kept which would be necessary to deal with all the land at the proper period and in the most economical manner. This inability, then, to deal with the land when dry and in the best condition, involves its deterioration until it can scarcely be considered to be in growing condition, and not unfrequently the total or partial loss of the crop is thus caused. When we consider that there are only two or three months in the year during which the tillage operations can be profitably performed, the fact that the horses are sometimes kept working continually in order that they may not fall behindhand with their work shows clearly that the land must often be operated upon when it is in a very unfit and improper condition. But the person who farms by steam has a powerful and ample force at his disposal, so that he can afford to wait until his land is in a fit state for working, and this force being an untiring one he can work night and day if necessary to complete those operations for which the season will not tarry. It is often customary to hear farmers complain that they have got behind hand with their work, and they will point out a field, or perhaps two, in which the crop has been nearly lost, simply because it was put into two or three days later, or when the land was really unfit for the reception of the seed. Now this occurs because the farmer is usually obliged to keep his working force of horses down to the narrowest possible limit, and the consequence is that in some unfavourable seasons he requires twice the number at his disposal to complete his work in proper time. But what I have shown and I trust convinced all practical men is that these irritating and expensive difficulties are almost unknown to the man who farms by steam. Such being the case, I will proceed to point out lastly that the produce of the land can be considerably increased and the cost of produc-

tion decreased. This is the most important part of my lecture. To accomplish this, however, science and practice must go hand-in-hand, for Liebig, the greatest chemist that ever lived, has stated that deep pulverisation of the soil was attended with most important results, for he had discovered that when the surface of bodies was exceedingly extended by a minute comminution of their particles they could condense 80 times their substance in gasses, as, for instance, a piece of beechwood when powdered and reduced to a state of charcoal. The effect of this, then, in a finely pulverized soil would be to absorb and intensify the action of the atmosphere upon that soil, and thus absorb 80 times the amount of air. Thus, then, science confirms the daily and practical experience of agriculture. It explains the whole system of fallows, the whole system of the rotation of crops, for in this way the whole action of the atmosphere upon the soil was so deeply intensified that the soils which were made fallow entirely altered their chemical character, and, farther, the rotation of cropping was only a different kind of fallow, for a crop was put in which did not exhaust the soil instead of one which had exhausted it; and in this way, by the action of the air (which after all is the great pabulum of plants) upon the soil, those mineral constituents which had become deficient were obtained. By these remarks I only wish to justify the importance of science as closely connected with agriculture, for all scientific and mechanical inventions which assist in the pulverisation of the soil will confirm and strengthen the importance of employing steam as an agent to carry out the operations with advantage. But, as I said previously, science and practice must work together, and all the inventions of the mechanic must directly or indirectly pass through the practical and observing mind of the agriculturist; for by their skill, frugal industry, enterprise, and capital, land once barren and unproductive have been made to unfold the most luxuriant crops of grain and turnips. Take, for instance, the improvements made by the tenant farmers in Norfolk. That county is a triumph of English excellence in agricultural pursuits. There, where at one time two rabbits fought for a blade of grass, you can now see a wide waving corn field, and I feel convinced that if the farmers of Dorsetshire or any other county will make up their minds to employ the steam cultivator, if only as an auxiliary on their farms the result in improved crops will fully justify the expense. In support of this statement, then, I will read you an extract from a letter written by Mr. Bailey Denton to the *Times*. I can also show you that in the application of artificial manures to the land a very economical feature suggests itself, for I have known an application of only one sack of bones to the acre after steam cultivation for a turnip crop produce a larger crop of roots than from an application of two sacks after horse culture, and the trial was made in the same field. I account for this in consequence of the one sack of bones becoming immediately available to the plant, in consequence of the soil being thoroughly pulverised by the action of the steam cultivator, and, the bones becoming more mixed with the fine soil, they formed a continuous supply of increasing nourishment to the plants. Now, I have asserted that not only can the produce be increased, but that the cost of production can be decreased. I find from careful observation and practical experience that, including interest on the outlay, depreciation, and repairs, the average yearly cost of maintaining a set of steam tackle working 2,000 acres per year, say six or eight inches deep, will be £300 or 3s. per acre. Now, how many horses would be required to work 2,000 acres? Allowing a pair of horses can plough one acre per day, it would require a team of 20 horses to average 10 acres per day, or 60 acres per week, 240 acres per month; and they would be employed between eight and nine months before they had completed the 2,000 acres. Now, the wear and tear of the harness, implements, and the amount of farrier's and other bills in connection with these 20 horses, with interest and depreciation, will be at least twice as great as the corresponding items, which are chargeable against the steam-ploughing tackle. The average price of coals per horse-power per day—i.e., the cost of the quantity of coals we should burn in an engine to get out of it work equal to one horse or half-an-acre per day—would be 7d. Can you, as practical men, convince yourselves you can maintain a horse a day for that sum? For an engine only requires food when working, whereas horses eat night and day, and, moreover, require many hours for rest; but, with a

relay of hands, you can work an engine night as well as day. But I will put it more plainly still. If, under the present system of working with horses, a farmer could take each field consecutively, and attempt to calculate beforehand the cost of the different operations required for cultivating it under ordinary circumstances, he would probably find that such an estimate would have to be doubled before it would cover his actual expenditure, and this in consequence of wet days and other contingencies compelling him to keep his men and horses idle. Now, such a state of things in any ordinary mercantile business would be ruinous, and this is the great drawback in all calculations connected with farming where horses are the motive power. Surely, then, the cost of production can be proved to be decreased by employing steam-power, because the actual cost of cultivating the land is known and agreed upon before the engine enters the field. Such being the case, and until there is a supply of steam-cultivating machinery to meet the increasing demand of the farmers, they must rely upon horses, and are at any moment liable to be compelled to pay advanced wages to their labourers; consequently, I fearlessly assert that the farmer has greater difficulties to contend with than any other producing class. The powers of machinery are controlled, mastered, and subdued by art; but the powers of nature in her wild state are encountered by the farmer in the mildew on his corn, the murrain amongst his stock, the seasons too wet or too dry—all these combined tend to try the indomitable pluck of the English agriculturist. Consequently, how important that they should meet together to communicate their ideas and obtain information in a manner not only agreeable and useful to themselves, but also advantageous to the general welfare of the community at large. I wish, then, every success to your club, for by it you are diffusing sound, practical, and useful information; you are, in fact, promoting the progress of agricultural improvements; you are not merely developing the national resources, you are not merely lightening the national burdens, you are not merely adding to the strength and power of England, or increasing the wealth of those who are already wealthy, but you are indirectly engaged in one of the highest and noblest tasks which human enterprise can propose to itself, and, by employing machinery, you are relieving the sufferings and elevating the condition of the labouring classes of the country. And I must dwell particularly upon this, because I confess it gives the whole subject of steam cultivation an interest which otherwise it would never possess, for the higher the farming becomes, and the more machinery you employ, the less need will there be for mere brute labour, and the more you will require skilful and cultivated intelligence, for you will exercise the mental in lieu of the animal power of your labourers, or, in other words you will have less demand upon their muscular strength and a greater demand upon their brains. "Necessity," we all know, "is the mother of invention," and she is not giving birth one moment too soon to a system most essential, highly necessary, and conducive in a great measure to the happiness, comfort, and prosperity of all who are or who will be engaged in agricultural pursuits, for experience, the best of all school-masters, is everywhere establishing a common credence in the great necessity for employing mechanical inventions. But they must be brought before the bar of practical experience and then stand or fall upon their own merits. A practical and sensible man only can succeed or make money by farming for (in the face of the numerous difficulties I have enumerated with regard to the seasons, &c.) a farmer must have the intelligence of a mechanic, the business habits of a merchant, the mathematical talent of an accountant, and the shrewdness and perceptive genius of a banker. Yes, he must have all these individuals' talents concentrated within his own breast; he must be a mechanic to understand the construction of the implements brought before him; an accountant to enable him to keep an accurate account and record of his outgoings and incomings—his experiments, profit and loss, &c.; a merchant to know how and when to buy and sell cattle or dispose of the products of his labour to the best advantage; and a banker to discover when drainage and fertilisation will prove a better investment for surplus profits than funds or railroad stock. On this account, therefore, I say the dolt of the family must not be selected for the business of farming. For, as the population of the earth increases, the necessity for a more careful and improved tillage becomes apparent, and its importance in this country at least cannot be over-estimated. No

limit can be assigned to the increase of population, unless it be from the want of means to sustain animal life; and hence it follows that, with an increase of human life, there must be a corresponding increase of the means to support that life. The application of steam power to the propulsion of machinery for the purpose of travelling and transportation has proved a success beyond the most sanguine expectations of its warmest advocates. No animal power can possibly compete with it. It is as untiring as the sun in his course; and when its day's work is done, it needs no rest, but is ready at a moment's notice to renew its task. Can we doubt, then, for a moment, that it is destined to supersede animal power in agricultural operations? Briefly, then, to sum up the advantages derived from the steam plough, I have endeavoured to show that it will cultivate more deeply, cheaply, and rapidly, leaving a mellow and warmer soil. Its rapidity of execution enables the farmer to cultivate a larger area at exactly the time to secure the best possible results. It excites greater activity and promptitude amongst the labourers, and leads to habits of system and order in all their operations. It substitutes artificial or machine power (always attainable to any extent) for animal power and manual labour, which are often unattainable to the extent required. It secures uniform seeding and ripening of the crops, for the same engine can at the time of ploughing also sow and harrow the ground by having sufficient power to draw all the implements at once. And in this mode of cultivation, novel to perhaps many of you, we shall have pleasure united with profit, ease with enhancement, dormant earth below made to revive the exhausted soil above, and all improved; and in all this process the mind as well as the purse is filled and benefited; for deep cultivation, by which a warm, dry, mellow, and improved soil is produced, is the true acme, the real charm and test, of good farming, and is not second even to a wise adaptation of good seed to soils. Unless, then, the farmer keeps pace with the spirit of the age, uniting art with science and science with mechanical skill, he will find himself in an inferior grade, where he will enjoy less of the blessings, the treasures, and refinements of life, and endure more hard work than any other classes: for the experience of all enlightened communities proves that the necessities of life, as well as its luxuries are cheapened and improved in the same proportion as the ingenuity of the mind guides the power of the muscles, and the mechanical powers supersede the animal forces. Then the nation at large will derive benefit from the increased yield of crops, as well as from the fact that the materials to feed the power used in tillage operations will be drawn from the coal mine or the forest, instead of being taken from the produce of the fields. We shall not be obliged to import so much corn as hitherto, and a larger percentage of the crops will be converted into food for human beings instead of food for horses. Then will farmers prove "benefactors to their country" in every sense, for they will not only increase the yield, cheapen the cost, and lighten the labour of obtaining the necessities of life, but they will give convincing proof that they appreciate the labours of those who have spent their time, money and energies in this glorious attempt to uphold the character of British agriculture, to maintain her position as a nation on the face of the globe, and will acknowledge steam cultivation not only a fact but a glorious triumph of human genius over mere soulless matter, and one which, if encouraged, will more fully develop the character of Englishmen than any invention yet introduced—will also materially assist in alleviating the wants of our poorer brethren—have a tendency to increase our wealth as a nation, as well as add strength, glory, and honour to our British Constitution by elevating the condition of all classes in society.

Mr. J. G. HOMER, the Chairman, was one of those old farmers who had used but little and therefore knew but little of steam power. Some practical men would perhaps like to offer a few observations. There was Mr. Barnes, for instance; no man had had greater experience than him in steam cultivation.

Mr. BARNES had certainly had long experience. He should like to hear Mr. Richardson show how he had managed steam cultivation at 8s. per acre. His own experience of five or six years did not enable him to see how it could be done at that price.

The CHAIRMAN: Give us your opinion as to the merits of steam cultivation.

Mr. BARNES : I decidedly recommend it. I should not like to manage a farm without it. I mean a farm of extent—say over 400 acres. Steam power we shall see more used than ever. I should not like to be without it.

Mr. H. TAYLOR said his own experience in steam cultivation extended over six or seven years. A few friends had hired his tackle for steam cultivation, but he had never been able to do the work at 3s. per acre, nor had he known it done at that figure. He should be very pleased to do so, but he had never used any of the double tackle on Fowler's new principle. Perhaps with that tackle he should be able to carry on steam cultivation at 3s. per acre with a profit; he should be very pleased indeed if he could do it. He thought that at present few men letting out steam tackle for hire could accommodate many customers, at least as many as there were likely to be in Dorsetshire. Certainly those who hired out tackle would not be able to manage with one set or yet with half-a-dozen sets, and it was not likely that they would pay, considering the limited time they would be required—say three months. It must be remembered that the tackle was very expensive. He had a set which cost him a considerable sum, but he was happy to say that he had put something into his pocket—the tackle had worked very satisfactorily. He thought that if he were a farmer and had 400 acres of arable land he should have a steam cultivator. The way to make steam cultivation pay was to work say half-a-dozen farms after harvest consecutively, doing perhaps 50 acres per day. The job, however, was to do that amount of work; he had found ten acres enough. But, as he had just said, he had not yet used Fowler's double tackle. The other day he saw two or three sets of tackle sold, and on the farm one of them stood still while the other was at work—which was not a very prosperous game. Mr. Richardson might possibly be acquainted with the soil of Dorset; perhaps he would kindly state what he thought would suit the Dorset country best. He felt convinced that Fowler's ordinary cultivator would not suit this country. Mr. Taylor spoke highly of Smith's implement—constructed on the "turn-round" system. No implement for steam cultivation which had come under his own notice was like Smith's "turn-round"—he had worked Smith's tackle for six or seven years.

Mr. JOHN GALPIN was one of the first in this neighbourhood to introduce the steam-plough for hire, and he found the difficulty which Mr. Taylor had expressed. He could not please everybody, and was glad to be relieved of the chance of offending everybody. It perhaps might be worth the experiment to keep a steam-plough between two or three farmers. As to which implement was best adapted to do the work, he would leave that to those who were more experienced than himself. He had used Fowler's which gave very great satisfaction as far as it went; it had the power of turning up the land a greater depth than any customer wished to have it. As to the merits of Smith's implement he believed it might be worked most economically. He agreed with Mr. Richardson regarding the steam-plough that you must not judge of the value of it by one experiment. Mr. Richardson had very ably laid before them the advantages of steam cultivation, and there were many gentlemen present whose practical knowledge on the subject enabled them to speak thereon. As regarded Mr. Richardson's estimate of 3s. per acre, he (Mr. Galpin) found that he was obliged to charge more than 3s. or 3s. per acre, and then with little profit to the person hiring. He hoped that Mr. Richardson would explain his estimate, because that was a very essential point. Of course, all would be in favour of steam cultivation, provided it was the most economical, and on this point it was important that they should have before them the actual and not merely isolated facts. He hoped they would have a full explanation from Mr. Richardson on this important point. As to the value of the steam-plough there could be little doubt.

Mr. DUKE, in response to a general invitation to say a few words, observed that he had used a steam plough for six or seven years. He would not now do without it, but if he had not one he would not buy one. He had, however, bought it and paid for it, and very useful it was; it did double the amount of work done by an ordinary implement. He would remind the meeting of the differences in the nature of the soil, some being light and others quite the reverse; and consequently, as he pointed out, different cultivation was required. He spoke of the inconveniences and difficulties occasioned by the shifting of the tackle, apparently forgotten in calculating

3s. per acre for ploughing. He had himself kept a correct account of the work which he had done. He could not do it at less than 6s. per acre, and he did not think any man could do it for less, reckoning everything. He agreed entirely with previous speakers on the point that the steam plough would double the amount of the work done by the ordinary plough. He pointed out that for the steam plough to be remunerative there must be considerable work—the owner must at least have 500 acres of arable land. [He used Howard's tackle; he thought Smith's was very good.] On small occupations of from 100 to 200 acres, where the fields did not extend over more than ten acres, the work could perhaps better be done without the steam plough, in consequence of the time taken up in shifting of tackle and getting water. While the latter was going on the ploughing could be done by horses. In conclusion, he repeated that he should not get rid of his present steam plough, but that if he had not one he should not buy one.

Mr. GENGÉ thought that Mr. Richardson's remarks were all on one side of the question. They had heard the opinions of gentlemen on the opposite side, and now they had to draw their own conclusions as to the advantages or otherwise of the steam plough. The question for their consideration resolved itself into this—whether a set of steam tackle was desirable or not on a farm. That, he thought, depended entirely on the extent of the farm. The system of hiring was, he considered, a very convenient one. There was this drawback, however, you could not always get the tackle at the precise time you wanted it. That was the rock on which so many split. Such was the amount of capital required to be invested in steam tackle that he was afraid it would be unproductive unless an extra price was charged for the work. The great point for consideration was the saving of horse labour. If you kept 80 horses and you could by the use of steam tackle dispense with most of them it would decidedly pay to effect the alteration. Mr. Gengé agreed that the differences in the character of the soil to be worked was a point of great importance for consideration. He was decidedly in favour of the steam plough on large farms. There must, he said, be plenty of work to make it pay.

Mr. G. W. HOMER also dwelt on the importance of there being a large extent of land in order to make the steam plough pay. He pointed out that on an extensive farm there was a deal of work to be done in the removal of stubble.

Mr. CHAPMAN SAUNDERS pointed out that the treading of the horses over the land in many cases did good.

Mr. DUKE reminded the meeting of the advantage of manuring the land well.

Mr. T. LOCK brought before the meeting the value of getting in the crops at the proper season.

Mr. ATKINS should say that the work could not be done at 3s. per acre.

The CHAIRMAN had very little to say, because he had never adopted any means of cultivation except horse and manual labour. Therefore he could not testify from personal experience of the value of the steam plough. But occasionally he looked over his neighbour's hedge and learnt a little. If he had a large occupation he should not have the least hesitation in adopting the steam plough. Mr. Richardson had, he thought, given them a capital lecture, and during its delivery he had made a few memoranda. The first note he had made was the cultivation of strong land. Now he had farmed strong land for 28 years, and he had no doubt of its being thoroughly adapted for steam cultivation. In some cases steam cultivation would, he considered, pay over and over again. In some instances a crust was formed on the ground, becoming an obstruction to the water going to the drains under. This, with other matters, had to be well considered. He pointed out that in chalky subsoils deep ploughing would never pay; that chalk at the top brought up by ploughing was no good and never would answer. He believed a great quantity of our light soils was rendered more productive by treading. He had not one word to say against steam cultivation. He expressed an opinion that there was a deal to learn before steam cultivation was generally adopted. He, however, set it down as for the good of agriculture and the good of the community generally. Regarding the cost of steam cultivation, he thought that the 5s. estimated by Mr. Richardson was the average on 2,000 acres. He, however,

could not speak positively on the subject. He was not experienced in the use of the steam plough. He had been a farmer a great many years, and he supposed that to the end of his days he should continue to use a two-horse plough, a man holding after. At the same time he had a son who had gone in for steam cultivation, and was now cultivating all his land by steam. If he were young and had sufficient capital he should probably fall into the same view as his son.

Mr. RICHARDSON pointed out that he had distinctly stated in the outset of his address that he did not intend to treat on the mechanical part of the subject. He was aware that there were many opinions respecting the different adaptations of machinery necessary to encounter the varied nature of the soils. He had come there to try to show them the beneficial and economical results of steam cultivation. When he told them that he had spent upwards of £20,000 in introducing steam cultivation before he had a penny in return, he thought they would say either he was a fool or ought to have learnt something. He was happy to say that what he had done had

fallen on a good soil, and was now returning a handsome income. In Berkshire he had introduced in one year three sets of ploughing tackle, on one single farm, where 1,100 acres had been worked. Respecting the 3s. per acre, he had never said the work could have been done for that. Was it at all likely that he would have said so? If he had done so they would have replied, he should think, by saying "Bring us down twenty sets and work our land directly." He begged them not to go away with the erroneous impression that he would work their land for 3s. per acre. He submitted that £2,000 laid out in steam ploughing would be well laid out, that the purchaser would be reimbursed 10 to 15 per cent. more than he would ever get by farming. He also submitted that he could work the steam plough nine months out of the twelve. At a trial at Bury St. Edmunds five acres and one rood was done in an hour. Meeting the difficulty of being able to get the steam plough when they wanted it, he recommended the contract system, which he looked upon as perfectly safe for the farmer.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

MONTHLY COUNCIL, Wednesday, February 2.—President: Lord Walsingham, Vice-President, in the chair; the Earl of Lichfield, the Earl of Powis, Lord Chesham, Lord Tredegar, Lord Vernon, Sir Watkin Wynn, Bart., M.P., Mr. Barthropp, Mr. Booth, Mr. Bowly, Mr. Cantrell, Colonel Challoner, Mr. Davies, Mr. Dent, M.P., Mr. Druce, Mr. Edmunds, Mr. Brandreth Gibbs, Mr. Holland, Mr. Hornsby, Colonel Kingscote, M.P., Mr. Lawes, Mr. Leeds, Mr. Milward, Mr. Pain, Mr. Ransome, Mr. Rigden, Mr. Shuttleworth, Mr. Thompson, Mr. Torr, Mr. Webb, Mr. Whitehead, Mr. Jacob Wilson, and Dr. Voelcker.

The following members were elected:

Baillie, Lieut.-Col. Hugh Smith, Househill, Nairn, N.B.
Binney, Charles H., North Chesham, Sutton, Surrey
Blundell, J. H., Woodside, Laton
Botfield, Rev. W. B., Garnett, Decker Hill, Shifnal
Bull, J. H. W., Great Walford, Shipston-on-Stour
Burnham, W. H., Long Compton, Shipston-on-Stour
Carter, J. Quartly, Arborfield, Reading
Clarke, E. C., Manor Farm, Haddenham, Thame
Clifton, T. Henry, Lytham Hall, Lytham
Cockburn, George, Newcastle-on-Tyne
De Mornay, Alfred, Cold Harbour, Wallingford
Fair, Thomas, Westwood, Lytham
Fisher, E. Knapp, Market Harborough
Fisher, John, Wood House, Cross Hills
Ford, Sir Francis Colville, Bart., The Ridges, Hartfield, Tunbridge Wells
Fowler, Richard, Brompton Farm, Aylesbury
Fowler, William, Pauntley, Navent
Franklin, Thomas, Ascott, Wallingford
Franklin, W. Taylor, Ascott, Wallingford
Garrett, Richard, Carleton Hall, Saxmundham
Godwin, John, Troy Farm, Doddington, Oxon
Hall, Marriott, Thorpe Salvin, Woking
Higgs, John Birch, Brewood, Penkridge
Jackson, James, 6, Chapel Street, Preston
Lane, John, Winalow Hall, Bucks
Latham, Thomas, Wittenham, Abingdon
Little, Herbert J., Thorpeclands, Northampton
Manley, Augustus East, Manley Hall, Lichfield
Marshall, James, Low Horton, Cramlington
Marsland, William, Baguley Hall, Northenden
Masters, Albert Edward, Nevenson Hall, Chelmsford
Mitchell, John, The Beacon, Penkridge
Owen, Griffith H., Ynwlle, Tremadoc
Parr, John, Cropwell Butler, Bingham
Phelps, E. G. Hart, Bidley Parsonage, Wrotham

Roberts, Joseph, Caswell House, Witney
Singleton, John, Poulton Le Fylde
Smith, Samuel, Somerton, Deddington, Oxon
Stilgoe, Nathaniel, Manor Farm, Andebury, Banbury
Thomas, William, Penfields, Wolverhampton
Tomlin, J. R., Stoke Field, Newark
Tompkins, John, Town Farm, Irvinhoe, Tring
Tovey, Joseph, Cirencester
Turner, John, The Grange, Ulceby
Walton, H. L., Birmingham, Shipston-on-Stour
Wharton, G. Livingston, Grovehill, Beverley
Wheeler, John, Long Compton, Shipston-on-Stour
Whittall, Thomas, Bailey Inon, Llandrindod Wells
Wingfield, John H. L., Tickenote, Stamford
Woodcock, Richard, Wolverhampton
Wyatt, Robert, Acton Hill, Stafford.

FINANCES.—Colonel Kingscote, M.P., presented the report, from which it appeared that the Secretary's receipts during the past two months had been examined by the committee, and by Messrs. Quilter, Ball, and Co., the Society's accountants, and were found correct. The balance in the hands of the bankers on January 31 was £1,748 4s. 11d. The balance-sheet for the quarter ended December 31, 1869, and the statement of subscriptions and arrears, were laid upon the table; the amount of arrears then due being £1,150. One hundred and fifty-nine members have given notice during the past year of their withdrawal from the Society.

The committee reported that Mr. Wilkes, the junior clerk, wished to retire, owing to his health failing, and his having an engagement better adapted to him. They wished to express their entire satisfaction with Mr. Wilkes during the nine years that he has been in the employment of the Society; and they recommended that Mr. Hine, who has been employed as temporary clerk for some years past, should be appointed to succeed Mr. Wilkes. The Manchester country meeting account was laid before the Council, by which it appeared that the receipts exceeded the expenditure by £9,152 11s. 3d. It was recommended that the name of Mr. Davies be added to the list of the committee. This report having been adopted, a conversation arose with regard to the award made against the Manchester local committee for compensation to the tenant of the trial-fields; and Colonel

Challoner gave notice that, at the next Monthly Council, he would move—"That a sum of £500 be given to the Manchester local committee in aid of the extra expenditure occasioned by the compensation awarded to the tenant of the trial ground."

JOURNAL.—Mr. Thompson (chairman) reported that the committee recommended the publication of the February Number of the Journal as soon as possible, without waiting for the usual statistics. They also recommended that the annual lists of the Council and committee shall in future be circulated in March instead of February.—This report was adopted.

GENERAL OXFORD.—Lord Walsingham (chairman) reported the recommendation of the committee that the Oxford Stock Prize-sheet be finally closed.—This report was adopted.

EDUCATION.—Mr. Holland (chairman) laid before the Council the syllabus of subjects for examination in agricultural chemistry, botany, geology, land-surveying, and mechanics; and he reported that the committee recommended them being printed and circulated amongst candidates, together with a syllabus of subjects in general chemistry and in anatomy and animal physiology.—This report was adopted.

CHEMICAL.—Mr. Dent, M.P., reported that the committee had before them the correspondence between Messrs. Dobell and the consulting chemist and secretary of the Society. They decline to enter into the correspondence between Messrs. Dobell and Howden. They are satisfied that the sample of guano sent to Dr. Voelcker was described to him as "Guano genuine as imported," and that Dr. Voelcker's analysis of the manure was correct. It is no part of Dr. Voelcker's duty to inquire from the seller the price of an article submitted to him for analysis, but to give a correct analysis; and in cases where the constituents of such articles appear to be agriculturally valueless, this committee recommend the publication of the analysis to be continued. The object of publishing these analyses is not merely to show that the dealer is charging more than the value of the article sold, but to warn the purchaser against buying at any price an article which is of only a nominal agricultural value.

Professor Voelcker reported on a correspondence from the Foreign Office on the subject of guano now being imported from the Guanapé Islands, that he had made analyses of five different samples from bulk, which vary considerably in composition, and generally resemble Peruvian guano damaged by water. The variation in samples is so considerable that purchasers should be careful not to buy this guano without a guaranteed analysis. This is corroborated by the analysis furnished in the official report forwarded by the Board of Trade to the Society, where, out of 13 samples, the amount of ammonia varies from 3.8 to 14.1 per cent.*

It was moved by Mr. Milward, and seconded by Mr. Jacob Wilson, "That Messrs. Bowly and Sanday be paid

for their services as judges at Manchester, in accordance with the letters of the Secretary to them." After a discussion on the question whether there existed any rule to the contrary, which was decided in the negative, the motion was put from the chair, and carried unanimously.

Lord Vernon having moved the resolution of which he had given notice, it was seconded by Mr. Milward, and a rider was added, at the suggestion of Mr. Thompson. A discussion then arose as to whether judges were paid for their time, or only a sufficient sum to cover their expenses; and it was stated by Colonel Challoner and Lord Vernon that cases had arisen where members of Council had resigned their seats in consequence of their inability to perform the duties of the office of judge to which they had been elected without the usual payment. Lord Vernon, Colonel Challoner, and Lord Walsingham also commented on the desirability of obtaining the aid of the most competent men, whether they are on the Council or not. Ultimately the resolution, as amended, was carried, with one dissentient, as follows:—"That judges who are members of Council may be paid as other judges, by special vote of Council after a month's notice."

The Earl of Lichfield called the attention of the Council to the inconvenience arising out of the conditions of the charter fixing the date and place of holding the general meeting, and excluding from the Society's meetings the discussion of all subjects having reference to measures pending, or to be brought forward, in either House of Parliament. He sketched the history of the last reference of this subject to a committee; but as that committee had never reported, he wished to refer the matter once more to a committee for consideration. He also stated that many subjects enumerated in the existing charter as objects for which the Society was established, could not be discussed without reference to politics and to necessary legislation. Mr. Thompson stated, that although the time fixed by the charter for holding the annual meeting was very inconvenient, he did not think that alone would justify the expense of obtaining a new charter. He also drew a distinction between the functions of the Legislature in passing laws, and those of the Society in dealing with questions after those laws had been made. After a further discussion, in which Col. Challoner, Mr. Holland, and Mr. Dent, M.P., took part, the question as to the date of the annual meeting was, on the suggestion of Mr. Thompson, referred to the committee for the revision of the bye-laws.

It was moved by Mr. D. R. Davies, seconded by Mr. Jacob Wilson, and carried unanimously, that Sir Watkin W. Wynne be elected steward of live stock. Letters were received from the authorities of Shrewsbury, Stafford, and Wolverhampton, announcing their intention of inviting the Society to hold its country meeting for 1871 at their respective towns; and the Secretary was instructed to forward the usual documents to the mayors of the competing localities. Mr. Jacob Wilson gave notice that at the next Monthly Council he would move—"That the committee for the recommendation of judges be appointed at the March Council, that this committee shall sit in April, and that the absolute appointment of judges shall take place at the May Council."

Letters were read from the Secretary of State for Foreign Affairs, enclosing reports on the cultivation of Flax, received from her Majesty's Representatives at St. Petersburg, Brussels, and the Hague; and from the Secretary of the Board of Trade, enclosing a document entitled, "Notes on a new method of cultivating and in-

* The detailed official report is appended, having been forwarded to the Society by the Secretary of the Board of Trade, with a request that it should be made public.

creasing the productiveness of the soil." Thanks were ordered for these communications.

The following is the official report on the guano of the Guanapé Islands :

"The guano of the Guanapé Islands partakes of a composition varying much according to locality and depth. In general, on the North as well as on the South Island, the superficial strata exposed to the vicissitudes of the atmosphere are deficient in soluble salts, and consequently in ammonia, augmenting the proportion of phosphate of lime. In the lower strata, on the contrary, the quantity of ammoniacal salts augments, thus diminishing the phosphate of lime. It is probable that by the action which has dissolved the ammoniacal salts of the superficial strata, it may have penetrated by infiltration into the strata underneath, thus increasing the richness of the latter; so that in the end the ammonia, which forms the most valuable principle of guano, is not lost, being concentrated, as it is, in the deeper layers of guano. In the Southern Island the change is manifested in a manner still more evident, as of the three samples that have been analysed the most superficial contains only 7.562 per cent. of ammonia, and in the sample extracted from a greater depth the ammonia contained in 100 parts of guano rises to 18.020—a greater quantity than what is contained in the best guano of the Chincha Islands. This last is formed almost entirely (95,000) of ammoniacal salts soluble in water, consisting in greater part of oxalate and urate of ammonia, and should not be considered as a variety of guano, but as a combination of the soluble parts of the guano which appear to have been separated by the action of water. This sample, although possessing a strong ammoniacal smell equal to the guanoes of the best quality, differs nevertheless through its other physical characters, presenting itself under the form of a pulverulate homogeneous matter of a more pronounced yellow colour than that of common guano, and with a crystalline structure only to be perceived through the medium of a microscope. If the bed of this material is in reality 7 feet in thickness, according to Mr. Harris, who extracted the samples, it appears to me that a greater advantage could be obtained by selling this material to certain manufacturers of chemical productions as liquid ammonia; exalate of ammonia or uric acid could be extracted with much facility for the manufacture of the colouring matter called 'murexide.' As this sample is very rich in ammonia, and very poor, on the contrary, in phosphate of lime—containing less than 5:100 of this salt—it could not be employed with advantage in agriculture, one of the principal elements being wanting for plants; and in case it could not be sold, as was suggested, to manufacturers of chemical productions, it could be utilised very well by mixing it with the guano from the Lobos Islands, which in general contain a strong proportion of phosphate of lime, and *per contra*, is very poor in ammonia. By mixing the material in question this guano would be improved, and would cause the value of the guano of the Lobos Islands to be enhanced, equalising it with the guano of good quality. Some of the samples of guano from Guanapé subjected to analysis contain a strong proportion of water, so that when the guano is pounded in a mortar with the object of rendering it more homogeneous before proceeding to analyse it, it collects and forms a really sticky paste. At first sight it would be said that this guano had been wetted; but recognizing the great hygrometric power which guano has, and knowing that the sample in question had been extracted in winter time, when the atmosphere of the coast is almost entirely saturated with water, the great quantity of moisture which it contains is easily explained. I myself at another period made some experiments for studying the hygrometric power of guano, by keeping exposed to the open air a certain weighed quantity of guano, and I have beheld it increase or diminish in weight according as the weather was more or less dry. The element which is of most value in guano, after the ammonia, is phosphoric acid; but, as is known, almost the whole of the phosphoric acid contained in the guano is found combined with lime, forming a phosphate of lime, tribasic, not very soluble in water, and consequently absorbed with difficulty by plants. Various chemists who busy themselves with the study of guano have thought, and with justice, that by rendering the phosphoric acid contained in guano more soluble in water, and consequently easier to be absorbed by plants, the value of this mate-

rial would be augmented. So for many years Mr. Nesbit advised mixing guano with sulphuric acid, the which, by uniting itself with part of the lime, leaves free a part of phosphoric acid, which forms with the other portion of the lime a phosphatic acid, easily soluble in water. Mr. Richardson put this theory in practice, and even asked for a patent for the transformation and amelioration of guano. Now, as not the whole quantity of phosphoric acid contained in guano is found in a state insoluble, under the form of tri-phosphate of lime, I have deemed it necessary in the analysis which I have made to make known likewise the proportion of soluble phosphoric acid which the guano of Guanapé contains, as will be seen by the table giving the result of the analysis."

AMMONIA CONTAINED IN 100 PARTS OF GUANO.....	NUMBER OF THE SAMPLES.	NORTH ISLAND.										SOUTH ISLAND.

ANALYSIS OF THE GUANAPE GUANO.

THE BREEDING AND FEEDING OF LAMBS.

At the first monthly meeting of the Lavenham Farmers' Club for the present year, Mr. GREENE, M.P., was announced to read a paper on this subject.

Mr. HITCHCOCK, the Chairman, said there were not less than thirty million of sheep in this country, and at 30s. each they represented a capital of £45,000,000. But it was not merely their money value which was of importance, for sheep formed an important element in the food of the nation, and their object should be to increase the number. The high price of mutton, occasioned partly by the cattle-plague and partly by the drought of 1868, had given dissatisfaction to many people, and they were now turning their attention to the importation of carcases from Australia and South America. Whether or not that would answer remained to be proved, but he hoped they would not be overwhelmed with an avalanche of mutton of Professor Gamgee's curing. They were now suffering from a plethora of wheat, and if they were to be overwhelmed with a supply of meat also they might soon be in the position of the Irishman who, when complaining of the price of potatoes in England, and saying that he could buy as many in Ireland for sixpence as he could here for a shilling, was asked why he did not stay in Ireland, and he replied, "There were no sixpences there."

Mr. GREENE said: First and foremost is the selection of your ewe. We have arrived at a time when, in this country, we have lost our distinctive breed of sheep. Many here must remember when on most farms there was a flock of South-down ewes; but as the price of wool and meat advanced, farmers turned their attention to getting a sheep that would clip more wool and breed a larger lamb; hence they crossed their Downs with a long-wool tup and were handsomely repaid in their first cross. But as their Down ewes wore out they commenced breeding from the half-bred ewe, and I am inclined to think if they had continued judiciously to tup with half-bred tups, which half-bred having either Sussex Down, or Hampshire Down on one side, they would have been more successful. I was favoured by that well-known breeder of sheep Mr. Lagar, of Ingham, with a sight of his flock of ewes, bred as I have described, and very even well-formed ewes they are, combining both mutton and wool. His foundation was South-down ewes. I am of opinion that although the black-faced ewe is a valuable animal for one cross, yet it is not desirable to breed from her produce, she not being a pure-bred animal herself—hence it is we see so many long-legged, slow-grazing lambs. I myself have bred from several different classes of ewes, and have found no animal gives me so good a lamb as a well-bred Hampshire ewe crossed with a Lincoln or one of Aylmer's tups; but from the necessity of frequently purchasing the ewes at a high price, I am about to test the merits of the Shropshire sheep, and for that purpose have selected some of the best bred ewes and tups I could find, combining the aptitude of the fattening of the Down with more size, and I expect to be able to carry, on the same food, more sheep than of the half-bred kind. Should this be the case, I shall be able to keep up my own flock without going to market. In my remarks on sheep it must be borne in mind that my experience applies chiefly to light land suitable to sheep. I believe the dry seasons we have had for two or three years previous to this has led many heavy land farmers to attempt breeding sheep, and unless they have a fair acreage of pasture saved up after the hay is cut to winter upon, they cannot breed to a profit on a large scale, they being unable to keep their sheep on the land in winter. I have observed that ewes on cold land require much more expensive feeding than on light—on heavy land I should graze in summer. Having judiciously selected the ewe and tup, I am in favour of putting the tups with the ewes in the third week in August, or first week in September, so as to have most of your lambs born in February. My reason is, that an early lamb is always a superior animal to those that come later, and I am about to state that which at first sight will, I know, be questioned, and that is—you are better off for food at that season than when you lamb in March; as every gentleman in

this room will allow that in February and the early part of March his white turnips are better than later on, and, moreover, they ought to be fed off, and the barley sown early in March. You will, very properly, think—well, what is now to be done? I will tell you. No man is worthy to be called a flockmaster whose thoughts are not always looking forward for months as to how his sheep are to be fed. I will, therefore, hark back to my ewes at tugging time. Having fixed the third week in August or first week in September, and having previously got my ewes into good condition, which I think very important, as I find a ewe in high condition in the autumn is wintered very much cheaper and with less loss than a poor one, I then, if possible, divide them into lots of from fifty to eighty, and prefer having only one tup with them at a time. I tup on early sown turnips, or coleseed and young layers, according to the seasons. My ewes having been tugged, I have a bit of mustard and a run on some old grass, and as soon as my mangold is off I fold the land, having two rows of swedes and one row of cabbages to every ten rows put in with my mangold, and this with a run out for an hour or two on grass and a little chaff carries me on until lambing time. One thing I have found very important is to avoid allowing them to eat food with the frost upon it. I believe food of that kind is very injurious to ewes in lamb. I may say, in passing, I am against stuffing ewes with a lot of straw chaff. My twelve score ewes have four bags, of eight bushels each, daily of cut pea straw this year; and when that is done I shall mix one-third hay with straw. I put a bushel of bran into each bag; and my ewes are looking well. The mangold land will be finished about a fortnight before the ewes lamb, as I like to put them on white turnips for a short time, it helps their milk. I always now plant a few acres of cabbages in June ready for lambing, as they are invaluable to put in the pens when ewes first lamb, and to strew about under hedgerows for the ewes until the lambs are strong enough to go to turnips. I give my ewes artificial food—either cake, malt dust, or oats—for the first few weeks after lambing, at a cost of 3d. or 4d. per head. When my ewes leave the turnips, I have provided after harvest on a wheat stubble a mixture of rye, wheat, tares, coleseed, and green round turnips; from that I go to rye, and then on to a bit of rye-grass sown in the wheat; and this, with a very few acres of layer, say 10—as I mow all I can—carries my sheep on until after the feed is ready. Now, having bred your lambs right, comes the point, how are they to be managed in the most profitable manner? I believe by never allowing them to go back so as to lose their lamb fat. My shepherd teaches my lambs to feed as soon as possible, with a little bran, crushed oats, and linseed cake for a few weeks; then cotton and linseed; and I spend about 1½d. to 2d. per head a week upon them until September or October, when I increase it to 3d. until the end of December, and then for a few weeks up to 6d. per head for artificial food, seldom exceeding that sum. The lambs, of course, run forward through lamb hurdles, and I do not cut them young, but sear them in May or the first week in June, when I clip the ewes and take off the lambs. I have also tried the experiment of clipping lambs in June, and if you wish to force your lambs to an early market in January, I believe it will thoroughly answer. I find the clipped ones grow faster on the same food. I tried a few lambs, and when I sold my lambs to a gentleman I now see in the room, I think he will bear me out that they were certainly not the worst among them. The lambs being off, the ewes are then folded on the layers, and I generally grow a bit of coleseed as a change of food, which is very essential. I need not remark I am very careful not to put the lambs on layers that have been mucked or folded, as that will surely kill or injure them. Great care is required that the lambs have always water by them in the summer. If you depend upon driving them to water, they may miss drinking one day, and the next will take more than is good for them. They should also have rock salt. It is important when the sun is hot that the lambs should be put into the shade in the middle of the day. Besides the advantage to your land, and to your lambs generally of giving them artificial

food, you make a good price of your refuse. I sold three score of my refuse, not leaving one behind, this last September, at 24s. each, and I am sure, had they had no assistance, they would not have fetched more than 16s., so that in that lot alone I had £24 for cake. Layers, mustards, &c., being done, I begin with a few acres of white turnips, and then, about the 1st December, get on to swedes, having them clamped on the land: they are cut by Gardner's cutter, and I never give swedes whole. Judgment is required, on every change of food, not to overdo your lambs. I always have a double fold and double set of troughs, so that the lambs are shut back and all the food put in the troughs first, which gives every lamb a fair chance, and prevents the strong ones pushing the weaker ones aside. I think ten score is the outside number that ought to be in one fold. In the middle of February I sell my hoggets, many of them fat; some one buys them to finish, and, as "the proof of the pudding is in the eating," I shall probably sell them to a gentleman I see in this room, and you will most likely see them in Bury market and judge for yourselves. I do not see how a farmer is to pay his rent and expenses off a light land farm unless the gross price of his lambs come up to the rent. I believe the advantage both in corn, meat and money is in favour of keeping your lambs and sheep well. I never sell my ewes and old ewes at less than from 35s. to 42s.—fresh, not fat—and take lambs, treated as I have described, on 1st August to be worth 32s. each. Spend 3d. per head per week for artificial food up to 21st December (20 weeks), 5s. per head; from 21st December to 21st February is 9 weeks at 6d., 4s. 6d., which brings the cost price up to 41s. 6d., and you may reckon on the average of years they will be worth 50s., leaving £8 10s. per score for turnips, &c., the breeder having been well paid on the value of his lambs on the 1st August. If I was going to clip my hoggets, and feed them off in summer, I should treat them as described, but at less expense for artificial food; but always bear in mind with every animal for meat, never to lose its young fat. Every pound of meat lost, costs money to replace—a loss of 1lb. at 9d., costs 8d. to put on, which makes 1s. 6d. I must say on riding about the country I have observed in many instances a great want of management in sheep; but by keeping a strict eye to their well-doing, they must pay. Mind, I am against extravagance in feeding animals. I believe much money is wasted in giving too much artificial food to both sheep and bullocks. They require a diversity of food, and can only assimilate profitably a certain quantity; but the more you mix cake with other descriptions of grain, in my opinion, the better; and though you may say I am recommending my own wares, a few grains will be found to assist lambs very much. Times are now not very cheery for farmers. The dry summer of 1868 and the light crop and low price of wheat in 1869 will prove trying to many; but put on a good heart, look well to your stock and land—both are grateful for good treatment. I have had 40 years' experience in business, and have witnessed frequent changes of depression and prosperity; but have generally found the persevering succeed. In conclusion, I can only say plough and sow, tend well your stock, and look with humble faith to Him who always blesses honest labour. If I have only caused by these remarks further thought on the subject amongst you, my brother farmers, if I may call myself one, I shall feel amply repaid. There was one little remark he had forgotten. He had a double set of troughs, and he did not put turnips in the same trough with the cake. His sheep of course always had a little cake and chaff the first thing in the morning and the last thing at night, as it was very important they should have something of a dry nature before going to the cold food. He was particularly careful, if his sheep were on turnips, not to let them eat turnips till the frost was off them in the morning, as he had found frosted food very injurious.

The CHAIRMAN next called upon Mr. Badham, and invited him to make some remarks upon Mr. Greene's paper.

Mr. BADHAM said that he had not paid so much attention to sheep as he had to some other animals, and he thought it was very likely he had been a loser by it—he had no doubt of it. He was foolish enough to stick to the little Southdowns. He did not know that much advantage was gained by it except that he kept good animals, and always got good mutton. He cordially agreed with what Mr. Greene had said about clean troughs, and also as to guarding against frost, which did great mischief, especially to sheep.

Mr. BIDDLELL said his experience was very much like Mr. Badham's—in favour of the Southdown ewe. Some years back he had the misfortune to have his stock afflicted with the cattle-plague, and by necessity he was compelled to turn his attention to sheep. He enlarged his flock so that he kept a little more than an ewe to the acre, viz., 20 score on 380 acres of land. He was highly gratified at the result, and some persons went so far as to say that his sheep more than made up what he had suffered from the cattle-plague, but he was not at all sure they were right in that. It, however, led him to think what he could do with keeping ewes on heavy land. He had the advantage of a good deal of pasture, nearly all of which he used to mow, but he thought it was quite possible to keep sheep with profit on heavy land. Ever since what he might call the discovery of beetroot (for it had been introduced within the memory of the present generation) they had been placed in a much more favourable position in reference to keeping sheep than formerly. Till then they had nothing to give their sheep in April and May, for turnips would not keep so long, and if they had had to depend upon hay he was sure the balance would have been "over the left," for he did not think they could find a more expensive thing to feed sheep upon. But since they had had beetroot they could dispense with hay.

Mr. GREENE: How do you keep sheep on heavy land in wet weather?

Mr. BIDDLELL said when he could not keep them on the land he took them off and put them in the yard. He suggested that if they could grow some rows of turnips or cabbages with their beet, and so get some sheep feed on the land, the land would be greatly improved. With regard to the time of tupping, if the object was to sell the lambs, no doubt the sooner they were dropped the better; but if they intended keeping them, he doubted whether it was advisable to tup so early as Mr. Greene had stated. Though they came early they would be found to have very large appetites when food began to run short.

Mr. GREENE: You ought not to be short of food in April.

Mr. BIDDLELL said sometimes May was a very backward month.

Mr. GREENE said there was the rye, and he had never known the May in which he had not had a good bite for sheep on the rye-grass.

Mr. BIDDLELL said he remembered when there was none, but at the same time he admitted that that was an exceptional year. With regard to artificial food, he quite agreed with Mr. Greene that while mutton sold as it had done the last few years, they must not grudge 5s. a score per week for food of that description, and he believed they would be amply repaid; at the same time he had found a very nice balance-sheet without such assistance when food had been plentiful. With respect to layers, he considered that on heavy land they were the most expensive food they had. His practice had been to have very little layer, but to get a piece of rye-grass early, and then he could put them on to a meadow; or if he put in coleworts in May he got a very good crop in July and August; and he was persuaded that with attention they might be got by that time on heavy land. Some people got two crops of colewort, and if they could not do that they might get mustard, which was a good preparation for wheat, and between the two he thought they would have much better feed than by feeding on layers. With regard to clipping lambs, his experience was very limited. He never clipped but two, one of which died, and the other was as near death as possible. After they were shorn there came some scalding hot weather, and the sun took such an effect upon their skins as to make them peel. At the same time, he had fancied that some of his long-wooled sheep were greatly incommoded by having to carry their wool till March. As to cutting turnips, he was an advocate for allowing the sheep to cut their own food, provided they were white turnips. Swedes required cutting, and he thought all turnips should be cut after the animals' teeth began to loosen. He quite endorsed Mr. Greene's opinion that the sheep ought to pay the rent on a light land farm, and he was of opinion that, even in that locality, they might do more towards making the sheep pay the rent than they now did, and he strongly recommended the members of the Club to try.

Mr. BIDDLELL observed that Mr. Catchpole kept a good many sheep on heavy land, and asked for his experience.

Mr. CATCHPOLE said it was true he kept several on heavy

had, but he got them off it as soon as he could. He thought, however, they might be kept with good management.

Mr. EDGAR thought they might keep more sheep on heavy land than they had hitherto done. Mr. Biddell said he remembered one year when rye-grass did not come in May; but he (Mr. Edgar) never knew the year when there was not a good feed on rye-grass on heavy land in the third week in April, and, he thought there was a little more "fire" wanted under the grass Mr. Biddell referred to.

Mr. TALBOT said if they were sheep breeders (as they must be upon light land) he thought it was of the greatest importance to have the true-bred animals on both sides; and with regard to those for grazing purposes he should certainly say take the first cross. He was induced some few years ago by the representations of a few of those whom he considered his friends, to go in for true-bred animals, and he purchased some of the black-faced improved Suffolks. He purchased them of a well-known breeder, Mr. Dobito, and if he had stuck to those sheep he should soon have been ruined; he never in his life saw sheep with such appetites. He was very glad to get rid of them, and he certainly did not think they were the sort for the farmer to live by. The mutton might suit the epicure, but it was a little too rich for the farmer. As to keeping sheep on heavy land, where could they have been put during such weather as had been experienced during the last two or three months? They could not have sheds to keep them in the dry, and if they had been put on pastures, they would be ruined. The Suffolk pastures were not particularly good, nor particularly well farmed; but if ever so well farmed, the grass would be materially injured in an unkindly spring by sheep being put upon them. The only farm he knew in that neighbourhood on which the pastures did not appear to be injured by keeping sheep upon them was Mr. Hustler's, at Cockfield; but there it was well known were extremely good pastures, and that was quite quite an isolated case. With regard to the supply of food in the spring, if they were to carry out what had been said by Mr. Greene, and save up all their pasture in the autumn, ready for the spring, he was afraid they would not keep so much stock. They must provide certain food to keep their sheep in the winter and spring, but every practical farmer would agree with him that it was impossible to spare all their pastures for that particular purpose; if so they must very materially reduce the number of animals kept on the farm, and that he did not think was altogether the thing in the present day. As Mr. Biddell had observed, if there was anything of a paying nature connected with farming, it was sheep, and to these they must turn their attention. As far as corn was concerned, and especially wheat, they must never expect a very high average for it again; they had the whole world to go to, and even at the present price, 41s. a quarter, large quantities were constantly arriving. Therefore it behoved every tenant farmer to keep the greatest number of sheep he could, and that could only be done by using a certain amount of artificial food with the products of the farm, for there was a vast proportion of heavy land that would not graze sheep without food of some other kind. Grains might be very good, though he did not recommend them, and if he used them he should not buy them at Mr. Greene's, as he did not believe in the grains of A.K.

Mr. HUSTLER could not agree with Mr. Biddell as to the feeding on layers, and was inclined to look upon this as one of their best pieces of farming upon heavy land. If the land was good they got a capital crop; and where did animals do better than on a good layer? On a poor heavy land farm they did not get enough to mow; and what could they do better than feed it with sheep? He thought they might safely calculate on a good crop of wheat if they fed off their layers, more especially if they gave the sheep artificial food as well. He quite agreed that they might keep more sheep than they now did on heavy land by laying a little forward, and preparing for the spring; and as soon as he got his layer he felt that he could carry his sheep on through the year.

Mr. VINCE said he had been a heavy-land farmer all his life, but he was quite an amateur in sheep-breeding. He, however, had no doubt that if all light-land farmers took a lesson from Mr. Greene's paper they would not go much amiss. He believed they might keep more sheep than they now did by looking forward, and growing a little bit of rye grass and a bit of turnips and so on. He had always found sheep more profitable than many parts of farming, and should certainly

endeavour in future to keep more than he had hitherto done. If they kept only a small stock of breeding sheep they might buy in some hoggets early in the spring, and he believed they might improve their land as well as make the sheep pay.

Mr. HAWKINS said: Being a heavy land district, that locality was not much adapted for breeding sheep; but he was very fond of them, and was satisfied that if he dispensed with sheep he should have to shut up, for were it not for his sheep he did not believe he should have any profit on his stock. He generally set seven score of ewes, and bred fat lambs; he got his ewes in as good condition as he could, and kept the lambs as high as possible. To show them that he was not far wrong, he might state that his lambs generally brought him 35s. to 37s. each in the month of July. He felt quite sure that heavy land farms might be improved by keeping an increased number of sheep, and when they looked at the price mutton had made of late, he felt sure it paid them better than any other stock they could graze. His being a heavy land farm, he could not fold upon the land; but he found no difficulty in keeping his ewes and rearing and fattening his lambs. The only difficulty was to get the money to buy the food, but he grew everything except cake. He had found that the lambs obtained more benefit from giving the ewes cake than from giving it to the lambs themselves. He always used Mr. Aylmer's sheep, which produced most beautiful lambs. Sheep, he was convinced, were the mainstay of a light land occupation, and half the mainstay of a heavy land farm.

Mr. BIDDELL said Mr. Hustler had asked what he was to do with his layer if he did not feed it; but he might reply that there was no necessity to have one at all. He was sure if Mr. Hustler would keep an account of how many sheep he could keep on a layer, he would find that it would not pay him. He preferred himself coleworts, with mustard after. He might say when he experimented in clipping lambs it was in August, but Mr. Greene clipped in June. His were tup lambs, and they were ill because the sun got on their backs. Perhaps if they had been in the shade they might have got on better.

Mr. GREENE, in replying, said there were two things he liked—a good horse and a good sheep; very opposite animals, perhaps. To have given them an address upon the breeding of horses—well-bred hunters—would have been speaking Greek to them, so he had chosen his present subject. He did not want to dictate to them—to say that he was all right, and they were all wrong—he simply told them his own experience with sheep, which at any rate had brought him, if not profit, at least credit; for he thought he might say without egotism he had never had a bad lot yet. He only took up the subject some ten or twelve years ago, and then it was for his own amusement; and he thought when a man did that he must be able to afford it, for the profits would never blind him. He quite agreed with Mr. Biddell about the Southdowns, and he was inclined to think farmers deserted them too soon. Mr. Kersey Cooper, who would have been there that evening if he had been able, had often laughed at him because he had tried almost every description of sheep. He had now bought some Shropshires, and he had got his nearly like the Downs, but with more size. He thought if the Downs had the same chance as the half-breds, and they let them have the best food, farmers would be able to carry more sheep per acre. This, however, was speculation, for he had not tried it. On heavy land he was sure sheep would pay if they could only keep them about on the pastures, and in the yards at night, and have mangolds to give them. But that was a matter he must leave to heavy land farmers. With regard to clipping lambs, he was there only to tell them what he had done himself. He clipped only a few, neither the best nor the worst, and when he sold the lot he believed the clipped lambs were worth 7s. 6d. each more than the others in the lot. He would not recommend them to clip those they were going to keep, as at clipping time they would lose some wool—he did not know what amount. The lambs clipped about 3lbs. in May, and he should think on the average they would clip about 3lbs. The wool made about 9d. a pound; that would be 2s. Mr. Biddell's experience was with two; his was with three score, and he had not lost one. Last June, after clipping, there was some extraordinarily cold weather, and he lost three ewes, although they had cake, but the lambs did not appear to suffer, and he never lost one. He had not fed the clipped ones differently to the un-

clipped. He selected five of the largest and sent them to market, just to see what they were worth, and although he contended that they did not fetch within 4s. of what they were worth, they made 53s. 6d. each; they might judge they were pretty fair hoggets to fetch that, and yet they had not half-a-pound of cake a-day. He thought he should force his clipped lambs more than the others, and he believed they would bear it, and he should get them to market when mutton was dear. He wanted to impress upon them the importance of early tugging. He was speaking now of a light farm, because, as he had said before, he had never farmed heavy land, and he hoped he never should. He liked land over which he could ride without dirtying his horse or splashing his boots. He must recommend early lambing, and one failure was no proof against it. They failed in one thing, but in how many did

they succeed. If he farmed heavy land he should be inclined to follow Mr. Hawkins's plan, and fat both ewe and lamb every year. If they forced a ewe well they could do it, but they must put their hand in their pocket for without that they could do nothing. He believed February or March was the best time for lambing, and it suited the land best, too. He once passed a piece of land belonging to a man who did not spend much on his ewes, and he believed through not putting his hand in his pocket for some cake, that man lost three combes an acre of barley on twenty acres of land. Although he never let his lambs be without cake or bran, yet depend upon it, the cake to the ewe was the secret of making the lamb look well, and then, besides, if one of their ewes did not please them, they could sell her at a very good price. Still they must not be extravagant, for they would also lose by that.

THE SMITHFIELD CLUB.

At a meeting of the Council held Feb. 1, 1870, present: the Earl of Powis, President, in the chair; Lord Tredegar, Messrs. J. D. Allen, H. Aylmer, J. N. Beasley, C. S. Bigge, W. B. Canning, John Clayden, Samuel Druce, Thos. Duckham, J. Druce, J. H. Downing, W. Farthing, C. Howard, Jas. Howard, M.P., R. Leeds, H. Overman, Jno. Painter, Wm. Rigden, Wm. Torr, J. S. Turner, Thos. Twitchell, Brandreth Gibbs (Hon. Secretary).—the minutes of the last Council meeting were read and confirmed.

The Stewards reported on the cases referred to them as to the qualification of certain animals at the last show. The Hon. Secretary was requested to communicate with one of the exhibitors in reference thereto, and the reply to be laid before a Special Council, which the President was requested to order to be summoned in May.

Mr. R. J. Newton, of Campsfield, Woodstock, and Mr. Wm. Sanday, of Radcliffe-on-Trent, were elected Stewards of live stock for the ensuing three years.

Mr. Joseph Druce and Mr. Robert Leeds were re-appointed stewards of implements for this year.

The Council proceeded to revise the Prize Sheet for this year's show.

For Scotch horned classes it was determined to substitute the words "West Highland breed" and to establish distinct classes for "Other Scotch horned breed," viz.: Steers or oxen of any age, the prize of £10 and silver medal to the breeder; heifers and cows of any age, the prize of £10 and silver medal to the breeder.

It was resolved to establish a new class in each of the following divisions of sheep, viz.: Leicesters, Cotswolds, Lincolns, Southdowns, Hampshire, or Wiltshire, Shropshire, and Oxfordshire, for pens of 3 ewes above 3 years old, and that must have had a lamb; the prize of £10 and silver medal to the breeder.

It was resolved that the prizes two-year-old Southdowns be first prize £15, second £10; also, that the two-year-old class for Hampshire or Wiltshire Downs be discontinued; also, that in the two-year-old Oxfordshire class there be only one prize of £10; also, that the Ryeland, Cheviot, and Dorset divisions stand before the Mountain in the prize sheet.

The Champion Prize Plate of £100 for the best Beast in the Show.

The Champion Prize Plate of £50, for the best pen of Sheep in the Show, be again offered; but that the Champion Plate for the best single Sheep be discontinued.

In the condition of the silver cups, in the division for Shropshire, Oxfordshire, cross-bred, or any other breed not before specified, the words 1 year old be inserted so as to limit the competition to one year old Sheep, as already in the Southdown divisions.

That the Prizes in Extra Stock, Steers, or Oxen and Cows, or Heifers, be increased from 25 to £10.

That all the Silver Medals for single Sheep in Extra Stock be abolished; and, in lieu thereof, a Silver Cup, not exceeding

£25 in value, be given for the best wether in the following divisions:

1st. Leicesters, Cotswolds, Lincoln, and Kentish or other long wools.

2nd. Southdowns, Hampshire, or Wiltshire Downs.

3rd. Shropshire, Oxfordshire, cross-bred, or any other breed of Sheep not specified above.

Also, that a Silver Cup as above be given for the best single Pig in Extra Stock.

The wording of Rule 17 was amended.

It was resolved, That it be an instruction to the Judges Selection Committee not to appoint as judges any persons who will act as judges at the Birmingham Cattle Show the same year.

It was resolved:

1. That more stringent means be taken to prevent exhibitors and others entering the Hall previous to the day of judging, and that the attention of the directors of the Agricultural Hall Company be specially called to this point.
2. That the Club shall engage an official of its own in order to check any persons who may have got past the ordinary door-keeper hitherto appointed.
3. That the exhibitors and attendants in the implement galleries shall not have access to the ground floor, and that they shall have a distinct ticket, and be admitted by a doorway, so arranged as to allow of their going direct to the galleries.
4. That the stewards be empowered to incur such expenses as may be found necessary to carry out the above.

It was resolved, That the stewards be requested to revise the classification of breeds to be adjudicated upon by each set of judges.

The report of the Show-yard Committee as to proposed alterations was read, and referred to the same Committee to go into further detail to confer with the Directors of the Agricultural Hall Company, and to report to the Council to be held in May.

The Implement Committee was re-appointed for the present year, with the same powers as heretofore.

Letters were read and referred to the Implement Committee.

Also a memorial respecting the charges and arrangements for cattle conveyances was referred to the stewards.

The honorary secretary was requested to communicate with the Privy Council and the Metropolitan Board of Works, to see if the advertisement relative to the license for holding the Club's Show could not be curtailed by omitting apparently unnecessary details.

The following were elected members of the Club:—Wm. Webb Turner, of Chyngton, Seaford, Sussex; Mrs. Gerard Creswell, of Appleton Hall, Sandringham, Lynn, Norfolk.

A vote of thanks was passed to the Earl of Powis for his conduct in the chair.

THE MANAGEMENT OF THE SMITHFIELD CLUB SHOW.

It is seldom that any desire to reform abuses or correct mistakes has been set about with more vigorous determination than there has just been displayed by the management of the great Smithfield show. The tone of the whole sitting is eminently healthy and encouraging, as there is not a weak place but through which a new rail has been laid or a bit of fresh quick planted. On the opening day of the last show we protested against the same judges coming on from Birmingham to Islington, as we spoke to "the murmurs growing louder and louder as the awards still went the same way;" while we added that "Mr. Parrington at the best managed meeting we have, makes it an indispensable condition that any judge who accepts office at the Yorkshire in August should not have acted at the Royal Society's Show in July; and the Smithfield Club must do the same by the Birmingham." And the Smithfield Club has done so, for at the last Meeting it was resolved—the motion standing in the name of Lord Bridport—"that it be an instruction to the Judges' Selection Committee *not* to appoint as judges any persons who will act as judges at the Birmingham Cattle Show in the same year." Then, during the week we dwelt on the very unsatisfactory ruling in the Scotch-Horn breed or breeds, suggesting that the West Highlanders should be honoured with a class of their own. One of the late stewards, we believe, opposed this proposal, but the meeting adopted it, and "for Scotch Horned it was determined to substitute West Highland breed;" while distinct classes are to be established for "other Scotch horned breeds," which, save by crosses, we have not the slightest idea of ever seeing filled. Some alterations were made in the arrangement of the sheep classes, but no notice was taken of one of the judges' suggestion to do away with the light-weight Southdowns, nor of that from another as to "one of the judges in each class being a butcher;" about the very worst notion offered for many a long day. The complaint at the recent show was that the judges went a deal too often like butchers as it was; take, for instance, that very Highlander class, where they went clear away from character and style. A good heavy cross would generally promise to be the most valuable beast to the butcher; but, then, what are crosses without breeds? Horse-dealers, veterinary surgeons, butchers and salesmen should never be asked to act as judges at our great national meetings; for, like Mr. Weller, their "wisdom is limited."

But in the week after the Show, on the Monday, as this closed on the Friday, we were bold enough to go still further, and in the face of its "great success" and the "more money than ever taken at the doors," to declare that "nothing could be more unsatisfactory, not to say discreditable, than the condition into which the management of the Smithfield Club Cattle Show was gradually drifting." Of course we were quite prepared to hear, as we did hear, that this was finding fault merely for the sake of fault-finding, and so forth; although, nevertheless, we went on to demonstrate how very lax the system was becoming; how some exhibitors were let in and others were kept out; how the Hall Company was feeding up its own prize reporter; and how other "gentlemen of the Press" were quite content to pass for implement makers' assistants.

And at the February Meeting the following resolutions were put and carried, on the motion of Mr. Henry Overman, and with the hearty concurrence of the director of the show: "1. That more stringent means be taken to prevent exhibitors and others entering the Hall previous to the day of judging, and that the attention of the directors of the Agricultural Hall Company be specially called to this point. 2. That the Club shall engage an official of its own in order to check any persons who may have got past the ordinary door-keeper hitherto appointed. 3. That the exhibitors and attendants in the implement galleries shall not have access to the ground floor, and that they shall have a distinct ticket, and be admitted by a doorway, so arranged as to allow of their going direct to the galleries. 4. That the stewards be empowered to incur such expense as may be found necessary to carry out the above." The point of these resolutions, as we take it, centres on the Club providing an official check of *its own* and on the stewards having full power, or rather *sole* power. The Agricultural Hall Company has, or should have, no more share in the management at Islington than Mr. Boulnois had in Baker-street; as, in fact, the Club and the Company cannot be kept too distinct from each other. And yet on the very title-page of the Club catalogue we see officially paraded the names in full of the chairman and the secretary—not of the Club, but of the Company! where they have about as much right to be as on the cover of the catalogue of the Royal Academy. Again, running across every page of the Smithfield Club catalogue, we have in large lettering the announcement of the Islington Horse Show, just as if it were one and the same concern! Let the Islington Hall Horse Show be advertised, and let the chairman and secretary of the Islington Hall Company advertise themselves by all manner of means in the proper place, which we imagine to be the general advertising sheet; but unless the Smithfield Club is to be handed over bodily to the Hall Company, it certainly does seem that the names of the president and honorary secretary of the Club should, if any, grace the title page, as that for all sorts of reasons it is very desirable that the national cattle show should not be in any way associated with the Christmas circus, the summer Horse Show, or any other mountebank performances which may take place at other times within the Hall. As little "liberties" of this kind commonly lead on to more serious encroachments they cannot too soon be corrected.

THE ROYAL AGRICULTURAL BENEVOLENT INSTITUTION.—At the monthly meeting of the Council on Tuesday, February 1st, present, Messrs. C. S. Cantrell (in the chair) T. Beddall, J. Collins, H. Corbet, A. Garrett, A. H. Johnson, J. Naish, and J. Scott, it was resolved, that, at the forthcoming election, 40 names should be added to the present list of pensioners, viz., 10 male, 20 female, and 10 married candidates, thus raising the total number of pensioners to 170, not including the orphan children boarded and educated by the Society. The annual dinner was fixed for Wednesday, the 8th of June.

THE SEWAGE OF TOWNS.

At the January meeting of the Hexham Farmer's Club, Mr. R. WALLIS, the Chairman, read a paper on this subject, in which he said: I have nothing of my own, or, indeed nothing new, to bring before you on this important subject; but, by drawing your attention to the matter I may induce some one better qualified than I am to investigate the subject. It is a subject which must before long be not only investigated, but action must be taken to remedy the existing evils of the present mode of sewage of towns. It is a subject which is exciting great interest in this town at the present time; but I may be allowed to say it is not on that account I have chosen to bring the matter before this club, though I must say there is no town which I am acquainted with that presents more advantages for efficient and profitable sewage operations. As the subject is *sub judice*, I will not allude to it any further. The chief reason for me presuming to bring the subject before you is the fact that agriculturists are really the persons most interested. To quote from the celebrated Mr. Mechi, who has done good service in this cause, both by his pen and by practical application—he says: "If the money value of the contents of the sewers could be shown to the British farmer in bright and glittering heaps of sovereigns, he would grasp at the enormous wealth, and make great efforts to attain it. Our sewage, although a less perceptible treasure, is not the less a real one. I am bound in truth to say that I have not seen any practical desire or effort on the part of the British agriculturist to obtain this treasure. If it is worth having it is worth asking for; but it has not been asked for; and the apathy and miscalculation on the subject must amaze every unprejudiced man of calculation. Is human excrement less valuable than that of animals?" The subject is, at the present time, receiving that attention it is entitled to from the various scientific bodies. A committee, appointed by the British Association, is now collecting evidence on this subject; it has been discussed at a meeting of the Social Science Association, and several articles have appeared in the leading scientific journals; and the Government have been induced to pass a Bill "For Facilitating the More Useful Application of Sewage;" but I am not aware the agricultural community have shown themselves to be at all alive in the matter. Whether we regard the question of the sewage of towns in relation to the health and comfort of the people, or the utilization of the sewage matters in relation to agriculture, it assumes an immense national importance. It is the difficulty of reconciling these two points which invest the subject with so much interest. Hygiene is undoubtedly the first consideration, but it has hitherto engrossed almost the entire attention of the different authorities constituted to carry out the question. Had the modes employed been successful for the purpose they were intended for, there might have been some excuse for the reckless and immense waste of the manurial products. But such is not the case. No one denies the desirability of cleansing our towns from the excreta of men and animals which are so prejudicial to health and comfort; nor does any one deny the value of the town sewage applied to agriculture; but no one is satisfied that either one or the other of these desiderata has been accomplished. Enormous sums of money have been spent in almost every town in England on sewage operations, and in very few instances indeed have they proved successful. In very few towns, even where favourably situated, has the utilisation of the sewage been taken into consideration. The object has always been to find an outlet for the sewage matter, at the least possible expense, into the nearest stream or navigable river. This has turned out to be a great mistake. The concentrated accumulation of sewage filth along the banks of the streams has been the cause of febrile diseases and premature death; it has poisoned and driven away the fishes; and in some instances the mud has given rise to serious obstruction to navigation. London is a notable example of this, and every town where the sewage is poured into the streams is the same in a minor degree. A few years ago, when the sewers of London opened into the upper part of the river Thames, the deposit of sewage

mud on the banks was perfectly intolerable; the exhalations were most noxious and deadly, and the whole system demanded an immediate remedy. Under the engineering skill of Mr. Bazalgette, an elaborate system of intercepting sewers was devised and carried out, to convey the sewage to a point several miles down the river, beyond the densely populated portion of London (to Barking and Crossness), at the cost of £4,250,000. And what has been the result? The result of a survey last year shows that, near the northern outfall, a space of more than 40 acres, and near the southern outfall, of about 120 acres of the bed of the river has been covered by a deposit varying in depth down to 7 feet. Mr. Letheby reports that "The deposit consists of sewage matter. It is evident from what I know of the usual composition of mud of rivers, that this is a very large proportion of organic matter; and that, by undergoing putrefactive decomposition, the mud may be a cause of considerable alarm, especially as it there meets with sea water, the sulphates of which may, by the chemical decomposition of the putrifying mud, occasion the escape of much sulphuretted hydrogen, and set up that remarkably offensive change, which is the characteristic of the action of sea water upon sewage." This is the result of his great scheme, and in proportion of every town in England where the sewage has the outfall into the river. This great scheme was carried out purely as a matter of hygiene, regardless of the valuable manurial elements; though it must be borne in mind that the removal of the sewage from the Thames altogether was contemplated. The Metropolitan Sewage and Essex Reclamation Company intended to carry the great outfalls of the sewers further down to the Maplin Sands, which were to be irrigated by the sewage, and turned into a vast plain of market gardens. But the Board of Works wished to drive too hard a bargain, and the company was nipped in the bud. The Sewage and Reclamation Company stuck fast at their experimental farm at Barking, of which I will speak hereafter. The irrigation of the Maplin Sands must either be carried out by the Board of Works, or by some company who ought to be guaranteed 3 or 4 per cent. It would be a great experiment, and, if successful, would be limited in different parts of the country. But if this be successful, there still remain in the sewers the pestiferous gases. Several modes have been tried to get rid of these gases:—1st, by the use of ventilating charcoal grates; 2nd, by ventilating through chimney shafts; 3rd, by ventilating through pipes to the tops of buildings; and 4th, by diluting the sewage with water. None of these modes have been satisfactory, and Mr. Bazalgette states, in a report on this subject, that it would cost for plant £460,000, and £301,480 annually, thoroughly to ventilate the London sewers. These sewer gases, being compounds of sulphuretted and carbonated hydrogen, are lighter than common air, therefore have a tendency to escape, and hardly any gully or water closet, however well trapped, is free from them; but when a strong wind blows into the outlets of the sewers, the back rush of the deadly gases is intolerable. The water closet system, however well they may be trapped, is open to great objection, and in small and tenemented houses, where the people neither will nor can understand the mechanism, they are an intolerable nuisance. The whole system of sewage is wretchedly bad, and recklessly extravagant. It carries the liquid and solid excreta down to our neighbours to rot at their doors, and it leaves us a legacy of deadly gases to remind us that our endeavours to cheat nature has signally failed. To remedy the defects of the present system, a return has been made in many towns, particularly in Manchester, to improved privies and ashpits, catch pits, hermetically sealed boxes, and earth closets. Earth closets may do very well for small agricultural towns and villages, but I fear they are impracticable for large towns. The earth requires to be kept very dry; and three and a half times more than the quantity of the excreta is required. Burnt clay and charcoal are the best deodorizers for the purpose. They absorb the moisture and gases of the excreta, and prevent any obnoxious smell; when earth closets

are well kept they are very effectual. For a town of 100,000 inhabitants, 3,500,000 cubic feet of dry earth would be required to be brought in, and 4,500,000 cubic feet would have to be carted out again, an amount of carriage which would be almost impossible without interfering very seriously with the regular traffic of the town. But the greatest novelty of invention for remedying the defects of the present system of sewage is that by pneumatic force. In a "Work on the Sewage Question by F. C. Krepp," the whole subject of sewage by different countries is most ably treated; and Mr. Krepp, in that work, gives a most detailed account of a system by Captain Liernur, "for the daily inoffensive removal of fecal solids, fluids and gases by pneumatic force, combined with an improved method of sewage utilization." The work was very ably reviewed in the *Newcastle Daily Journal* of the 22nd July. The plan seems to be a most feasible one. It seems perfect in theory, if it can only be carried into practice. If it can, wealth and honour will be the sure reward of the fortunate discoverer. This system of Captain Liernur's realises the motto, "Rainfall to the River, and Sewage to the Soil." No system of sewage is worthy of consideration which does not give back to the soil that which in our food we have taken from it; and I consider the mere ridding ourselves of a valuable fertiliser, simply on account of the difficulty of dealing with it, quite beneath the enlightened spirit of the age. The subject is of such great national importance that we should not rest until some plan is devised to render sewage matter innocuous to public health and profitable to agriculture. It has been decided by those who have given their attention to the subject. 1st. That town sewage cannot be profitably utilised by deposition, filtration, or precipitation, and that none of the methods hitherto adopted under this system have effectually accomplished the dis-pollution of the streams into which the effluent waters are discharged. 2nd. That town sewage when applied in irrigating land, by natural gravitation, has invariably realised profitable results; and that the waters discharged from such land, after irrigation, are so far deprived of their noxious constituents as to be rendered practically innocuous. 3rd. That when judiciously applied, liquid sewage does not give off offensive emanations, but is immediately deodorised. 4th. That the soils best fitted for sewage operations are sand and light loam, and well drained clay. 5th. That the crops most benefited by sewage irrigation are Italian and other grasses and root crops. 6th. That the fertilising properties of sewage matters depend entirely upon the liquid portion, the precipitation being almost useless. In liquid and solid excrements, before entering the sewer, the fertilising properties are $\frac{7}{8}$ fluid to the $\frac{1}{8}$ of the solid. Now to get some idea of the value of the sewage, we will take our town population at 25,000,000, and we will assume that the excrements passed by every individual is equal in value to 10s., which is a moderate calculation (it has been differently stated from 8s. 4d. to 14s.), this will give us the enormous sum of £12,500,000 per annum. There is no doubt about the facts. This is a fair approximation of the sum we are wasting every year, in polluting our streams, and destroying our health, simply for not having the means of profitably applying it. But Boards of Health and Corporations must learn to know that the successful application of sewage matter to the land does not necessarily mean an immediate profitable mercantile speculation, but as adding to the wealth of the nation in the increased value of the land, and enlarging its capability of producing food for the people. We hear of many failures in the application of sewage to the land, but these may safely be attributed to improper application. One positive fact is worth a hundred negatives; indeed, sewage cannot be otherwise than beneficial to the land if properly applied; it contains all the salts and minerals which have been taken from the soil, and must be returned to it again for successive crops. The irrigation of the Craigentney Meadows is the oldest and best known example of sewage irrigation. What was once a barren sand, is now worth a rental of £30 an acre, from which five and six crops of grass are cut every season. The Lodge Farm at Barking is another notable example. I have not been able to get the recent information I expected about this farm. But there, on a stiff clay, they get five crops of Italian rye grass every season; their root crops are something so enormous that I dare not venture to mention the weight without having my memory refreshed; strawberries and cabbages also produced very heavy crops at the Lodge Farm. In a paper read by the Earl of Essex, some

years ago, at the meeting of the British Association, he says, "There seems to be no limit to the quantity of sewage for grass land, provided the soil be porous and well drained. I cut my grass five times in a season, and my root crops are the largest I ever saw. One year I lost almost all my wurzel by the fly and drought. I transplanted five acres of wurzel, and turned the sewage upon it, that yielded 45 tons per acre; and kept 34 bullocks all the summer, with as much as they could eat, from seven acres. The liquid sewage sinks into the soil at once, and often becomes imperceptible in about half an hour, always within a day." About the year 1700, with a population approaching to 7,000,000, we annually exported 100,000 quarters of corn. Now, we import from 30 millions to 40 millions annually, and our population approaches 30 millions. We also import fertilizers to the amount of two millions sterling, which is equivalent to a tax upon corn. But we must recollect that the supply of these fertilizers is not inexhaustible. The supply of bones from Denmark, Russia, and South America, and of fossil excrements, and guano from Peru will cease, and then what will be the condition of the fields of England if we continue in our reckless course? In an old country, like this, you cannot have food without manure; therefore, with an increasing population, and a diminution of home grown products, you sap the very foundation of your country's greatness, and bring her to the verge of misery and destitution.

Mr. CATCHESIDE said that besides this question of sewage affecting their town it was one which ought to demand their attention both in a commercial and in a scientific point of view. As was observed by their chairman, the first question that they should have effectually settled respecting the sewage of towns was the fulfilment of hygiene strictly as a scientific principle. The proper drainage of towns and the thorough removal of sewage and all noxious gases of every kind should be first attended to. The great difficulties appeared to be, firstly, in the great waste of water necessary to flush the sewers, in order to carry away the sewage into the river; and, secondly, the pollution of the streams provided by nature for their good. He referred to the sediment left by sewage in the river at London, which was seven feet in depth, and if he might draw a comparison between our town and London he might venture to say that they would have no such depth in the river Tyne, because there was nothing near the same quantity of sewage going into the river. For those who advocated the dry earth system—the mixing of excrement with soil—this comparison might prove an important fact. In London they found the water system fail, with all the immense quantity of water with which the sewers were daily flushed to carry the sewage into the Thames. Taking this into consideration, and the mere nothing in the way of waste of water at Hexham, how could they apply to London the dry earth system, on account of the immense quantity of dry earth and ashes that would be required to be mixed with the sewage of London, when they found water the most plentiful in that way fail to effect the object, for it carried the sewage into the river and left it there, and did not thoroughly carry it away? Even supposing it were possible to adopt the dry earth closets, and farmers would buy it, where could they store up such an immense quantity of sewage which left seven feet thickness in the bed of the river? The dry earth system would prove itself impracticable in another sense—they would find that hygiene was not strictly carried out. Mr. Catcheside gave, as an illustration, Bellingham, which, he said, was in an abominable state, the air being impregnated with various noxious gases emanating from ash-pits, &c., the dry earth closets being in use at that place. It would never do to sacrifice the health of the townspeople to satisfy the wants of farmers in providing manure for them to buy. In Hexham he knew, for a positive fact, that all the sewage could not be sold if utilised; farmers did not want manure all the year round. Sewage naturally would have to be prepared all the year round, and he wanted to know where they would store it? Some of it must go to waste; it could not be used at certain times of the year; they had not land to put the sewage upon by irrigation. Certain individuals had refused to have it put upon their land, as it would come in the way of their agricultural programme. With respect to putting sewage upon land by irrigation near a town, or where people dwell, they would find that various gases emanated from those fields which were irrigated with it, and in certain winds they would get the benefit of those gases in quite as great a degree, if not greater, than when blown up the sewers. Water-closets

were acknowledged to be a great nuisance, but they must put up with them if they could not get a better system. The question was whether the water-closet was not more healthy than the dry-closet system? The latter might be applicable to small villages, where there was a sufficient demand to buy up the manure thus formed. As to the chemical constituents of sewage, by precipitation the liquid portion, by far the most valuable, was allowed to run to waste. In conclusion, he said this question had not seemingly acquired that importance which it deserved and ought to receive at the hands of scientific men, though no doubt some day they would get a solution of this very important problem. It was not only a problem which concerned the sanitary condition of towns, but was one which involved deliberate waste on the part of a great and enlightened nation.

Mr. SMITH said they would be well aware that there was considerable discussion going on in this town respecting the sewage question. He might say that the Hexham Local Board were carefully considering it, and no Board could be more anxious to carry out all the improvements they possibly could than they were. He was one of the members of the Board, and he was in favour of irrigating land with sewage by means of gravitation, and if they could get land at a reasonable rate in the neighbourhood they would find the sewage to be very profitable. The population of the town might be taken at 5,000, and if an income of £2,500 a-year could be derived from it, it would more than pay all their rates. Mr. Smith had no doubt but that the time would come when the utilization of the sewage of towns would become exceedingly valuable, and instanced the case of Edinburgh, where pure sand when irrigated with sewage yielded large crops. At Aldershot the application of sewage to poor clay land had

also been attended with the most successful results, and he had personally seen its astonishing effects in the neighbourhood of London. Mr. Smith concluded by proposing a vote of thanks to the chairman for his excellent paper.

Mr. H. STEPHENSON seconded the vote of thanks, and said he had no doubt when they had the paper printed, and time to think over it, they would see the utility of it. It was the business of the farmer to get his manures as easy as possible, and to produce the greatest crops.

The CHAIRMAN, in response, said he was glad to hear that Mr. Catchside coincided with his views that the earth-closet system would not do for large towns, and seemed to doubt even whether it would do for small villages. He wished to know what system was adopted at Bellingham, to which Mr. Catchside had referred. Was it merely the common privy?

Mr. CATCHSIDE: Just the common ash-pit privy.

The CHAIRMAN said there was an improved one, and it was that to which he had referred in his paper. The simple ash-pit privy was abominable. Mr. Catchside asked what they would do with sewage, as they could not irrigate land with it all the year round. He replied that undoubtedly they could; and he found that at one place where it had answered the purpose best, that from 50,000 to 60,000 gallons per acre were put upon the land every time a crop was taken off. No smell arose from it, and he supposed Mr. Catchside spoke from book and not from fact. The earth was the only effectual deodoriser, and they were distinctly told that within half-an-hour the smell disappeared, and always within a day. He felt much gratified to have a vote of thanks proposed to him, and he returned them his cordial thanks for the honour they had done him.

MR. HALL MAXWELL.

No one was more jealous of his own or his Society's dignity, and his eye would flash and the colour would mount to his cheek at a word. He delighted most in marshalling statistics and annexing districts at his desk, but still he was supremely happy in the show-yard. Everything was done there with great dignity and order, and the Scottish bench would sometimes chaff their coadjutors from England overnight, and tell them that Hall Maxwell never admitted a judge into the show-yard unless he presented himself in full court-dress. On the opening morning he might be found in the pay-box for a few minutes, helping to gather the crowns, and exchanging a word or a nod with each member as he came in; but he soon retired, and for the rest of the week the saddle was his throne. He would be galloping here, there, and everywhere, as field-marshal, on his bay cob, setting lords, baronets, and lairds to work as "attending members" to the different sets of judges; and he was a plainish speaker, sometimes, if things did not go just to his mind. In short, both there and at Albyn Place, he was quite the autocrat of the Society; but, although they somewhat felt the bondage, they were very proud of him, and quite content to set off the marvels he had wrought for them against what many thought, and some termed "dictation." If any of the latter were unduly captious, he caught them without more ado and made directors of them, and they soon ceased from troubling. This mode of bland absorption was very transparent, but was never known to fail. Public business often took him to London, and no one could take charge of a Parliamentary bill better. If he appeared in a Committee-room to support or oppose on behalf of the Society, it was with such a well-marshalled and serried mass of facts and witnesses that it was always odds on him. At Battersea and Paris he was quite in his element, looking after Scottish interests. When in '61 he led the hundred-and-twenty herdsmen and shepherds to Battersea-fields, he lodged them in Edginton tents, and furnished them with beds borrowed expressly from the Tower. They had regular night-watches like soldiers; certain detachments of them made holiday at the Exhibition or the Crystal Palace, and on Sunday they were marched to Westminster Abbey. This was the only time that we ever saw him in complete sympathy with the stock classes. He seemed to care nothing about the very finest show of animals or their points, and to merely regard them as necessary links in his system. Neither

Belville, nor old Charlotte, nor Colly Hill, nor London Tam, "that very Blair Athole among Clydesdales," had made any impression on him. He only wished to see the classes worthily filled; the cracks he left to his friend, Mr. Gourlay Steel, "to be translated." As a private companion none could exceed him, and to us his stories were all the more salient, when they turned on his recollections of his own Society. He loved to recount the Parisian speculations and observations of "Boghall, who did him such yeoman service as cattle manager on that famous international trip; and he unconsciously gave us a delightful specimen of his best official manner in his recital of "Duncan's Arrest at Perth." It seems that the late Duke of Athole, who was then president of the Society, went to Mr. Duncan the night before the show opened at Perth and demanded a stock catalogue. With answering fidelity to his chief, who had given express orders to the contrary, Mr. Duncan expressly declined to hand over, and the Duke (whose Highland blood was very easily roused) ordered him forthwith into a cab, and taking his seat beside him, drove straight off to Mr. Maxwell's inn. The latter was summoned from dinner, and on going into the lobby, heard the indictment which the Duke delivered with immense emphasis, holding the accused by the collar. Then Mr. Maxwell struck in, appealing to the Duke as one who had been in the army, and knew the value of rigid discipline, and showing his Grace that "my orders are only your orders—even a president cannot break his own rules;" and so the upshot of it was that the Duke doffed his bonnet, and made a most gracious bow—"Mr. Duncan, I humbly beg your pardon." Such was Hall Maxwell; and Scotland did not let one who had served her so well and so long retire without a substantial reward. On January 17, 1886, he was presented with 1,000 gu. and a handsome service of plate, and was also requested by the directors of the Society to sit to Mr. Gourlay Steel, for his portrait. They little thought how soon that portrait (which is hung, among the few that have attained such honour, in their council chamber) would be all they could look upon. He was still in the very prime of his mental vigour; and, if health had been granted to him, he might have reasonably looked forward to another twenty years of usefulness in his country.—From The Druid's new work, *Saddles and Stirrups*. [Can any of our readers favour us with a copy of "Investigator's" pamphlet, the point of which was an attack on Mr. Maxwell?]

THE WELSH MODEL AGREEMENT.

TO THE EDITOR OF THE MARK-LANE EXPRESS.

SIR,—In your impression of the 17th Jan. you publish a form of agreement or lease adopted by Lord Lisburne, drawn, as his agent states, for the *protection* of the “improving tenant”! It is a very lengthy and peculiar document. On reading it I thought of the nursery rhyme, “Taffy was a Welshman, Taffy was a ***” if all this be needed to keep a Welsh tenant honest and improving! I read it twice, but, I fear, missed the improving part. The third time pays for all, I said, and I read it the third time; but my bacolic mind became somewhat obfuscated with the interminable lessee, lessor, executors, administrators, assigns, &c., &c.; and if the Welsh “bacolic mind” be anything like the English, I fancy it will not be improved in this fashion. There are some things no fellow can understand as improving any one but the landlord. Fancy a landlord reserving the right to make plantations anywhere on a farm, “the tenant not being allowed to destroy game, wild-fowl, or rabbits, *but to use his utmost endeavour to preserve them*; tenant at own cost to paint with two good coats of oil paint, every three years, all wood and iron work;” tenant at his own cost to insure and keep insured all buildings, &c.; to crop according to rule; not to sell off any roots, hay, straw, &c.; to repair all gates, fences, roads, bridges, &c.! Not a word about materials, found; not a word about allowance for cake or corn consumed, nor for artificial manures used. If the tenant absent himself for two months, though it may be for the *improvement* of his health, he is to be improved off the farm! Lastly, he is to pay all the costs and expenses of these presents (and a pretty present too), *and of the counter or duplicate*. Why not say at once, “Dance as I bid you, and pay the piper”? In order that our Welsh friends may have some idea of a liberal agreement I enclose a copy of Lord Harrowby’s, read by him at a meeting of the Staffordshire Chamber of Agriculture, which you will perhaps publish.

Yours truly,

Eford Park, Jan. 26.

GEO. A. MAY.

The buildings, gates, and premises shall be kept in repair by the said tenant (damage by fire or tempest excepted, for repairs consequent upon which all carting shall be done by the said tenant) being allowed for that purpose the necessary timber in the rough, bricks, stone, and tiles or slate; and if the said tenant shall neglect to do any such repairs for the space of twenty days after having received notice in writing from the said landlord or his agent of the need thereof, the said landlord shall be at liberty to cause such repairs to be done, and may recover the tenant’s share of the cost thereof from the said tenant as and for rent in arrear. The woodwork of the inside of the house shall be painted once in every ten years, and the outside of the house and such parts of the buildings as have usually before been painted once in every five years with two coats of good oil paint; the other outside woodwork of the farm buildings not painted shall be gas-tarred once in every ten years, the cost of such painting and gas-tarring to be borne equally by the said landlord and tenant. Any draining required, and sanctioned by the landlord, will be done by the said landlord, the said tenant carting the pipes necessary for that purpose, and paying an additional rent of 5 per cent. per annum on the cost thereof. All hedges, fences, watercourses, ditches, and drains shall be kept in good order, and all thistles, docks, and other noxious weeds on the lands, hedgerows, and adjoining roads cut so as to prevent their seeding by the said tenant, or may be done by the said landlord, and the cost recovered as above stipulated for repairs. All rates, parliamentary, parochial, or otherwise, chargeable upon the said farm

shall be paid by the said tenant, tithes, land tax, landlord’s property tax, and insurance upon buildings excepted. All hay, straw, potatoes, roots, cabbages, and other food for cattle grown upon the said farm shall be consumed thereon, or if sold, one-half of the proceeds of such sales shall, within six months after any such sales, be expended in manure approved by the landlord or his agent, to be applied either to green crops or to the pasture land, the other half in oilcake or linseed to be given to cattle or sheep; all manures, whether made from the produce of the farm or purchased in exchange for such produce sold, shall be used upon the said farm, or in the last year of the tenancy left for the benefit of the succeeding tenant. Notice shall be given by the said tenant to the said landlord or his agent previous to any such sale of hay, straw, or other produce, and vouchers shall be produced for the manure or oilcake brought instead thereof. If any hay or straw be destroyed or damaged by fire, the value thereof shall be expended in the purchase of other hay and straw, or in manures and oilcake in the same manner as if such hay and straw had been sold. The meadow and pasture land shall be manured after every alternate mowing, with not less than ten loads per acre of rotten dung, or fifteen of long manure or good compost, or an equivalent in ground bones or other manure approved by the said landlord or his agent. The arable land shall be kept during the tenancy under this agreement in a clean and good state and condition, and so cropped that at the expiration thereof the arable land shall be in the following condition, or the said tenant shall pay to or be paid by the said landlord for any deviation therefrom such sum as the arbitrators appointed as hereinafter mentioned shall determine. One-half of the arable land shall, on such expiration of tenancy, be clean and in good condition and fit to plant with white fallow crops; of such half part, one moiety shall have been sown (with green crops) during the previous summer, the other moiety thereof shall have been wholly under clover or mixed grass seeds, or part in clover and the rest beans or peas after being manured, none of the clover or other grasses having been allowed to stand for seed. One-fourth of the arable land shall have been sown in the spring of the year preceding the termination of the tenancy with clover or other proper mixed grass seeds upon land fallowed the previous year and clean, the seeds, sowing, and harrowing to be paid for by the said landlord or his in-coming tenant, provided they have not been grazed after harvest. Not more than one-fourth of the arable land shall require to be fallowed in the year after the termination of the tenancy, nor require an outlay of more than fifty shillings per acre to clean it; if it require less than that sum the said landlord or his in-coming tenant shall pay the difference, if more than that sum the said tenant shall pay it. And it is hereby agreed that not later than one month before the termination of the tenancy under this agreement the said tenant and the said landlord or his in-coming tenant shall each appoint an arbitrator; these arbitrators shall meet not later than ten days before the expiration of the tenancy, and having appointed an umpire, shall proceed to consider the claims made by either party; in case either party refuse or neglect to appoint an arbitrator, the other may nominate an umpire, who shall have the same powers as if he had been appointed by the arbitrators jointly, and any award made in pursuance of this agreement shall be final and binding upon both parties, and may be made a rule of any superior court of law; the terms “clean and in good condition” and the construction of all covenants and stipulations herein used, shall be understood in a reasonable and practical sense, and the claims contingent thereupon treated accordingly. The arbitrators shall first consider how far the state of the farm differs, if at all, from that herein stipulated, and they shall decide whether the said tenant or the said landlord or his in-coming tenant is entitled to any and what compensation on account of such variation; they shall then settle the other claims between the parties upon the following basis: The said landlord or his in-coming tenant shall pay after the rate of fifty shillings per acre for all land in excess of one-half which, under the above conditions, is fit to be planted with white straw crops, or shall be paid by

the said tenant at the same rate for all short of one-half of the arable land so fit. Not less than one-fourth of the clover or mixed grass seeds shall be mown for hay during the last year for the use of, and to be paid for by, the in-coming tenant; for the remainder of the land whereon clover or other grasses have been grazed the whole summer by sheep the in-coming tenant shall pay after the rate of forty shillings per acre, provided such land be clean, and that only one crop of corn has been taken since the previous fallow. The said tenant shall be entitled to the sum of fifty shillings per acre for all clean fallows. If not clean and ready to plant with corn, the cost of making them so must be deducted. If the said tenant has not sold hay, straw, or roots, and has purchased manure within the last two years of the tenancy, or if he has purchased manures in excess of the quantity required to replace the hay and other produce so sold, he shall be paid one-half the cost of all such purchased manures in excess of the quantity so required which shall have been applied to green crops or grass land in the last year of the tenancy, and one-fourth of the cost of that in the last year but one, such cost not having exceeded forty shillings per acre. All unprepared bones and lime used upon any part of the farm during the last four years of the tenancy shall be paid for, deducting one-fourth for every year's use, and on pasture land during the last six years, deducting one-sixth for every year's use, provided such pasture land has not been mown in that time, and for every other fertiliser of a permanent nature, such allowance as the arbitrators may determine, and also one-half of the cost of all oilcake or linseed consumed during the last year, and one-fourth of that in the last year but one, provided such oilcake or linseed has been given to cattle and sheep, not horses. The said tenant shall not retain any part of the buildings or land after the termination of his tenancy (except the use of the barns for thrashing and winnowing only), but shall be paid the value of all growing green crops, and of all hay or straw remaining on the premises. The arbitrators shall fix the times for thrashing and delivering such straw to the in-coming tenant. The said tenant shall be paid such sum as the arbitrators may determine for all permanent improvements made with the sanction in writing of the said landlord or his agent. In case this tenancy shall determine by bankruptcy or assignment, or deed of arrangement, or composition with, or for the benefit of creditors, the arbitration clause shall apply, and the time for nomination of arbitrators shall be one month after such determination, and the arbitrators or arbitrator shall have full power to adjudicate on all questions of compensation, having regard to the time when the tenancy so determined, and the assignees or trustees shall stand in the place of the tenant.

THE WELSH LIBERAL AGREEMENT.

SIR,—I can picture to myself the astonishment and indignation of Lord Lisburne and his agent at the unexpected treatment which their liberal agreement has received at the hands of "plain practical" *Lincota*, and also in your editorial criticisms. Their ill-advised attempt to teach the landed proprietors and land agents of England in general, and of Wales in particular, how to construct a "liberal" yearly agreement, has exposed them to well-merited ridicule, and shows that they have yet to learn the rudiments of agricultural politics. For my part, I look upon it as an endeavour to foist upon the public as *original*, what looks very much like a patched, and slightly altered form of a Scotch lease, as I can lay my hands on one constructed more than half a century ago which bears a very striking resemblance to Lord Lisburne's "new lease."

I have always thought that yearly agreements, and even leases for a term of years, should be as simple and condensed as possible, but it would appear that Lord Lisburne and his agent think that in a multitude of words there is wisdom. The lengthy preamble, in the first instance, has a strong savour of the legal gentleman pervading it, than which nothing is more obnoxious to the feelings, or more pernicious to the welfare of the tenant-farmer. The different clauses of the lease are also over-burdened

with words, while they lack common sense and discrimination. The tillage clauses, for instance, imply that "the practice of good husbandry" forbids the disposal of hay, straw, and roots, otherwise than by consumption on the farm where they are grown. But this does not necessarily follow, as the most of the hay, straw, and roots are sold on some of the best farms which have come under my observation, and the fertility of the land is increasing instead of decreasing. This may be a puzzle to our would-be instructors, Lord Lisburne and his agent, but I will enlighten them as to the process should they be sceptical. It seems to me to be the very opposite of liberality that a tenant may not have the liberty to sell hay, straw, or roots, to the amount of £50 or £100, if he invest a similar sum in the purchase of artificial feeding-stuffs, or fertilizers.

But liberality to the tenant culminates in clause 8. I should like to know how the first part of that clause can be reconciled to the following reservation contained in the indenture. I will quote the sentence entire: "Except and reserved out of this demise, unto the said Earl and his assigns, all such parts of the said farm on which any timber or underwood is growing, with power at any time to plant trees, and to enclose or make plantations on any part of the said farm." And yet in clause 8 the tenant is bound to preserve "all trees hereafter to be planted, from all injury by cattle, or sheep, or otherwise." Would Lord Lisburne throw the burden of keeping up the plantation fences on the shoulders of the farmer? If not, what does clause 8 mean? The concluding part of clause 8, in a cool and summary manner, makes the tenant, in effect, the landlord's game-keeper. Notwithstanding all that has been said lately about the policy and justice of allowing farmers to destroy rabbits as vermin, Lord Lisburne takes a retrograde step, and deliberately orders his tenants by not merely asking them, but binding them to preserve rabbits, to destroy the fruits of their legitimate toil!

"Are all thy conquests, glories, triumphs, spoils
Shrunk to this little measure?"

One more point I am desirous of being enlightened on, and that is the difference between "the spending price" and the selling price of hay, straw, and roots. If Lord Lisburne's agent would kindly state a fixed rule for the purpose of determining this question, he would lay the public under an obligation to him.

Lord Lisburne's "new lease"—his agent's nostrum for the cure of bad farming in the Principality—turned out to public view, and inspected on every side, is a lamentable exhibition. I trust that it will be contemptuously rejected and condemned by the farmers of Wales. I am, your obedient servant,

Jan. 27.

A WELSH FARMER.

ANOTHER MODEL AGREEMENT.

SIR,—*Timeo Danaos et dona ferentes*, which being translated bucolically may be rendered, "I fear the landlord's agent even when offering an agreement professedly in the interest of the tenant."

Surely, sir, Mr. Gardener cannot expect anybody to accept his agreement as one which will secure to the tenant all that he is entitled to, or preserve him from the influence of the landlord. Many of your agricultural readers I have no doubt will remark to you upon various points connected with the farming clauses of this agreement; but I should like to call attention particularly to the fact that, although the tenant is nominally entitled to compensation, yet the protection is but small, considering that he can be turned out at the end of any year, at six month's notice, and that even if fully paid for all im-

provements, it will be a heavy loss, and great discouragement to him to remove—for, say, voting against his landlord's wish. This agreement appears to be drawn with view to preserve the landlord's territorial influence.

With respect to the schedule of allowances, and the clauses in the agreement relating thereto, I conceive that they are "a mockery, a delusion, and a snare," inasmuch as everything except the liming and seeds is so hampered by the agent's certificate, as, in case of offence given by the tenant, to put him at a tremendous disadvantage. It is very common with railway and other companies when entering into contracts for the making of lines, &c., to insert a clause that everything is to be certified by their engineer, and the effect of this is well-known: unless the contractor keeps well in with the engineer, he may be entirely refused his certificate—and he has practically no remedy. So it may be in this case. A tenant would be entirely at the mercy of the agent, who, of course, would only act as the landlord wished him.

I am, sir, yours obediently,

A TENANT-FARMER AND AN ATTORNEY.

Manchester, Jan. 22.

ANOTHER AGREEMENT.

DEAR SIR,—Circumstances have arisen that make it necessary there should be a fresh agreement between the owner of my farm and myself; and though the farm in question is very near Wales, we think the "Welsh Agreement" hardly suited to our case. We have, therefore, drawn up the following agreement, but before we sign it I shall be glad to have the opinion of your correspondents upon it.

As I am liable to be turned out at two years' notice, it has not been thought necessary to put in stringent clauses as to the mode of farming; as, of course, the owner can get rid of me if I farm badly, and is protected after I have notice to quit.

Yours faithfully,

BORDERER.

By this agreement, made on the — of —, A.D. 1870, between A. B., of —, and C. D., of —, A. B. agrees to let, and C. D. agrees to take, the farm called —, now in his occupation, with the house, buildings, garden, and cottages thereon, and the shooting of the woods, for two years, from the 25th of March next, and thence until two years' notice to quit at Lady Day shall have been given by A. B. to C. D., or six months' notice shall have been given by C. D. to A. B., at the annual rent of £—, payable quarterly, and a further sum of £10 for every acre of old pasture converted into tillage by C. D., and at the same rate for smaller quantities. And it is further agreed that after notice to quit, as above mentioned, shall have been given by either party, all the hay, straw, and green crops, and all the roots grown on the farm, except three acres of potatoes in a year, shall be consumed thereon; and not more than half the tillage sown with white corn crop in a year, and that no timber or fruit trees shall be cut down or injured by C. D., and that on quitting he shall have all the outgoing crop of wheat, not exceeding one-fourth of the tillage, and may take away all buildings hereafter erected by him, and iron fencing erected by him. A. B. undertakes to keep in repair the house and buildings; and C. D. undertakes to keep in repair all gates, stiles, and fences, on being found timber in the rough.

A. B. undertakes to pay C. D. when he leaves the farm for all purchased manures used for green crops during the last year of his tenancy, and half the cost of all oilcake consumed on the farm, and the cost of all clover and grass seeds sown the last year.

THE "WELSH AGREEMENT."

SIR.—Now that so much has been said about the "Welsh Agreement," I have to crave your permission to say a few words in reply to some of the criticisms thereon, which have lately appeared in your columns. There is always a sufficiency of the currency called "abuse" in circulation, and to any amount of such I offer no objection, but I will take the liberty of drawing your attention to one or two of your observations, which savour of "unfairness," and are altogether aside from your usual impartiality; in referring to the agreement, you say it is "a document in writing, of which the agent of the property proudly (?) says, 'I shall be very glad if I have suggested anything that may lead to a more liberal construction of agreements in general.'" Whereas in my letter to the editor of *The Welshman*, from which you quote, I say, "I shall be very glad, if in venturing on these few observations on a very important subject, I have suggested anything that may lead, &c.," evidently referring to the observations in my letter, and not the Agreement, as the sentence in the mutilated form you give it would imply. Again, you say, "He is evidently proud of his handiwork, and openly offers it as an example to the Principality and the criticism of others further a-field." The remarks of the editor of *The Welshman* will satisfactorily dispose of that imputation, and, along with my letter to him, show that what alone induced the consent to publish the agreement was the wish to have discussed various clauses which had been introduced into it, containing a guarantee on the part of the landlord to repay to the tenant, at the termination of his tenancy, the amount of his outlay (or a proportion of it) on improvements of a permanent nature; such clauses being quite unusual in yearly agreements in the Principality, and they will, notwithstanding all that has been said against the agreement, be found important to the tenants for whom they are intended. A "Welsh Farmer" seems to have been mightily afraid that an attempt was being made to "teach landlords and land agents." It may perhaps tend to soothe his ruffled dignity when I assure him such an idea was never entertained. I am none the less glad, however, to find their honour as zealously guarded by a "Farmer," although I admit he makes a "muddle of the thing" when a little farther on he talks of "our would-be instructors."

After all, I doubt, it will generally be found that agreements must be constructed to meet the state of matters in the different districts to which they apply. You can hardly ignore what actually exists, and deal altogether speculatively, with an "advanced state of things," which, however desirable, has yet no foundation in fact. An agreement, for instance, may be well adapted to the advanced state of agriculture in Lincoln, Stafford, and other counties, but at the same time totally inapplicable to the greater part of Cardiganshire; and it is perfectly easy, perhaps quite natural, for gentlemen living in these favoured localities to sit down and stigmatise as needlessly stringent the clauses of an agreement which deals with an entirely different state of things from those with which they are surrounded, and of the actual nature of which, it would appear from their remarks, they have but a faint conception—equally easy is it to denounce as "antiquated" and "uncalled for at the present time" clauses which have to deal, somewhat minutely it might be, with evils which cannot be reached in any other way. It is admitted that the "beginner should try to cultivate his land on some established principle of good husbandry," and it must be equally desirable that those at a later stage should do so. What, then, has the agreement in question to deal with? With an advanced state of agriculture? With scientific farmers? men of capital and skill, cultivating their lands in the best manner? who manure and clean them thoroughly, and sow them down in good condition, with clean seeds? cut their weeds, and keep their fences and premises in fair order? with men, in fact, who have learned to manage their farms "according to some recognized principle of good husbandry," and who expend large sums annually in the purchase of supplemental manures and feeding stuffs? In the majority of cases, most distinctly so. Doubtless we have some worthy exceptions, where the best management prevails; but, strange as it may appear, the neighbour on the other side of the hedge to such will be found twenty years behind; and all in a great measure owing to that absurd jealousy of what is considered an "at-

tempt to teach" (fairly exemplified in a "Welsh Farmer's" letter), which makes them stick like barnacles to their old customs.

Stripped of all fictitious covering, what are the actual facts with which we are confronted and forced to deal? Tenants with, in too many cases, an insufficiency of capital, and a disposition to remain *in statu quo*; over-cropping a prevailing sin; green crops and fallows generally "half-manured" and worse cleaned, followed by two and not unfrequently three white straw crops, with the last of which is sown, not well cleaned seeds, but more generally stuff collected from the barns and hay lofts, and the condition of the land thus laid to grass may be imagined, though that and the consequent evils to the tenant cannot be so easily described; add to all this a neglect to cut weeds, repair fences or gates, or clean ditches, and you have a picture not very flattering, certainly, or indicative of the "advanced state of the times"—but none the less true. How then can such evils be dealt with, unless they are adverted to in the agreement? and if the clauses should be thought too minute by those unacquainted with the circumstances which render them necessary, they cannot, unless proved to be at variance with the requirements of good cultivation, act as a hindrance to the efforts of a good tenant, while they may be a check on the reprehensible habits of a bad one. Now, many of the evils of the system I have mentioned, prevail on estates where there have been very few changes with occupation of the land during the last twenty or thirty years, to unsettle the minds of tenants, and "nip in the bud" any desire they might have to improve and keep pace with the "times." On the contrary, any tenant who kept within the limits of decency, and paid his rent, might feel comparatively safe from being disturbed. Some may say the time has gone by when men who will not manage their farms properly can be allowed to hold them; let the land to men of intelligence, skill, and capital; give them sufficient security, and hamper them by no unnecessary restrictions as to cropping, &c. Well, when such is done, by all means let it be so; but, on the other hand, few will question the humanity, if not the policy, of giving the present occupiers a chance of gradually making up lost ground, even though it should necessitate the retention in the agreement of a few clauses which might otherwise be considered "antiquated."

As to the clause providing for the consumption on the premises of all hay, straw, and roots grown on the farm, if it is seen that a tenant is managing his farm liberally, the permission to sell is never withheld, should a fair return in some shape be made to the farm; but it is quite imperative to have this clause to prevent an "unprincipled" tenant who contemplates leaving, or gets "notice" from impoverishing the farm; and this remark applies equally to the clause limiting the extent of grass lands to be cut or mown, when, as is sometimes the case, an outgoing tenant will sell off as much of his stock as he can, and cut the grass lands with a view to mulct the incoming tenant.

You seem to object to a tenant being required to have the sanction of his landlord before executing any drainage, fencing, or other works of permanent improvement, the cost, whereof,

or a proportion, the landlord becomes liable to repay the tenant in the event of quitting. This, I think, no reasonable tenant will object to. It cannot be expected that a landlord will put himself without restriction into the hands of his tenant, who may, by a very injudicious expenditure on works of that description (which may or may not be actually requisite), involve him to a very serious extent. If a landlord is to be liable to pay, he ought certainly to be a consenting party to the expense. A landlord requires the tenant's consent before draining a field for him, and charging him 5 per cent. on the outlay. Why should the rule not work both ways? As to limiting and the general management of the farm, there is no provision for the landlord's consent being first required, or, indeed, required at all. Mr. May cannot see why a landlord reserves the right to "plant any part of the farm." When I say that this refers generally to high exposed land where planting would in all cases be a "blessing," and when the poorest and most exposed parts are selected and compensation given, the clause will not appear very formidable; while "planting" is in all cases first done by the proprietor; the cost of the agreement is restricted to the price of the stamp, in most cases only a few shillings. To another of Mr. May's objections of "cropping according to rule," I will merely say that if the course of cropping to which his agreement has reference was suited to the locality, there could be no earthly objection on the landlord's part to adopt his tillage clause; but if the tenant under a yearly agreement with such a clause did not adhere pretty closely to "rule," he must make up his mind to "pay the piper" rather sharply in quitting. Allowances for artificial manures, feeding stuffs, &c., when rendered necessary by the tenant's management, can be introduced into an agreement without any stretch of liberality on the landlord's part.

One word to a "Welsh Farmer." He is puzzled with Clause 8, yet it is very simple: "the landlord puts up and keeps in repair all plantation fences;" yet the tenant is bound to protect trees, &c., from all damage, with his cognizance, either by the trespass of stock, or the cutting or destroying by servants or others. The "spending" price of any article of fodder is just the "consuming" price, or the value which a farmer considers a quantity of hay, straw, or roots to be to him when used on his farm, and which can be easily arrived at by any practical arbitrator.

Although game, including rabbits, are "reserved," it is not by any means intended that tenants should suffer by their depredations; and, where found advisable or necessary, permission to destroy will be given by special agreement. The permission to farmers to kill rabbits on their farms will do them little good, unless they are well kept down in the covert.

Apologising for the length of my remarks, I have the honour to be, sir, your obedient servant,

Wenall House, Feb. 10.

ROBT. GARDINER.

[We certainly understood that Mr. Gardiner's letter to *The Welshman* was intended as a kind of running commentary on the agreement, as published in the same number; but we are glad now to gather that it is not intended to very minutely observe or enforce some of the very curious clauses of that very curious document.—Ed. M.L.E.]

THE CENTRAL CHAMBER OF AGRICULTURE.

A meeting of the council of the Central Chamber of Agriculture was held on Tuesday, Feb. 8, at the Salisbury Hotel, Colonel Tomline, M.P., in the chair.

A recommendation from the auditors that a Finance Committee should be appointed was acted on, and Mr. Smythies, Mr. Willson, and Mr. Neild were chosen to form such committee.

The twenty-six members of the council were appointed the Business Committee, with power to add to their number.

Sir MASSEY LOPES, as chairman of the Local Taxation Committee, presented its report. It said—

The Local Taxation Committee report that at their last meeting, held December 7th, they appointed Sir Massey Lopes, Bart., M.P., Mr. Albert Pell, M.P., Mr. Arthur Startin, and Mr. B. H. Masfen, adjudicators of the prize of £50 for the best essay "On the Injustice, Inequalities,

and Anomalies of the present Poor Rate Assessment, and of the Incidence of other Local Burdens of England and Wales." The essays, sixteen in number, having been placed in their hands, these gentlemen unanimously awarded the prize to the essay bearing the following motto: "This is not the cause of faction, or of party, or of any individual, but the common interest of every man in Britain" (Junius), which proved to have been written by Mr. C. F. Gardner, B.A., of 10, St. Michael's Terrace, Stoke Damerel, Devonport. The adjudicators have ventured to express their satisfaction with the very great merit and ability displayed in several of the remaining essays. The committee are making arrangements for the immediate publication of the successful essay. The essay will be published at the lowest possible wholesale price by Messrs. Bentley, of Fleet-street, price 15s. per hundred. It is proposed to

present a copy to every member of the Legislature. The committee recommend that the provincial Chambers of Agriculture should circulate copies in every parish within their respective counties. All those who feel interested in this most important question could greatly aid the efforts of the committee by purchasing and distributing copies of the essay amongst the ratepayers in their immediate neighbourhood. The committee recommend that Mr. H. Masfen, Mr. Arthur Starin, and Captain Craigie be added to the executive committee. They also strongly urge that the Chambers of Agriculture which have not already appointed any gentleman to represent them on the Local Taxation Committee should do so at the earliest opportunity. The committee have prepared a form of petition, which they propose to forward to every provincial Chamber of Agriculture, trusting that the members of those chambers will use their utmost exertions to obtain as great a number of signatures as possible. They further recommend that the petitions should be forwarded by each chamber to its local members of Parliament for presentation. The following are the clauses of the petition:

That the direct tax of over eleven millions per annum under the name of "poor-rate" bears exclusively and unjust on income arising from real property.

That the exemption from the poor-rate assessment of income arising from personal property is not only unjust, but also impolitic, and prejudicial to the public interest, and therefore requires the serious consideration of Parliament.

That the poor-rate and its mode of assessment, by costly and frequently incorrect valuations, discourages investments of capital in improvements, and thereby impedes industry and enterprise.

That the tax has an injurious bearing on house property in every city, town, and village, presses heavily on investing in buildings, especially on investments in improved dwellings for the working-classes, and limits the demand for the labour of skilled and unskilled artisans employed in the planning, ornamenting, and building of houses.

That indirectly this tax increases pauperism, lessens the employment of labour in the production of food, and thus inflicts a two-fold injury on the poor, who are especially interested in the increase of food and the increase of employment.

That investments of capital in improvements, tending to increase of food, to increase of dwellings for the poor, to increase of employment in skilled and unskilled labour, should not be discouraged by a special tax (averaging over 11 per cent.) on income arising from such investments.

That the general tendency of recent legislation having placed the management of poor and county rates under boards and auditors, controlled by a central power, has removed the objection that the maintenance of the poor and highways is a local duty, and therefore should be paid by a local tax.

That the majority of county and borough voters are ratepayers, but not generally large money owners, and are therefore deeply interested in the removal of the present exemption from poor-rate of income arising from money however invested or employed.

That the re-adjustment of local taxation is a question entirely removed from the domain of party politics, and is strenuously advocated by persons of any shade of political opinion.

The Committee will, it was added, be prepared at their next monthly meeting in March (having then been in existence twelve months) to present a statement of their accounts; but as they will have exhausted their funds at their disposal by the payment of the prize essay, with the publication and distribution of the prize essay, they feel that a large increase of their funds is absolutely necessary for carrying on their work with vigour and success.

A donation of £50 was voted on account of the prize essay. Some new members having been elected,

The CHAIRMAN said there seemed to be great difference of opinion as to whether farmers' horses employed in drawing a load of shingle, or any other material for the repair of roads, were or were not chargeable with licence duty. The decision rested with the surveyors of taxes, who, as they all knew, were almost certain to decide against the farmers; and at the meeting of the Business Committee on the previous evening it was proposed that either a deputation should wait upon the Chancellor of the Exchequer on the subject, or a question should be put to him in the House of Commons. He believed that in some cases where a farmer had fifteen or twenty horses, the whole were charged with duty unless it were

shown that one of them was specially used in drawing materials for repairing the roads. It was clear that that could not have been intended by the Legislature.

The Chairman was requested to put a question on the subject in the House of Commons.

The CHAIRMAN said: The next thing on the agenda was a proposal that a deputation should be sent to the Chancellor of the Exchequer, to ask him whether free trade was to be applied to the Englishman as regarded the malt-tax?

Mr. C. S. READ, M.P., said: He would move that a deputation wait upon the Right Hon. gentleman, if possible, directly after the Council meeting in March, adding, that unless it went before the budget was proposed, there could be little chance of success.

Sir G. JENKINSON, M.P., seconded the motion.

Mr. HODGKIN thought, that unless there were a large surplus this year, there was but small hope of their being more fortunate than they were on previous occasions.

Mr. NEILD trusted that there would be no faint-heartedness in the matter. The time had come when agriculture must be unhackled, and set free at home, and the malt-tax, like many other imposts, showed the injustice inflicted on farmers in their race with the rest of the agricultural world. Mr. Cobden once said, that if the county members were united in urging the necessity of the abolition of the malt-duty it would soon be abolished.

It was then resolved, that a deputation be organised at the meeting in March, to wait upon the Minister.

The meeting next proceeded to consider the subject specially appointed for discussion, viz., "The best mode of providing for the future maintenance of turnpike trusts and highways."

Mr. JARREY TURNER (Peterborough Chamber) introduced the following resolutions: 1. "That as hardship and injustice have been inflicted upon many parishes by the partial abolition of turnpike trusts, and as the policy of continuing some trusts by annual legislation is temporising and unsatisfactory, this council is of opinion that all turnpike trusts should be abolished simultaneously, and that the maintenance of all public roads should be settled on a permanent and equitable system." 2. "That, as the interests of the whole community have been promoted by the existence of the improved means of traffic and intercommunication, and as much of the expenditure in the formation of turnpike roads was incurred to facilitate the mail service, to provide for the transport of troops and military stores, and for other imperial purposes, it would be unjust to charge the remaining debts upon rateable property only; and that these debts ought to be liquidated by the national exchequer." 3. "That, as it would be unjust to transfer the burden of future maintenance of the turnpike or trunk roads of the kingdom from the present users of these roads to the owners and occupiers of rateable property, this council considers indispensable either a revision of the rating system, so as to bring under contribution the general wealth of the districts through which the roads pass, or the alternative of part payment of the road expenditure out of the imperial revenue." After remarking that these resolutions were almost identical with some which had been passed by this Chamber, he cited a resolution of the Norman-Cross Highway Board in his own district, passed in reply to a circular from the Secretary of State, asking for the opinion of such bodies, to the effect that the new system had given great dissatisfaction to the ratepayers generally on account of the additional cost, which had not been counterbalanced by the advantages; the board also, recommending a return to the system established by the Act of 1835. He added that he would then confine himself to moving the first of his three resolutions.

Mr. CALDECOTT (Rugby) seconded the resolution.

Colonel WILSON (Suffolk) said a board in the western division of his county had after six and a-half years' trial sent a reply to the Government circular, expressing its unanimous approval of the Highway Act. When that Act was first introduced the ratepayers in that district were by no means satisfied, fearing that it would lead to great additional expenditure, but it was now generally approved. He believed that nearly all turnpike trusts would come to a natural death unless they were kept alive by the Turnpike Continuance Act; and if he were right in assuming that the money was lent for so many years with the expectation that it would be repaid at the end of that time, the people who lent it had no more claim

upon any one in case of failure than a person would have upon the Stock Exchange if he made what turned out to be a bad investment. As regarded the maintenance of roads in future, it was suggested that the cost should be borne partly by the Government. They all knew that the incidence of taxation was now unjust; but he would caution the Chamber against anything which would increase the present array of Government inspectors. There were inspectors already for almost everything, except highways, and let them keep clear of them if possible in that case. In his opinion the best arrangement would be for each parish to maintain its own roads.

Mr. JANCEY (Herefordshire) doubted whether an increase of area would conduce to good management; but until there was a readjustment of local taxation they had a right to ask the Government and the public to pay something towards the maintenance of roads.

Mr. GENGÉ ANDREWS hoped the Council would never assent to the principle that it would be fair and just to repudiate turnpike debts. No doubt the lenders of the money thought at the time that it would be as secure as money in the Funds, and he deprecated that repudiation which had disgraced other countries.

Col. WILSON said he should be the last person to suggest repudiation, but he wished to know what was the legal status of the holders of the debts.

Sir G. JENKINSON, M.P., said he had drawn up an amendment, which he believed embraced the pith of all the resolutions submitted to the meeting. His view in proposing it was not to weaken any recommendation of the Council, but rather to induce it to look the facts in the face, and not to ask for anything which was sure not to be granted, and the asking for which would tend to stamp them as not being men of business. Any attempt to reimpose turnpikes where they had been abolished must be perfectly futile; they might as well attempt to reimpose protection. The amendment which he had to propose was as follows:

"That in the opinion of this Central Chamber of Agriculture the question of the future maintenance of turnpike roads and highways is mixed up with, and dependent upon the larger question of the re-adjustment of local taxation. But subject to this proviso: This Chamber considers that the injustice and hardship inflicted on various parishes by the system now in force of the partial abolition of trusts, and by the expense of the maintenance of the turnpike-roads of the trusts so abolished, being borne by the parishes only through which such turnpike-roads pass should be put an end to without delay. To effect this it is expedient that the Legislature should enact: 1, That the abolition of all remaining trusts should be immediate and simultaneous. 2, That the Highway Act should be made general and compulsory. 3, That the area of liability for the expenses of maintaining turnpike-roads and highways should be spread over all the parishes included within each highway district as a common charge, according to the rateable value of each parish."

As regarded his proposal, that the Highway Act should be made general and compulsory, he believed that the evils which were complained of arose chiefly from the permissive character of the Act, and that what he proposed pointed to the hardships of the existing system, and would supply a remedy.

Mr. GENGÉ ANDREWS had great pleasure in seconding the amendment, because in providing for the maintenance of roads it expanded the area of rating. He thought that unless they could insure that the area of rating should be extended to personal as well as real property they would make a great mistake if they consented to the abolition of tolls.

Mr. WESTOVER (Banbury) objected to the Highway Act being made compulsory.

Mr. R. N. GREVILLE, M.P., believed there was great difference of opinion with regard to the working of the Highway Act. He lived in the middle of a county which was one of the first to adopt it, and there the roads were now generally better and almost invariably more expensive.

Mr. KNATCHBULL-HUGHESSEY, M.P., must say that, occupying as he did a very subordinate position in the Government, it must not be supposed that he was able greatly to influence or affect its policy. He appeared there, not as a representative of the Government, but rather as one who, being a landowner and a land occupier to a considerable extent himself, was desirous of obtaining rather than giving informa-

tion on a subject which was interesting to them all. He would frankly state that one of the reasons why he was present was, that a mistake had crept into the newspapers which he was anxious to correct—namely, that that question was to be brought before the House of Commons during the present session. A promise was, indeed, given to that effect; but unfortunately the present Government had, like previous ones, promised to do more than could be accomplished; and although he had urged strongly upon the Government the importance of that question, he found that it was necessary to postpone a measure which he had hoped to propose at once. There was to be an announcement in the Queen's Speech that day—he hoped he should not be charged with betraying secrets because he referred to it—which bore upon the solution of that and other questions affecting the agricultural community. It would be announced that day that the question of rating was to be considered, and a measure proposed relating thereto; and he need not remind those who had studied the matter so long, so anxiously, and so zealously, as many gentlemen present had done, that the question of rating was, like one or two other questions, inseparably mixed up with that before the meeting. Now, upon the question under discussion he wished to speak with the utmost frankness. He hoped it would be clearly understood that in anything he might say as to the best solution, he was expressing only his individual opinion, and that if the result should not precisely correspond with what he sketched out, neither he nor his colleagues would be afterwards accused of having given a "pledge that was not borne out by the event. The first resolution before the meeting declared "that all turnpike trusts should be abolished simultaneously." He must say that he was a little staggered at that proposition. No doubt the simultaneous abolition of all turnpike trusts would in some respects be advantageous; but, considering the different positions of those trusts—that some were heavily in debt and others almost out of debt; that some were steadily paying, and others had no hope of paying—it was evident that any measure which simultaneously abolished all trusts, or dealt with all on the same footing, would inflict even greater hardships than it would remove. As regarded what had been said in that discussion about the bondholders, no doubt the speaker was logically right. Logically, it was evident that if a person put his money on a terminable security he had no right to expect that when the time arrived for payment of the principal he would be placed in so favourable a position as if he were entitled to a renewal of the term. That principle was part of the common law of the land. As a simple, dry matter of fact the bondholder in the case in question had no legal claim whatever. What constituted the peculiarity of the case was that Parliament had from time to time renewed the Acts, and that such renewal for periods of 10, 20, or 30 years, had created a species of confidence that could not otherwise have existed. It would, therefore, he thought, be rather hard to deal with the parties concerned as though no expectations of renewal had been excited. Some persons might contend that the deficiency in this case should be met out of imperial resources. He did not think any Government or Chancellor of the Exchequer could propose such a measure with any hope of success. In the first place, it might be said, and said truly, that considerable hardship would thus be inflicted on that large body of bondholders who had, from one cause or another, already consented to receive a much smaller amount than they were entitled to—that it would be very hard upon them for Government to step in and pay the debts of others after they had lost so much. Take his own case. He had been a bondholder. In one case he had regularly received the interest, and a portion of the principal had been paid off; in another he had been obliged to abandon his claim, and had got nothing; and in another, again, he received thirty per cent. in full satisfaction of the debt, and was glad to get it. He should have thought it rather hard if, for the benefit of other persons who held no better security, his own Parliament had stepped in and settled the debts—debts that remained. Therefore he thought that in any settlement which might be proposed relating to that matter the allocation of the debts would be found exceedingly difficult. Without pledging himself as regarded any future action, he wished to show how exceedingly difficult it would be to work out a question of that kind, especially how difficult it would

le to apply imperial taxation in the settlement of it. If the experience of those who had dealt with such subjects militated against the idea that any Government would propose what he had mentioned, surely it would be wise for them to dismiss such an idea from their minds, and not clog the discussion, as he perceived some chambers had done, with a resolution declaring it to be necessary that the Government should deal with this matter by means of imperial taxation. Now, with regard to turnpike trusts, there had been one mistake made that morning, which should, he thought, be corrected. A gentleman remarked that all the trusts were kept on by the Continuance Bills. That was by no means the case. About half the turnpike trusts had already been removed, and others were being removed from time to time, as circumstances seemed to require. He quite admitted that hardships were being inflicted. A great many of the remaining trusts were going, however, year from year, their term not having expired, and it was difficult to deal with some of them, except by putting a financial pressure upon them, which would be hardly fair. All this showed how complicated the subject was, and that it would not be so easy to abolish all turnpike trusts simultaneously, as some gentlemen appeared to suppose. He now came to the highways. Many gentlemen present might be aware that he had for years dealt with that subject as an independent member of Parliament, and had introduced two bills relating to it. He did not now tie himself, as it were to those bills; but he thought he might congratulate himself that they had awakened the country to a sense of the importance of the question. The country had now become alive to the fact that the question must be settled, and it was for them to bring their influence to bear upon it in such a wise and discreet manner that it would be settled satisfactorily to the agricultural community. His object had been to labour until he had obtained a uniform system of road management throughout the kingdom. It was absurd to have a number of miles of road over which there rode two surveyors amenable to different authorities, and two systems running side by side which inflicted a considerable burden on the country. Then came this difficulty, in the solution of which, however, would be found the ultimate solution of the whole question, namely, that turnpike roads did not stand in relation to the general traffic of the country as they used to do, that was to say, as being the main arteries of traffic, but that, partly from the interruption of railways and partly from other causes, turnpike roads and highways had become so intermixed that many highways were more used than turnpikes; whilst with regard to turnpikes there were many that were now no more than an inferior description of highways. The resolution justly said that these roads were made for the interest of the whole community. But a distinction must, nevertheless, be drawn between those roads which were great arteries and those which were not, because there were throughout England a vast number of turnpikes which might become highways to-morrow, and it was quite possible and probable that there were some turnpikes, the maintenance of which ought not to be borne by the parish. What was wanted, then, was to decide the difference between the two, and some power to authorise, if necessary, a different payment for the support of the one from that which was made for the support of the other. The best solution was this: that as a general rule all highway districts should support all the roads within those districts, and that all the charges of a highway district, such district being well considered and defined, should be borne by a common and not a parochial fund. Then there should be a power to take out of the category of roads to be maintained by the district such roads as from circumstances ought fairly to be chargeable upon a wider area. By this he meant roads which were the main roads of the county—say, roads from one town to another, which it was evident the county ratepayers should be called upon to maintain; and another class of roads which lay near mineral districts, the heavy traffic of which cut up and made the roads very expensive, whilst the owners of the mines contributed a very small proportion towards their repair, although they were the means of doing the greater part of the mischief. His idea was, moreover, that the person who should determine what roads were to be taken out of the category of roads to be supported by the district should not be a stranger or Government inspector, but a person in some sort connected with the county (Hear, hear). This naturally

brought him to the question of county financial boards, and he believed that the Bill he introduced last session on this subject contained the germs of the settlement of that question; and that if they had, in those who managed the finances of the county, a board which commanded the confidence of the ratepayers, not composed of one class alone, but partly of *ex-officio* members and partly of practical men of all classes in the community, they would have formed a board as a superior referee, who would be able to decide satisfactorily what roads in the county ought to be thrown on the district and what on the larger area. They might also vest a controlling power in the Secretary of State to determine whether the roads named by the board should be supported out of the county rate; whether they were so national in their character as to constitute a fair demand upon the national purse for some portion of their maintenance; or whether there might not be some exceptional instances where, the roads being situated in a mineral country, it would not be necessary to keep up the old turnpikes and secure their maintenance by the persons who used them. But the broad principle was to divide the roads in some such way as he had indicated, taking those which were not really other than highways and supporting them by the districts; and taking the others which were proved to be out of that category and charging them upon a wider area. With regard to highway districts, that was a question upon which he was able to speak with some authority. The circular issued last autumn which had been referred to the himself had drawn up and was responsible for, although it had the sanction of the Home Secretary. It had been sent to the clerks of all highway boards, and the answers he had received to its inquiries enabled him to form an opinion as to the working of the Highway Act. Speaking of that Act, he had always entertained the opinion that permissive legislation was not likely to be satisfactory; that it was the duty of the Legislature, as the representatives of the people, to ascertain and decide what subjects required to be legislated upon, what the character of the legislation should be; and when the two Houses of Parliament had passed a law, and it had received the Queen's assent, it should be obeyed by the community. And his experience of the Highway Act had only confirmed his opinion, that permissive legislation was open to the gravest objections. When he sent out the circular referred to, he certainly expected to find that a preponderance of complaints would have come from the highway boards; but it turned out to be no such thing, for out of the 340 highway boards constituted, 178, or more than one-half of the whole, returned answers to the effect that the Act had worked satisfactorily to the ratepayers; that the roads were improved; that in some places there had been a diminution in the charge; and where it had increased, that increase had been far more than counterbalanced by the advantages of having good roads. With respect to the minority, about one-third of them had not returned any answers to the circular. Some of the remainder had replied to the effect that their boards had not been formed long enough to enable them to give an opinion; whilst only eighty had returned unfavourable answers. Out of that eighty, however, a very large proportion, more than one-half, had considerably qualified their answers. Some admitted that the roads were greatly improved, though they thought the expense too heavy; but they hoped that it was in course of diminution. Others, again, found fault with the surveyor of the district; but, after all, a good deal of the disapproval expressed might be traced to the fact that the Highway Act was a permissive not a compulsory measure. These figures proved, he thought, that the Act could be worked well, that it was a good and useful Act, and that, however unpopular it might be in certain districts, the matter would never be set right until, having rendered it more palatable to the minority who dissented from it, it was made compulsory over the whole country. The answers of many of the highway boards had contained very valuable information, and he should be glad if any gentlemen connected with those boards would convey to them his thanks and those of the deputation with which he was connected. The resolutions suggested many other observations, but he had given the Chamber his general ideas on the subject, and he could assure them that upon all the points on which he had touched it would be the desire of the Government to consult the wishes of the agricultural community, which must obviously be the class who knew more about the practical working of the matter than any one else (Hear, hear). He

could not then go into the question of rating, or pronounce an opinion respecting it in his present position. In fact, he spoke with his hands tied. Still he would deal with them with the utmost frankness; and if they would keep out of view those plans and projects which were not likely to be taken up by the Government, and confined themselves to that which was practical and sensible, he had no doubt a solution might be obtained which would be generally satisfactory. As to the debt, it had been reduced to a little over £3,000,000 at the close of the year 1868, and there was no doubt it was still slowly being further reduced. A great deal of it, however, it was hopeless to expect to reduce; but that question of the debt must be fairly tackled before they could deal with the whole question. If by getting rid of all turnpike roads they could reduce the expense to the ratepayers, although apparently increased by the charge for the reduced debt and repairs, they would do great good. That, however, would depend very much upon the identity of tollpayers and ratepayers, and it had been proved to demonstration before the Committees of the House of Commons that in many instances tollpayers and ratepayers were much the same people. In conclusion, the right hon. gentleman reiterated his desire and that of the Government to settle the question in a manner as satisfactory as possible to the farmers; for if satisfactory to them it must be so to the Government.

Mr. CORRANCE, M.P., was sure he was only expressing the feelings of all present when he said they were deeply indebted to the right hon. gentleman for his frank and unreserved exposition of his views on that subject.

Sir GEORGE JENKINSON, M.P., must confess that the arguments of the right hon. gentleman did not appear to him to support all his conclusions. He had spoken of the debts as the great obstacle to a settlement of the question, but he (Sir G. Jenkinson) did not see what those debts had to do with the question of the future maintenance of roads. The right hon. gentleman said they should aim at establishing a uniform system. He accepted his proposition. But what was the uniform system under their notice? It was that of the highway districts, which he believed stood condemned ("No, no," and "Yes"). The right hon. gentleman had obtained from the Boards satisfactory testimony to their own efficiency, but it appeared from the returns that the expense, instead of having diminished as was expected, had increased; while in 18 counties from which he had seen the returns, there was only one—Northumberland—in which the cost of maintenance was not larger in the third year than in the second.

Mr. C. S. READ, M.P., said that after the full, cordial, and he must say most satisfactory explanation of the right hon. gentleman, he would appeal to Sir George Jenkinson to withdraw his amendment, in order that the Council might pass a resolution to the effect that, until they had seen the Government Bill with regard to rating, the subject had better be postponed.

Sir MASSEY LOPES, M.P., thought they would be unanimous in thanking Mr. Knatchbull-Hugessen for attending the meeting, and so ably explaining his views. He should also have risen at once to move an amendment like that just suggested, but that he thought it might be considered desirable that the deputed members of Chambers should have an opportunity of representing their opinions on the question. He was very much gratified by the announcement the Government were going to deal with the subject of local taxation, and he agreed with the right hon. gentleman that the question before the meeting was part and parcel of that much larger question. He would now move, "It is the opinion of this Chamber the present system of turnpike tolls, it would be inexpedient and impolitic at present to adopt or recommend in lieu thereof any proposal which may in any degree tend to increase the expenses of our so-called local burdens, until the Government have announced their promised scheme for dealing more comprehensively with the whole incidence of this important subject."

Sir G. JENKINSON, M.P., said, that in anticipation of what had just been said, he had been prepared to withdraw his amendment, and to substitute for it the following: "That after the statement made by Mr. Knatchbull-Hugessen, this Chamber considers it expedient to wait for the re-adjustment of local taxation before passing any measure having reference to the future maintenance of turnpike roads and high-

ways." He thought that would exactly meet the view expressed by Mr. Read.

The Hon. Baronet then withdrew his amendment, and that of Sir Massey Lopes, M.P., which took its place, was seconded by Mr. Neild.

Mr. Jabez TURNER said, as the proposer of the original resolutions, he thought he should best promote the object which he had in view by withdrawing them.

The original resolutions were accordingly withdrawn.

Mr. GEORGE ANDREWS contended that as all persons were benefited by good road communications, the whole community ought to contribute towards their maintenance.

Mr. WHITAKER (Worcestershire) spoke of the dissatisfaction with the working of the Highway Act in that county.

Mr. SMYTH (Hertfordshire) said the effect of the Act in his district had been to double the rate and create great animosity. Among the ex-officio members of the highway board were the landlord, the brewer, the banker, and even the coal merchant. If the question of local taxation were satisfactorily settled, all the difficulties with regard to roads would vanish.

Mr. G. F. MUNTZ (Birmingham) supported the amendment. The amendment of Sir M. Lopes was then passed unanimously.

Sir M. LOPES observed that he thought it would be desirable to discuss the question again after they had learnt what was the Government measure with regard to local taxation.

Mr. GEORGE ANDREWS said though he was glad to hear the right hon. gentleman's announcement, he could not join in the clapping of hands which followed it. He should like to see what the Government measure was before he clapped his hands.

Mr. KNATCHBULL-HUGESSEN said in order that there might be no mistake, he wished to repeat that he spoke as a private individual and not as a member of the Government. What he said was that he had heard that the question of rating was about to be dealt with by the Government and that a measure was prepared, but that, not being a Cabinet minister, he had not seen the details, and therefore gentlemen must not be disappointed if it fell short of what they hoped for.

The following resolution was proposed by the business committee: "That agricultural returns, as at present collected, are unreliable and unsatisfactory; that it is desirable for such returns to be made once in ten years; and that they should then be compulsory."

Mr. CHARLTON (North of England Chamber) read a resolution of that Chamber, declaring that agricultural statistics would be very valuable for agricultural and national purposes, provided they were fair and reliable; but that as at present collected they were useless, and were employed for individual injury.

Mr. D. LONG said he was inclined to move as an amendment "That the only advantage of the collection of agricultural statistics would be to keep down the price of agricultural produce by importations from abroad when there is a deficiency at home, and such collection consequently would be not only most inquisitorial, but unjust and prejudicial to the interests of agriculturists." Statistics collected every ten years would not be open to the objection thus described, because farmers would not be continually interfered with, and they might be of advantage without the drawback of their being used for improper purposes.

Mr. NEILD thought the day was come when England must keep pace with other countries, and have true and regular accounts of its agricultural products. It was not agricultural statistics, but the mismanagement of them that had led the merchants of this country to import double the quantity of corn this year that they should have done. As to the proposal to collect statistics every ten years, that was simply a polite way of burking the whole question. He had intended to propose the substitution of ten for three years; but in deference to Mr. Read, whom he was always happy to follow, he would propose that the period should be five years.

Capt. CRAIGIE seconded the amendment.

Mr. C. S. READ, M.P., said it appeared to him utterly senseless to suppose that the simple publication of the fact that a few thousand acres more or less were under cultivation, would affect importations to any extent, or regulate the transactions of their merchants. It was the yield, and not the number of acres sown, that showed what was grown. He did

not think agricultural statistics did either the harm or the good that many persons in that Chamber seemed to think.

Mr. A. PELL, M.P., observed that the returns which many persons had been so anxious to obtain were not placed in the hands of the merchants until their orders had been given, and the corn was on its way to this country. Imperfect and useless as they were, however, they cost £16,000 a-year, and therefore, even in the economical point of view, a quinquennial, and still more a decennial, collection would involve a great saving of the public money. What was wanted was information which would show whether or not England was changing the character of its cultivation; whether it were becoming more of a grass-growing or a corn-growing country, and whether as regarded the production of meal it was able to rely upon its internal, and was less dependent on foreign resources. Such statistics the nation might fairly demand at their hands.

Mr. WEBB thought five years preferable to ten.

Mr. JAMES TURNER remarked that the uselessness of the present system was evident, from the fact that 14,000,000 quarters of wheat were imported last year when only 8,000,000 were required.

Mr. H. WOODWARD ridiculed the idea that statistics, collected only once in ten years, could be of any use, adding that no one could expect to see them more than five or six times in his life.

Mr. SMYTHIES thought the real ground of complaint was

the permissive character of the present system, and remarked that if statistics were collected only every 10 years, farmers would have forgotten what they had learnt (laughter).

On the question being put, the amendment substituting "5" for "10" years was rejected, and the latter figure was then adopted by a large majority.

Mr. SMYTHIES proposed another amendment to the effect that the collection be annual and compulsory.

Mr. YOUNGMAN seconded the amendment.

Mr. NIELD expressed a wish to have it declared, that agricultural returns as at present collected, are unreliable and unsatisfactory, and that they should be made annual and compulsory.

The CHAIRMAN said he desired to understand what was the question to be submitted. Was it meant to declare that agricultural returns, as at present collected, are unreliable and unsatisfactory; and that, therefore, they should be made compulsory?

After some conversation, the amendment was put from the chair in the following form: "That agricultural returns be annual and compulsory?" Seven hands were held up for this amendment, and 11 against it. The original resolution was then put, and, to the no little surprise of many persons in the meeting, negatived by a majority of one!

A vote of thanks was given to the Chairman, and the meeting then separated.

THE PROGRESS OF THE SESSION.

Speaking last week to the opening business of the Agricultural Session, we said "the more important of these meetings would seem to have been already held, as nothing very particular would promise to come of the discussion at the Farmers' Club, and as nothing very particular does ever come of the deliberations of the Central Chamber of Agriculture." It must be admitted, however, that any such anticipations have not been altogether realized. The question of breaking up grass land had so often already been under the consideration of the Farmers' Club, that it was doubtful whether the same subject would be found to command much further attention. The result was certainly something of an agreeable surprise. Those who have the opportunity of referring to the occasions on which this matter had previously been discussed by the Club will find that it was never so well handled. Mr. Cadle's hurried delivery was rather against him, and no doubt his address will tell better to the eye than it did to the ear; for it is a carefully prepared, well-balanced, and eminently practical paper, while the debate which followed was one of the best, in the way of close and sound criticism, that has happened here for some time. It embraced in a very felicitous degree all the advantages of a comparison, as each succeeding speaker might be said to represent a certain district or system of his own; and we would only repeat that the report which we give in full may be studied with equal benefit by those who were absent as by those who "assisted" at the proceedings. According to our contemporary *The Gardener's Chronicle*, "Mr. Cadle read a capital paper, which was listened to throughout with the greatest attention by a large agricultural audience, and an interesting discussion ensued." We might, perhaps, be inclined to put more value on the discussion than is here quite inferred, for with the exception of one speaker, who told the Club to "turn over a new leaf" in the selection of its subjects, and who was very happily corrected by the Chairman, there was not a member but who spoke with effect.

But we must hold more strongly to our line when declaring that "nothing very particular does ever come of the deliberations of the Central Chamber of Agriculture,"

for, as it really seems, scarcely anything came of the meeting on Tuesday. There were two especial questions under discussion, the one turning on turnpikes and highways and the other on the collection of agricultural statistics, and on neither was any conclusion whatever arrived at! This sounds strangely, too, for the local Chambers have been passing their opinions on the highways until they have fairly tired of passing any more; as, if there be anything on which the Central Chamber particularly prides itself, it must be its resolutions, and even here resolutions were as plentiful as blackberries. Thus Mr. Jabez Turner moved the following formidable series, that we give more as a curiosity than anything else: "That as hardship and injustice have been inflicted upon many parishes by the partial abolition of turnpike trusts, and as the policy of continuing some trusts by annual legislation is temporising and unsatisfactory, this council is of opinion that all turnpike trusts should be abolished simultaneously, and that the maintenance of all public roads should be settled on a permanent and equitable system." 2. "That, as the interests of the whole community have been promoted by the existence of the improved means of traffic and intercommunication, and as much of the expenditure in the formation of turnpike roads was incurred to facilitate the mail service, to provide for the transport of troops and military stores, and for other imperial purposes, it would be unjust to charge the remaining debts upon rateable property only; and that these debts ought to be liquidated by the national exchequer." 3. "That, as it would be unjust to transfer the burden of future maintenance of the turnpike or trunk roads of the kingdom from the present users of these roads to the owners and occupiers of rateable property, this council considers indispensable either a revision of the rating system, so as to bring under contribution the general wealth of the districts through which the roads pass, or the alternative of part payment of the road expenditure out of the imperial revenue." And, next, of course, Sir George Jenkinson moved as an amendment another neat little thing in this way: "That in the opinion of this Central Chamber of

Agriculture the question of the future maintenance of turnpike roads and highways is mixed up with, and dependent upon the larger question of the re-adjustment of local taxation. But subject to this proviso: This Chamber considers that the injustice and hardship inflicted on various parishes by the system now in force of the partial abolition of trusts, and by the expense of the maintenance of the turnpike-roads of the trusts so abolished being borne by the parishes only through which such turnpike-roads pass, should be put an end to without delay. To effect this it is expedient that the Legislature should enact: 1, That the abolition of all remaining trusts should be immediate and simultaneous. 2, That the Highway Act should be made general and compulsory. 3, That the area of liability for the expenses of maintaining turnpike-roads and highways should be spread over all the parishes included within each highway district as a common charge, according to the rateable value of each parish." And, then the meeting, after weighty deliberation, resolved to reject alike the original series and the second series of motions, and to express no opinion whatever! This energetic determination was said to be due to the presence of Mr. Knatchbull Huggessen, who was very careful to have it understood that he did not come there as a representative of the Government, and that he did not mean to say what the Government was going to do. Personally, he objected, moreover, to the point of the Council's own series of resolutions; and so he was loudly cheered, "the meeting was deeply indebted to him for his unreserved exposition, his full and cordial explanation," and so forth; although it certainly does seem to us, as it struck Mr. Genge Andrews, that before they begin to holla they should have some notion of what they are hollaoing about.

Thus having so satisfactorily disposed of one subject, having brought all the influence of the Central and local chambers to bear upon the Government in the arrangement of its measures by doing and proposing to do nothing whatever, the meeting proceeded to deal as determinedly with the second question before it. The Business Committee, taking its cue from Mr. Sewall Read, declared "That agricultural returns, as at present collected, are unreliable and unsatisfactory; that it is desirable for such returns to be made once in ten years; and that they should then be compulsory." Whereupon, Mr. D. Long moved as an amendment "That the only advantage of the collection of agricultural statistics would be to keep down the price of agricultural produce by importations from abroad when there is a deficiency at home, and such collection consequently would be not only most inquisitorial, but unjust and prejudicial to the interests of agriculturists." Mr. Smythies moved for *free* instead of *ten* years in the original motion, and then that "Agricultural returns be annual and compulsory." The first, or Mr. Long's amendment, would appear never to have been put, although duly seconded; the proposition of five for ten years was rejected by a large majority; that for annual and compulsory returns was lost by 11 to 7; and the original motion was also lost by one vote! The consequence of this, as our reporter explains in a note, is that nothing whatever was carried, "to the no little surprise of many persons in the room." When the Government becomes naturally anxious to know what that influential body the Central Chamber of Agriculture would recommend as to the Amendment of the Highway Acts the answer is, "We would rather leave it with you for the present;" or, as Sir George Jenkinson said at Gloucester, Mr. Huggessen looking to the stand made by the Central Chamber may report that "not a single suggestion has been offered." And when the Government, again, would wish to ascertain whether the experiment of collecting agricultural statistics should be continued the Central Chamber

has really nothing to say about such a matter one way or the other. Mr. Sewall Read may say elsewhere as much as he likes about his ten years' plan, of course but another notion of "this day six months," but he must always bear in mind when doing so that this proposal has been condemned by the Central Chamber.

Was there ever such a shilly-shally, timid, trimming, much-ado-about-nothing business as this? Let any man read through the report of the proceedings and see how much he can make for himself out of it. The Queen's Speech says: "Bills have been prepared for extending the incidence of rating, and for placing the collection of the large sums locally raised for various purposes on a simple and uniform footing; for the amendment of the laws which regulate the grant of licences for the sale of fermented and spirituous liquors; and for facilitating the transfer of land;" while two or three Game Bills have already been introduced. And what is the Chamber of Agriculture going to do? The Chairman is to put a question as to the duty on cart horses, that he most probably never will put; a deputation is to put a question as to the repeal of the Malt Tax, and a petition for the re-adjustment of local taxation is actually to be presented, as well as a prize essay to be published. An admirable production, no doubt, this is, although the point of the report would go to sending round the hat again, "the Committee has exhausted its funds," and more money is "absolutely necessary." Here, in touting for more money, we are quite ready to allow the immense energy displayed by the executive of the Central Chamber.

And in all this we fail to see, as we have failed to see, any especial advantage arising from the offices of the Central Chamber of Agriculture. It may tend to serve the purposes of some few people, and make the world more familiar with the powers of honourable gentlemen of the calibre of Sir George Jenkinson, Mr. Pell, and Mr. Corrance. But to what end is the thing working? What good is it doing? What action is it taking? Are we to turn to the report of last Tuesday's proceedings as the answer? On the day following there was a dinner of the Peterborough Chamber, at which Mr. Attenborough was called on to propose the Central Chamber, and he did so after this fashion: "We had heard a good deal about the Central Chamber, but he did not think much about their doings on the previous day." Precisely so. We have heard a great deal about the Central Chamber, as everybody must have heard, but we do not think much of its doings. Mr. Attenborough is evidently a gentleman of a very nice observation.—*Mark Lane Express*.

MR. WYKEHAM MARTIN'S GAME LAWS AMENDMENT BILL.—The following are the chief clauses of this Bill: From and after the twenty-fifth day of September one thousand eight hundred and seventy it shall be lawful for any tenant, or any person employed by him, and having his authority or permission, to kill rabbits on the lands occupied by him, any agreement or covenant to the contrary notwithstanding; and any agreement reserving the sole or exclusive right to kill rabbits shall be null and void. Any person who shall kill any rabbits in pursuance of this Act shall not thereby become liable to pay any assessed taxes, nor shall he be bound to take out any licence under the Act passed in the twenty-third and twenty-fourth years of the reign of Her most Excellent Majesty, chapter ninety. The provisions of this Act shall not apply to any lands held under any lease which was originally granted for a term of years not less than five, during the term or currency of such lease.

THE CENTRAL FARMERS' CLUB.

GRASS LAND.

The first monthly meeting of the Farmers' Club in the present year took place on Monday evening, Feb. 7, at the Club Rooms in the Salisbury Hotel, the Chairman of the year, Mr. J. HOWARD, M.P., presiding, the attendance being a full average. The question fixed for consideration was "Grass land—when to be profitably broken up, and when more profitably kept in pasture," the introducer being Mr. CLEMENT CADLE, of Gloucester.

The CHAIRMAN said: Gentlemen,—I think I may very fairly congratulate the Club upon the importance of the subjects which have been selected for discussion during the coming year. Not only are the subjects important in themselves, but the names appended to them are those of men who are well known and who will, the Club may rest assured, handle the topics entrusted to them in a masterly manner. The subject to be introduced this evening is "Grass land—when to be profitably broken up, and when more profitably kept in pasture." Most of the gentlemen present are aware that Mr. Cadle has already won his spurs on this question, having received the first prize for the best essay on the management of grass lands from the Royal Agricultural Society of England (cheers). I am quite sure that if he can tell the members of this Club, and the farmers of England, how, with wheat at 5s. a bushel, they can turn any portion of their farms, or the landlords of England can turn any portion of their estates, to better purpose in increasing the supply of meat for the millions of our population, he will confer very great benefit upon the community at large (Hear, hear). You will have observed, gentlemen, that the month of May has been left vacant in the card. That is not because subjects for May have not been proffered for discussion. Several have been proffered, and I may state that no less important a man than Professor Voelcker has very kindly offered to read a paper; but, seeing that a very important question is to be introduced in another place which deeply affects the interests of agriculture—namely, the question of the education of the rural population, combined with that of the education of the whole country, it has been thought desirable that we should leave a month open for the discussion of any measure of that kind which may be brought before Parliament; and hence it is that you see a blank space in the cards for the month of May (Hear, hear). Without making any further remarks, I will call on Mr. Cadle to introduce his paper (cheers).

Mr. CADLE said: Mr. Chairman and Gentlemen,—At a discussion in this room some twelve or fourteen months ago, resulting from Mr. Mechi's paper on the undeveloped power of British agriculture, I heard some rather conflicting opinions expressed by members of this club as to the desirability of converting grass land into tillage, and as in the present day every thing that tends to the increase of farm produce is entitled to consideration, I thought a discussion on the subject would be very desirable, especially as the subject has not been brought before the Club for fifteen years, when Mr. J. Wood, of Ockley, Sussex, introduced "The expediency of converting grass land into tillage." The result of that meeting was that the following resolution was adopted, viz., "That this Club is of opinion that grass land of fair quality will be found most profitable in that state, but that inferior pastures would yield more profit to the occupier, a greater rent to the landowner, and more food to the community, if converted into tillage." Mr. Wood, by very

elaborate figures, showed the profits in arable over those of grass to be £1 18s. 9d. an acre per annum, and said that cattle may be profitably kept under cover; and in the course of the discussion Mr. Paine drew the line at 25s. per acre rent, under which value land might be profitably converted to tillage. In 1847 the subject was also before your Club, when it was introduced by Mr. Shaw, jun.; and the chairman, the late Mr. Fisher Hobbs, in opening the meeting, amongst other remarks, said, "Amongst practical men there can, I think, be but one opinion of the importance of the subject. Those gentlemen who live in arable districts will agree with me that in travelling throughout the country we cannot but feel surprised at the vast extent of grass lands we see, in comparison with the arable land. The greater portion of the grass land of this kingdom is moreover very badly managed. One-third of those grass lands are of decidedly inferior quality, and might be advantageously broken up and converted into arable land, thereby employing more than double the number of labourers producing more stock—that is to say, more beef and mutton—and at the same time go through its rotation in growing green crops." Mr. Shaw brought forward some very conclusive arguments in his paper, followed by a good discussion, in which the late Mr. Hudson stated that he had a good deal of experience, and that *such land broken up would produce more beef and mutton in two years than it would as pasture in four*. Mr. Turner also stated that he had broken up land that had produced more of the necessities of life in three years than it had previously in twenty as pasture land. The following resolution was arrived at: "That it is the opinion of this meeting that a large portion of the inferior grass land of this country might be broken up and brought into cultivation to the advantage of the landlords, the cultivators, and the labourers of England, by greatly increasing the employment, food, and wealth of the kingdom." In 1846 the subject was also before the Club, introduced by the late Mr. R. Baker, of Writtle, when it was decided "that many descriptions of grass land would be best brought into cultivation by the system of paring and burning, provided root crops be first taken; but upon the richer soils it is doubtful whether the object may not be effected by the ordinary method of cultivation." As will be gathered from the resolution, the paper and the discussion turned principally upon the best way of breaking the land up but during the discussion Mr. Hobbs said he had a field for which he could afford to pay the landlord double rent, if allowed to break it up. I will now endeavour to give you my views, and it is with the desire and expectation of hearing your more experienced and practical opinions that I venture to address you this evening. Long before I became a member of your Club I took great interest in your transactions, and was greatly struck with the practical nature of your papers and discussions. In treating the subject on the paper, "On grass land: when it can be profitably broken up, or when more profitably kept in grass," I will take the last part first, and show the class of meadow or pasture land that I consider may be most profitably kept in grass, and then show that which may be more profitably converted to tillage, and then give a medium course of treatment. As you will see, I only give general rules, for, as you are aware, in dealing with such a difficult subject, it is impossible to lay down any rule that

shall not have many exceptions, in consequence of the varying circumstances, therefore circumstances must be the guiding-star in deciding the question. For example, arable land in one part will grow forty, and even fifty bushels of wheat to the acre, whilst in another it will not grow twenty-five; or it may grow forty tons of mangolds, while other land with difficulty grows fifteen. The class of land that may be most profitably kept in grass is—first, the feeding or fattening lands, where cattle or sheep will become fat during the summer months without the aid of artificial food; secondly, where the grass land is not more than one-fourth the area of the farm; thirdly, stiff heavy soils that will not carry sheep to consume the roots on the land if converted to arable; fourthly, some of the shallow pasture land having only a few inches of soil; and, fifthly, those hilly fields that would be so expensive to work as tillage. **FIRST:** The feeding and fattening lands, where cattle and sheep will become fat during the summer months, without the aid of corn or artificial food. This class of land is no doubt the most profitable that a farmer can have, as it yields him a greater return, with less trouble and expense. It is more sought after, and commands a higher rent than any other class of land similarly situated, and therefore I would not propose breaking it up; but a good deal may be done in the way of its improvement. Perhaps the greatest evil this class of land (taking all districts) has to contend with is floods; and, although much has been done by the passing of the Land Drainage Act (1861), which enables landowners to combine together to remove water-wheels and other obstructions to the free passage of the water, and the land on streams and rivers has been improved thereby, still we want more facilities to be given, so that it may become more general. Drainage is also a means of great improvement, although much care must often be exercised not to over-drain it—it is sufficient to remove the stagnant water. It is not requisite to dry it quickly, as in the case of arable land; therefore the deeper the drains, and the wider apart they are—provided the stagnant water is removed—the better. Many thousands of acres of this class of land have not been drained for want of an outfall; but this can now be generally provided, as far as adjoining proprietors are concerned; and where sufficient fall is not supposed to exist, on careful examination more is often obtainable than was thought possible to be got. Where the expense is too great to remove mills, the land above might often be under-drained, and arrangements made for a portion of the water-power to be used in pumping such under-drained land. Irrigation may also sometimes be adopted for improving this class of land, and many other modes, which would extend my paper to too great a length, if entered into, such as renovating with fresh grass seeds, manuring, &c. **SECONDLY:** Where the grass land is not more than one-fourth the area of the farm. Here a good deal of caution is requisite before coming to the conclusion that any may be profitably broken up, although in some cases it may. I should prefer in this case to try and improve it in its present state by manuring, renovating with fresh grass seeds, consuming roots upon it, irrigation, and other modes of treatment; but in some places the land is so light, and has such a tendency to grow couch grass, that even this small portion of grass may be reduced with profit. One of the best ways of improving meadow land is to haul the roots and fold the sheep upon the meadows, in the same way as the arable land farmer would upon his tillage, giving them a fresh pen every day. By this means the meadow will be regularly dressed, instead of the sheep lying on those portions of the field that least require dressing, or in a road or some old hedge-row. This, with the consumption of plenty of corn or oilcake, is a certain way of improving meadow land. If straw is plentiful, it may be cut into short litter, and strewed about the pen each day, when it will be trodden into the land by the sheep; and if by this means the arable land is robbed of some of its manure, the increase in the hay crop will more than counterbalance it. **THIRDLY:** Stiff heavy soils that will not carry sheep to consume the roots on the land if converted to arable. It is not desirable to break up and convert to arable this class of land, except under particular circumstances; and sometimes it may be more profitably managed by a medium course of treatment, such as I will notice presently. Of course the great drawback to stiff, heavy soils is that you are so dependent on seasons for working the land to the best advantage; and if you grow much of that improving crop—roots, you have such difficulty and expense in hauling off the roots, that it makes a

material difference—so much so, that I should recommend trying to improve it as meadow land. Some fields of this class can be profitably broken up (if very well adapted) for wheat and beans, and also growing good mangolds. The consumption of roots as before mentioned, renovating with fresh grass seeds, boning, and other manuring may be adopted to improve it. Another mode is planting apple and pear trees; for, if the farmer could manufacture the materials he produces without restriction (sugar and spirits, for instance), a new era would dawn upon this class of pasture land. It appears to me that sugar can in no way be so cheaply produced in this country as upon the apple or pear tree. No seeding, hoeing, ploughing, manuring, &c., is required as in growing beet; the only expense is to plant the trees and pick the fruit. The principal drawback is that you cannot insure a crop every year; but ten or twelve tons of apples to the acre are no uncommon crop, and the value of these fruits is continually increasing, in consequence of the demand in the manufacturing districts. **FOURTHLY:** Some of the shallow soils that are only a few inches in depth. A good deal of the Down land comes under this head, and of this class of land I cannot say I have had much experience; but of course, if only three or four inches of soil is available, it is useless to attempt to make good tillage, although some of these light soils make very fair turnip and barley land, as on the Oolite (Cotswold Hills, for instance); and here the preferable system seems to be to lay it down to sainfoin for a term of years, and the quantity of sainfoin hay sometimes produced per acre is astonishing. **FIFTHLY:** Those hilly fields that would be so expensive to work as tillage. I have had a good deal of experience as to the expense of working hilly arable land, and my belief is, that the difference in the expense is never estimated high enough, for besides the extra labour to the horses you cannot get anything like the quantity of work of any kind done as you can where the land is level, especially in ploughing, hauling on manure, couching, and cleaning the land; but circumstances often do arise where this hilly land is so poor and bad that something must be done, and I will not take upon myself to say it may not sometimes be profitably broken up, especially where the larger proportion of the farm is pasture, but in all probability the medium course is preferable. I will now give the class of land that I consider may be profitably converted to tillage, but in dealing with this part of the subject I would remark that there are two great causes operating against the conversion of pasture land to tillage; first, that which I may almost call a prejudice on the part of landlords, who, having seen the abuse in days gone by from the farmer running the land out after breaking it up, and losing sight of the improved farming of the present day, forbid it altogether; and next from the increased capital required to manage it as tillage. In the former case I would call the landlord's attention to the great improvement made in arable land farming within the last 30 years to what has been made in pasture, and numbers of arable farmers that I know of spend a sum more than equal to their rent in artificial foods and manures, and some even double, so there is little fear of this class of men running their land out, especially if they are allowed at leaving for any unexhausted manures, improvements, &c., in which a landlord can well afford to do for the sake of the incoming tenant, for he may be sure it will be to his own advantage in more ways than one. With regard to the latter, it is of no use for any man now a-days to attempt to farm without sufficient capital, and it no doubt requires more capital to farm tillage to the best advantage than pasture. There is perhaps one other cause operating with landlords and agents in this matter and that is, the clause in almost all agreements of a penalty of in some cases £50 an acre rent for any old grass land that may be broken up without the landlord's consent. This is a very necessary clause to prevent an outgoing tenant doing a spiteful act, by ploughing up any old grass land, but to men who do not understand the nature of it, it appears, and in many cases is, so interpreted that it is put in agreements, because the grass land is so much more valuable, and it has no doubt misled many. A practical farmer writing in the *Mark-Lane Express* of June 24th, 1867, after showing the value of the turnip crop says: "If then the turnip, or rather the root crop is so valuable, why are farmers to be so closely restricted to certain courses or rotations of cropping? and why are such large breadths of moderate, not to say inferior grass lands to remain under pasture?" If modern culture and modern applications of manures and feeding stuffs

are worth anything beyond the old order of management—and no one disputes their worth—they would tell surprisingly upon the conversion of such lands into arable culture. They would thus be made to produce immense crops of roots, artificial grasses, and corn. Vast breadths of these soils would yield capital crops: first, of potatoes, then of wheat, next turnips, or other roots and esculents, *i. e.*, mangolds, swedes, carrots, and cabbages for stock; again potatoes, again wheat, and then clovers or seeds, followed by a corn crop, to be further supplemented by roots again, and so on continuously. This little island of ours ought to be the standing ground for fattening stock as food for the nation, and the importation and manufacture of feeding stuffs must be boundless. It must be made to grow more roots, more grasses, and more animal food. Ireland, too, is still better adapted for this order of management. Scotland grows splendid root crops. Who can tell to what amount our home supplies of animal food might come, or be made to extend?" Most other speakers and writers on this subject have gone into figures to prove the state of cultivation that is most profitable, but figures are so fallacious that I will not attempt to do anything of the sort, for an extra ploughing and cleaning, or an extra 5 bushels of corn would make a great difference in the estimate, and also because in a paper like the present it is impossible for listeners to follow figures; I will therefore take it as a fact beyond dispute, and to be admitted by every member of your club, that there are many fields of light pasture land to be found that would be far more profitable as arable. The point where disagreement would arise would be as that border line was reached, where it may be as valuable for one as for the other. I believe I should not have the least difficulty, if asked whether a field could be profitably broken up, in deciding whether it would be advantageous or not; but I confess to some little difficulty in explaining, or rather drawing the line of distinction for other people to comprehend it. There are so many points to be considered, many of them of such a slight and trivial nature, all to be taken into account before a decision for or against can be arrived at, that I hardly know how to enumerate them. However, some of them would be: adaptability to homestead and buildings—if the field is situate a long way off from this great desideratum for arable land, it would be a great drawback; then as to its growing corn—some land will not grow more than 20 or 25 bushels under any circumstances; then it may be very wet and difficult to drain, or it may be shaded by trees, or adjoining covers abounding with game. The temperature and rainfall has also an important influence as to the decision of converting grass into arable. Ireland, and some of the western counties get too much rainfall for growing wheat to the best advantage, while in many of the eastern counties they do not get enough to grow good roots. A rainfall of about 80 inches appears to be the quantity to enable both roots and wheat to be grown to best advantage. Temperature again, I believe, an important feature; it appears to be necessary to bring wheat fully to perfection to have a portion of the summer equal to a mean temperature of 60 degrees of heat, and situated not higher than 600 feet above the level of the sea; still, for our purpose many of the lands I would propose dealing with are under all the disadvantages mentioned capable of growing splendid roots and oats, and especially potatoes. The following may be enumerated as the most important sorts of land that may be profitably broken up—**FIRST**: The high and dry land that will carry sheep well, especially where the pasture land is more than half the area of the farm. **SECOND**: Where the pasture exceeds one-third or one-fourth the area of the farm. **THIRD**: The alluvial deposits or loamy soils by the river and brook sides, where the stream runs so rapidly that in the formation of the land only the coarser sand and gravel is deposited, and consequently the finer particles of clay so necessary to make up a good fattening soil are taken on by the floods to a more level space. **FOURTH**: Some of the loamy soils that will not carry sheep, where the land is convenient for buildings and the pasture exceeds half or one-third the area of the farm. **FIFTH**: The clay lands that will not carry sheep, but, when drained, grow the best of roots and plentiful crops of corn, and where the pasture exceeds half the farm. The **FIRST** on the list of pasture lands that may be profitably broken up is the high and dry inferior pasture land that will carry sheep well, especially where the pasture land exceeds half the area of the farm. Here much of the class of pasture is poor and dry, and principally grazed with sheep, which bite

the few fine grasses so closely that they are gradually lost, and from its tendency to grow couch grass the grazing with sheep increases this tendency and thus retards improvement, as they do not like to eat it unless it is kept very closely grazed, consequently it gradually kills the finer grasses. This is the class of land that may be most profitably converted to tillage, for roots can be grown and consumed on the land, and one acre of roots and one acre of clover or seeds, with the wheat and barley straw, supposing it to be farmed on the four course system, will keep a good deal more stock than four acres of the original pasture, and surely the acre of wheat and the acre of barley will pay for extra labour and capital. If the pasture land is one half the area of the farm, there can be no question as to the desirability of breaking up, especially as the roots can be consumed on the land by sheep. Under some circumstances the better class of lands may also be broken up with advantage. I have, myself, offered £95 an acre for a field of eight acres and £80 an acre for four other fields in the neighbourhood of my own farm, entirely as a speculation to break up; but of course this is an exceptional case, as it makes extraordinary good arable land. In the neighbourhood of Evesham and Pershore also, much very valuable pasture land is converted to tillage, combined with the growth of plums, &c. **SECOND**: Where the pasture land exceeds one-third or one-fourth only of the area of the farm. Here a little more consideration is necessary, for I consider one-third pasture to two-thirds tillage the most advantageous proportions to make the most of a farm. Still there are many cases that have come under my notice where even if only one quarter of the farm is pasture, some of that quarter may very profitably be converted, if the land is very good for growing roots and corn and bad for grass. Where sheep are the principal stock kept, there is not the necessity for so much pasture, as they can be kept in the summer on the clover and artificial grasses eked out as their keep now is by mangolds, corn, and cabbage during the summer months. **THIRD**: The alluvial deposits or loamy soils of the river and brook sides, where the stream runs so rapidly that in the formation of the land only the coarser sand and gravel is deposited, and consequently the finer particles of clay so necessary to make up a good fattening soil are taken on by the floods to a more level place. I have had some experience of this class of land, and where it is not very liable to floods, it makes some of the best tillage obtainable. On the banks of the river Wye, which is very rapid river, there is a good deal of this class of land, especially between Hereford and Ross, combining all the requirements for growing corn and keeping sheep, but which will not fat cattle, and would be doubled in value by being converted into arable land. Since writing the above, I am informed that a large landed proprietor, below Hereford, is extensively breaking up exactly the class of land to which I am alluding, but, I believe, more with the view of laying down again than as making tillage. **FOURTH**: Some of the loamy soils that will not carry sheep, where the land is conveniently situated near buildings, and the pasture exceeds one-half or one-third the area of the farm. This is a little different from the last class of land, inasmuch as the farmer has the expense of carting off the roots; still, under the circumstances mentioned above as to buildings and with a sufficiency left, some of the pasture may be profitably broken up to tillage, but more care is requisite than in the former cases. **FIFTH**: The clay lands that will not carry sheep, but when drained grow the best of roots and plentiful crops of corn, and where the pasture exceeds one-half the farm. This is the most difficult class to define, as to converting it into tillage for a permanency or not; still, if the pasture exceeds one-half the farm, it may often be profitably done where it is well adapted for stock and convenient to the homestead, and a further advantage may be gained by breaking some up and growing roots, these roots to be taken and consumed by sheep on the other pasture land, as already explained. Having now disposed of the land that may not be broken up, as also that which may be profitably converted into tillage, I come to a very large class of land that has been to some extent passed over—*viz.*, the poor heavy clay pasture, down lands, hilly and mountainous tracts of land, and numerous other lands that will suggest itself to your minds that is not first-class for growing corn, and still may be made to produce greatly increased crops of grass by the medium course already alluded to, which is its being simply broken up to tillage for two or three years and relaid to grass. The great drawback to this not being more successfully carried out than it is at present is

hat sufficient attention is not paid to the selection of those grass seeds suitable for the locality, and other circumstances attendant on the case, and also to the fact that grass seed is not put on in sufficient quantity, for we not only want to get a plant for stock, but a very thick one, if you want to get the full benefit the land is capable of producing, and I have never yet seen a fresh land pasture field too thick. Instances have come under my notice of land, laid down to grass in April, cutting more than a ton of hay per acre in September. I also extract the following from a Book on Grasses, by Messrs. Wheeler and Son, of Gloucester as confirmatory of what may be done in this way. "The largest crop of hay that we ever remember to have heard of, was the produce of some seeds supplied by us to Mr. Hurcombe, of Uley. The clover and grass seeds were sown on 6½ acres; it was mown in June, 1865, producing a splendid crop. Immediately after it was made and put in a rich rain came, the aftermath grew most luxuriantly, and in due time was made into hay. The two ricks were sold by auction in March last by Mr. Organ, and were purchased by Messrs. Holmes and Co., of Stroud. Our attention was called to the following paragraph, which appeared in the *Gloucester Journal*, March 10th, 1866: 'The high price of fodder may be estimated by the sale of some clover hay, which took place at the King's Head, Uley, on Thursday last, when the produce of 6½ acres of land was knocked down at the sum of £104. The seed was purchased of Messrs. Wheeler and Son, of Gloucester.' On inquiry of Messrs. Holmes and Co., we received the following reply: 'Gentlemen—In reply to your inquiry respecting clover hay we purchased of Mr. Hurcombe, of Uley, we beg to enclose copy of the weighbridge tickets, by which you will see there was 24 tons 7 cwt. 2 qrs. of first-class hay, in addition to which there was about 7 cwt. of tops and bottoms, which we did not think worth the trouble of weighing.' I give this in full, as it is authenticated, and shows a return of £16 per acre, being nearly 4 tons of hay to the acre. I consider it a mistake to plant the seeds amongst corn if laying down for 4 years or for permanent pasture, for if you get a good crop it kills the young seeds, and if a poor crop it (with the expense) is no better than the extra grass is worth. I would suggest the following: double plough, or breast plough and burn (if the land is very loose and spongy), and then take a crop of oats; then wheat; and next turnips, and after eating off the turnips prepare the ground as for barley, and not put the barley, but seeds, for 3 or 4 years' ley, consisting of—

- 4 lbs. Pacey's perennial.
- 3 lbs. Italian ryegrass.
- 3 lbs. Cocksfoot.
- 2 lbs. Timothy.
- 2 lbs. Meadow fescue.
- 3 lbs. Red clover.
- 3 lbs. Cow grass.
- 3 lbs. White honeysuckle.
- 1 lb. Alsike.
- 4 lbs. Trefoil.

This of the best quality should not cost more than 2s. per acre. These should on no account be grazed the first year, but mown in September, and again early in the following summer, before any seeds are formed in the plant, for as the roots of plants of this class increase in proportion to the top, you get a stronger plant than by grazing and keeping it short; it may then be grazed for two or three years, and then ploughed for wheat; then barley, and cleaned and planted with turnips, and laid again for three or four years; by this means I am sure greatly increased crops may be grown even on the colder heavy land that would not pay in permanent tillage; and on the other hand, as you are aware, the heavier class of soil, if laid to permanent pasture after the first three or four years, produces (even if well manured) a very small return for some years. This is due to the consolidated state the land gets into, and prevents the circulation of the air in the soil: it is especially noticeable in fruit trees, where the land is laid to grass. After the trees are full grown it does not seem to affect them for some few years, and then the trees stop growing, and become covered with moss, and scarcely bear any crops at all. I know of some land that has been laid to grass for 20 years, and is still very poor bad land. If you take a spade and dig up the soil in a field laid for four or five years, and compare this with old turf, it will illustrate what I mean, and it will be found that you can scarcely get the spade into the newly-laid

land, from its firm compact state, and you cannot fail to come to the conclusion that the land in such a state is not fit to grow anything. I am convinced that it is to this cause that the deterioration of newly-laid land proceeds. I have specially noticed a good many fields, when out valuing, and having a spade with me; but as in the course of years the land gradually reverts back to a looser and more healthy state, for the percolation of the air and water, it gradually improves. There is little doubt that it is to this difficulty in relaying land to grass that makes landlords so unwilling to allow old turf to be broken up. The only writer that I have met with upon grass land that bears me out in this view, as to the cause of not getting turf land, is Mr. H. S. Thompson, who in vol. xix., p. 259, of the "Royal Agricultural Society's Journal," says, "All the graminæ that are of value for grazing or mowing, require a fine tilth or mould, as a condition of their successful cultivation. For the first year or two after strong land has been laid down, it retains, to some extent, the porous texture induced by the thorough disintegration which it receives in course of preparation for sowing. The second winter, however, generally obliterates all traces of previous cultivation, and the close and sodden state of the land, which then supervenes, is highly unfavourable to the growth of grass. The land may contain a sufficient supply of all the elements of plant nutrition, but they are in a crude state, and a constant supply of oxygen is required to promote the decomposition of the mineral and vegetable matters, and their recombinations in forms available as plant food; so that if air and water cannot easily and quickly pass through the soil in repeated succession, a check is given to nature's underground cookery as completely as if the flues were stopped in the farmer's own kitchen, and the dinner had to be prepared without any possibility of lighting a fire. Hence, the sudden falling off in the produce of newly-laid grass on strong land, and hence the necessity, at this critical period, for an abundant supply of plant food on the surface to compensate for the falling off below." There is, I think, little doubt, that it is to this cause that the difficulty arises in getting fresh permanent pasture, at all events, whatever the cause of it may be, the fact is patent to everyone, and, therefore, I have every confidence in recommending the medium course under the circumstances I have mentioned. Before concluding my paper, I will refer to one subject that you will, no doubt, have observed that I have scarcely touched upon, and that is, how the land should be treated in breaking up. A few years ago I should have had no hesitation in giving my opinion on the course to be pursued; but having been since engaged in making a detailed valuation of the Clan Union, in Shropshire, consisting of some 85,000 acres, 15,000 to 20,000 acres of which has probably been enclosed within the last 20 years, I had special opportunities of witnessing a great variety of ways in which this land was treated in being broken up to tillage, and when I saw that the owners of, perhaps, three adjoining fields would each adopt a different course, I came to the conclusion that no one system could be much better than another as to be indiscriminately recommended. There are three common modes of treatment, and it must be left to the farmer himself to decide which he considers best for his particular case. 1st. To breast plough and pare and burn. 2nd. To pare and store the turf up in heaps to rot. 3rd. To double plough. Where the land is very spongy, and infested with insects, perhaps the first is preferable, especially if there is any difficulty in getting it firm enough to grow wheat; but as by this means you lose vegetable matters, if you can do without the burning it is better, while if stored in heaps you always have a reserve of manure either for that field or any other; but at the same time there is the expense in both these systems which is considerable. The first seems to be preferable on the oolite and lias formations; on the latter, especially, is burning to be recommended. Mr. Randell, of Chadbury, near Evesham, has done wonders with his arable land by burning it, but on the sandy and lighter soils burning would no doubt be wrong. Whatever system is adopted it will almost always be necessary to lime heavily with fresh quicklime, for old turf appears to get in a kind of acid state, and these acids sometimes require neutralizing before the land will grow corn well. Mustard and rape, seeded on newly broken up land, I have seen recommended, but as I have had no experience in this, perhaps some gentleman who has will give us the result. I will now conclude as I have given you the class of land that ought not to be

broken up, that which may be, and also a medium course, which I believe might be very often profitably adopted on each class of land, and be the means of doubling the increase of food now obtained from much of the inferior pasture even on hill and mountain land, and which I have every confidence in recommending to your notice from what has come immediately under my own observation; and if from our discussion to-night we can show that even one-half the 22,000,000 acres of grass land in Great Britain and Ireland can be improved to the extent of 10s. per acre per annum, we prove that a saving would be effected to the country equal to £5,500,000 every year: and therefore I think our labours will not have been in vain.

Mr. C. S. READ, M.P., said he thought that in treating that subject it was necessary for them as practical farmers to arrive at a principle. They were constantly lectured on their duty to the public. They were constantly told that in these days it was the duty of the farmer to grow more; but he believed that that was a secondary duty, and that the main duty of the farmer was, if possible, to make his farm pay (Hear, hear). He, for one, knew perfectly well that pasture land might be broken up and might produce more meat, and yet what was done might be an utterly losing game. Coming as he did from a district where there was not rain enough to grow roots profitably, and where, therefore, they never attempted to get a large quantity of grass, it might seem presumptuous in him to say a single word on that occasion, but he recollected having in the midland counties broken up grass land at considerable expense. It was an ordinary cow pasture, as ugly and beggarly a piece of land as anybody ever saw, but did somehow or other make a large quantity of butter. They drained it, they subsoiled it, and they spent an immense deal of money upon it for artificial manures and labour, and the result was that, although they were no doubt very good citizens, the pecuniary benefit to themselves was nil (Hear, hear). Therefore, when practical farmers were talking about breaking up pasture lands his advice to them was to look at the expense before they thought of extensively turning up even inferior lands.

Mr. G. SMYTHIES (Marlow Lodge, Leintwardine) said one great benefit of their meeting there was that they heard the opinions of men from different parts of the kingdom (Hear, hear). They had just heard the opinion of a gentleman who came from the east, where the climate was very different from that of the west; and as he (Mr. Smythies) came from the west, perhaps the meeting would bear with him while he said a few words in favour of grass lands. He wished it to be distinctly understood that he came from a district where there was a great deal of rain, and where, therefore, grass might be more valuable than it was in other districts. He did not for a moment pretend to say that what was good for the grass land there would be good for other land; but, speaking of a county where there was a good deal of moisture, he must say he did hesitate before ploughing up a piece of grass land; at all events he should first of all give the grass land in such a district a chance, which he feared had not in all cases been done. He had no wish to find fault with anything in Mr. Cadle's paper, to which he had listened with great pleasure, but he could hardly agree with what was said there about over-draining. Mr. Cadle seemed rather to think that they could over-drain, whereas he (Mr. Smythies) considered it scarcely possible to do so. What he meant was that they could not over-drain, there being a certain amount of moisture which it was impossible to remove from the land. No doubt there were some pastures which were so hard that the air could not readily find its way into them; but if such land was manured and the worms were encouraged to work it, it would so become sited. His own rule was to have grass in every field where he could get water. But he had not left the grass in its original state; he had done a great deal to improve it, and on wet land that was no easy matter. Having tried various kinds of manure he had found that farmyard manure always paid best. Wherever they had light land they could afford to apply farmyard manure for roots and artificial manure for turnips. In the case of heavy land artificial manure did not do so well, and, therefore, it should be used sparingly; but with moderately light lands where they put sheep on the tillage there was no difficulty whatever. His advice was that before breaking up grass lands they should give them a fair chance by manuring them and by eating the roots off them as circumstances might suggest (Hear, hear). Practically on

tillage land they required to sow in March or April with corn crops. There was a difficulty in keeping sheep there, but there was no difficulty in keeping them on grass land, and the land was at the same time very much improved. He did not say anything about grass land in dry climates, having had no experience in the matter. One word with regard to grass land almost forcing farmers to keep stock. If land were all in tillage they could keep stock or not as they pleased; in other words, if a man did not farm well for want either of skill or of capital he might scourge the land and obtain good corn crops, and he thought that was a matter well worthy of the attention of gentlemen who had to do with the preparation of farm agreements.

Mr. H. TRETHEWY (Silsoe, Amphilh) said they had had the experience of a gentleman from the eastern counties, and also that of a gentleman from the western counties, and he cordially endorsed the sentiments which they had expressed. The first thing to be considered in the treatment of land was climate. They knew very well that in the eastern counties, where the climate was so dry, grass land was quite out of the question; they knew very well, too, that in the western counties, where the climate was moist, and where the rainfall was so great, the land was best adapted for the growth of grasses: and he believed that in a moist climate a man could not make a greater mistake than by converting grass land into arable, just as in the eastern counties no one could make a greater mistake than by converting arable land into grass. He had had a great deal to do with the management of land in different counties of England. He knew Gloucestershire, from which Mr. Cadle came, very well; and he knew that a large portion of the land there consisted of grass land of good quality, while some of the grass land was very thin. As he had remarked before, the first thing to be considered was climate; but even in the case of the midland counties, it was in his opinion a great question whether it was desirable to plough up what was called indifferent grass land. It had been the practice for many years in different counties to fold off the grass land for the benefit of the arable land. In fact, he had frequently observed in Leicestershire that farmers sacrificed their arable to their grass land, while in Bedfordshire farmers sacrificed their grass land to their arable. In Leicestershire farmers potted their grasses while in Bedfordshire they folded off sheep on the grass land during the day and kept them on the arable, though the practice had decreased lately during the night. That had been the case for a long time; but both systems were, in his opinion, wrong. The arable land should have a fair chance, and so also should the grass land. In the midland counties there was some of indifferent grass land. Still that district he took to be the medium. The east and the west represented respectively corn and grass, while the midland counties produced both. He thought it was very questionable, taking into consideration the proportions of arable and grass, whether in the majority of cases it could be desirable to break up much grass land. Of course, if there was a very large proportion of grass the case was altogether different. He would now make a few observations in reference to the treatment of grass land. He believed that if grass land were more generously treated than it usually was it would not be found so unremunerative. He could point to several pieces of land which had been drained and manured, and brought into first-class condition; and he could point to other pieces of land, which had been broken up and manured, and been converted into good arable land. But the first thing to be determined was, how far it was desirable to make such changes; and that was a question which must depend upon circumstances. With regard to draining, he rather differed from Mr. Smythies. He (Mr. Trethewy) did not hold with the draining of grass as much as arable land; for this simple reason, that whereas in the case of arable land they wanted to get rid of the moisture in order to secure the ripening of the crop, in the case of grass land they did not want the grasses to ripen, but what they desired was a continual verdure (Hear, hear). He would give an illustration. He would suppose that they had a piece of land which was very wet. For example, he had that very day noticed a good deal of land that was covered with water. Some persons might have said that that land wanted draining, but he would not drain it on any account. On another piece of land he saw carnation or ribbed grasses, and various other indications of moisture. He did not care how soundly that land might ride; he said it was a description of land which required

draining. He would be guided by the herbage which was produced on the land rather than by its actual condition, whatever that might be; and he would not drain the land as much as he would if it were required for arable purposes. With regard to laying down land, he was very much inclined to go with Mr. Cadle. He thought that a great mistake was often made in laying down land for pasture; that was to say, on the after treatment of it. Where land was properly prepared, and a fair amount of seed was sown in the first spring, in his opinion nothing could be more destructive than to graze it with sheep (Hear, hear). The sheep, of course, picked out the young and tender grasses, and nibbled them all up. He held that in the first year such land should always be mown, and he would not have a sheep on it for two or three years. He did not attach as much importance as many people did to the condition the land was in when it was first laid down. Of course, the cleaner it was the better, but he did not care much about it being a little foul (expressions of dissent). That might appear a strong declaration (Hear, hear), but he would tell them the reason why he took that view. He had seen the very best grasses sown, and after they had died away the natural grasses of the country would come up and take their place. He knew a field which had been a piece of wheat stubble, as full of twich as it would hold. Nothing was done to it beyond manuring it, and the result was that the twich gradually died away and the grasses came up, and now that was as fine a piece of pasture as could be seen.

The CHAIRMAN: Where was that?

Mr. TRETHEWY said it was in Cornwall; and he was not afraid to say that the result would be similar in Bedfordshire. The grand thing in the case of grass-land was to put plenty of powder in it, and it would then produce a good herbage.

Mr. COUSSMAKER (Westwood, Guildford) said he wished it to be understood that the observations he had to make, related to poor clay-land. The breaking up of grasses appeared to him a very delicate subject, and he did not think there were many cases in which good tenants, especially if they had a long lease, would desire that to be done. As regarded the finest pastures in the midland counties, would any landlord in his senses consent to their being broken up?

The CHAIRMAN said Mr. Coussmaker must excuse his remarking that Mr. Cadle had not proposed anything of the kind; he did not advocate the breaking up of fattening lands, but only that of the inferior lands (Hear, hear).

Mr. COUSSMAKER, continued: There were various kinds of grass lands. Some were best adapted for the making of cheese or dairy purposes; and he held that these ought to be retained in pasture. Again, some inferior lands were chiefly adapted for the rearing of stock, and if lands of that description were to be broken up, it would be impossible to obtain animals for feeding, as he did not want to see foreigners introducing more of their inferior stock; there had been too much of that already. Having had a good deal of experience in the laying down of grass land, he must say that he doubted very much whether, after the first year or two, it would be found as profitable to break up grass-land and relay it as many persons supposed. If he wished to lay down with corn, of course he would sow it in the spring. He would, however, take very good care to sow his spring corn very thin lest the growth should be too strong; the young grasses only required to be sufficiently protected from the heat of the sun. It was in July that he had been in the habit of sowing his grasses without corn. Taking one year with another, that month was generally showery, and it was a grand point to get the young grasses strong enough to stand against the winter frosts. He agreed with a preceding speaker that they might over-drain grass lands, and supposing the pastures were very wet or aquatic in their nature, the result of over-draining would be that they would die off, and an immediate loss would follow. He did not mean to deny that they might eventually get better grasses, but they would have some years to wait for them. When laying down grasses he had generally got his seeds from Messrs. Sutton of Reading, he describing to them the soil, they sending him the grasses which were most suitable to it. In the first two or three years he obtained abundant crops, but after a time the grasses sown died off, and the natural grasses took their place. As regarded manuring, he had dunged, and dressed with lime, earth, and mixed composts, and so on; but what he liked best was bones, preferring half-inch bones to bone-dust,

because with the former he knew what he was buying. He mixed the bones with earth, and left them till they were almost entirely decomposed, and he applied the bone-dressing to his pastures in the spring. In Cheshire, which was so notorious for its cheese, the application of bones was like drainage, treated as a permanent improvement, and he believed that in many instances the landlord made the outlay and charged interest to the tenant. The question of the breaking up of grass lands on particular farms, or of the proper proportion of arable and pasture, depended, he conceived, on what the farmer wanted to do, as for example, whether he wanted to produce corn or stock, and that system would of course be best for him which he considered was most likely to be profitable.

Mr. J. SMYTH, jun. (Wallington Bury, Baldock) said he perfectly concurred in the opinion that it was possible to over-drain pasture land. He did not agree with Mr. Trethewy that they might lay down arable land in an unclean state and it would afterwards become clean. As a practical farmer he considered it necessary to cleanse the land before laying it down, and they might then expect a good result. He did not think they could smother twich and other weeds in the manner that was suggested.

The CHAIRMAN observed that Mr. Trethewy spoke only of Cornwall.

Mr. SMYTH said whatever might be the case in Cornwall, it would not do in Hertfordshire (Hear, hear).

Mr. NEILD (Worley) thought they were greatly indebted to the gentleman who introduced the subject, especially for drawing the line in that case so carefully and with such judgment that they who ran might understand. He felt that it was generally most undesirable to break up grass land which was paying its way as grass land. He came from the district of Lancashire and Cheshire, and had had a good deal of experience connected with the cattle plague there, and he knew some persons who had had cause to mourn and lament over land which they were compelled to break up because they were afraid to keep cattle, their experience having been worse, perhaps, than that of Mr. Read, in the case of the cow pasture. He could entirely confirm what was said by a previous speaker about the use of bones in Cheshire. Some very stubborn clay lands there had, through the use of bones, produced an abundance of excellent white clover. He (Mr. Neild) did not think any portion of farming required so much attention as the management of grass lands. As regarded the prizes at agricultural shows for roots, they all knew that roots were nursed, and the thing was not in reality what it appeared to the public generally; but he was sure that grass lands required in the present day the special attention of farmers' clubs. They knew very well that grain could be brought from the ends of the earth almost at less cost than a farmer in the midland counties could send it to the London market; and, therefore, it well became them to consider what would pay best. As to the philanthropic view of the matter, and farmers doing this and that for the benefit of the public, they had found the public very grateful to them (laughter); but, nevertheless, they must endeavour to farm each for themselves, as well as for the public (cheers). He was very glad to hear some of the leading farmers taking part in those discussions; but he should be still more glad if the discussion took a rather more practical shape. If he might presume to say so, he would remark that the discussion seemed to have been almost confined to sheep and grain. He knew that those things were essential; but, considering the vast quantities of bacon, cheese, and butter which were brought to this country from abroad, he could not help feeling that the grass-lands had not engaged sufficient attention. He did not think the grass-lands of England produced a quarter of what they ought to produce. He perceived that sewage formed the subject of the next discussion in that Club; and he was glad that that was the case, for sewage had an important bearing on the question now under consideration. The use of the refuse of their great towns was now, as they all knew, one of the great questions of the day; and he hoped they would all go away from this discussion with a desire for the improved cultivation of grass lands. His own experience with regard to the liming of grass-lands was very valuable. Three years ago he put on seventy acres of meadow-land six tons of gas-lime per acre. The corporation of Manchester having a great deal too much of that article, he agreed to remove all that there was; and the result showed that he was right. He had the liming put on the land in a

peculiar way. He did not believe in the necessity of making a compost. He had it all screened through an ordinary gravel screen, and afterwards loaded into one-horse carts, a man standing on the top with his back to the horse spreading the lime broadcast from a spade, the land afterwards being well brush-harrowed. That was done about the month of December, 1867. By the end of February the effect on the field was strikingly manifested, and the result to the hay crop in 1868 was such a swathe of improved sweet herbage as had not probably been obtained for many years before. He made a similar contract last April; but consented to the parties from whom he purchased supplying some of their old customers as well as himself, when, on his sending to remove it, there were five-and-twenty teams waiting in advance of his own, and out of about a thousand tons he only got about 300. The truth was that others had become aware of the benefit to be derived, and knew how useful the article was in grass equally with arable cultivation.

Mr. T. B. DRING (Clarby, Spilsby) observed that the real question was whether it would prove profitable to break up grass land. It was natural for them to wish to do it when the price of wheat was high; but pasture land could not be broken up one day and re-converted into pasture again the next. It would not do to break it up merely because wheat happened to be high, and mutton a low price. They all knew from experience that there were years of prosperity for corn growing, and years of prosperity for producing beef and mutton. The question arose what description of grass land it would ordinarily be found most profitable to convert into arable land; for if grass land were broken up when corn was dear, that might be proved to have been a great mistake when it became cheap. He thought that in the western counties it would in most cases be dangerous to break up grass land; while in some of the counties more especially adapted for the growth of corn, such counties as Lincolnshire and Cambridgeshire, where a large proportion of the farms consisted of grass land, it might be profitable to break some of it. In cases in which land was naturally poor, by growing corn crops and root crops, and consuming the roots on the land, they might be enabled to feed a great deal more stock than they could while retaining such land as pasture, and thus turn it to more profitable account. On the other hand there were some descriptions of land which it would be very wrong to break up. He thought that farmers generally were more ignorant with regard to the improvement of pasture than with regard to that of arable land, especially in districts where "corn" was the farmer's motto. He was of opinion that in the case of some pasture land, if farmers paid more attention to the feeding of stock, fattening them with cake and other substances, they could greatly increase the value of the land, and find pasture more profitable. The description of soil which Mr. Cadle meant was, he believed, heavy clay soil, where it was not practicable to grow and consume root crops on the land. He (Mr. Dring) thought that that was a kind of land which, if it were of tolerably good character, it would be better to keep for grass than to break up. He did not believe in the carting of roots for arable land to any great extent. If they grew roots on arable land and carted them off the result was impoverishment, and there was a great deal of labour and expense. There were one or two remarks of Mr. Cadle that seemed to be a great recommendation of the breaking up of grass lands. He spoke of 6½ acres yielding in the locality to which he alluded 24 tons of clover hay at only two mowings, and of the proceeds amounting to £104. That spoke volumes for the breaking up of poor grass-land. As regards the statement, however, that there was a ton and a half of tops and bottoms in addition, he must say he did not think that showed good management.

Mr. CADLE: There were over seven tons.

Mr. DRING said he admitted that the balance sheet was a good one, but he could not see why the ton and a half of tops and bottoms should not have been made as valuable as the rest, if attention had been paid to the steddle and thatching. Mr. Trethewy recommended that when grass land was laid down with seeds, it should be mown for two or three seasons and not stocked with sheep. He (Mr. Dring) differed from Mr. Trethewy *in toto*. He thought that when land was laid down as a foundation for corn crops it ought to be grazed with sheep.

Mr. TRETHEWY remarked that he spoke of permanent pasture.

Mr. DRING added that in the breaking up of pasture land farmers generally ought to be guided by soil and climate.

Mr. T. CONGREVE (Peter Hall, Brinklow, Coventry) said he was very glad that the discussion had taken the turn that it had, differing as it did from some discussions to which he had listened. They had been told under that roof about the importance of British farmers breaking up every acre of land that they could, inasmuch as every acre kept in permanent grass was farmed at a loss, while every acre of arable land was sure to prove profitable (laughter). As regarded Mr. Cadle's remarks, so far as the good descriptions of grass land in the midland counties were concerned, he (Mr. Congreve) denied that there were many thousands of acres in Northamptonshire, Leicestershire, and other counties which could be profitably converted into arable. It would take a considerable amount of capital to effect such an alteration; and if the views of a well-known member of that Club, and a former alderman of the City of London, were carried out, in the months of June, July, August, and September, London would find itself very short of beef and mutton (A Voice: "We have heard of a bullock and a sheep to the acre"). He had known land that would bear that. Such land as he alluded to could not be stocked with the same amount of capital as arable land. He thought that discussion was likely to do good. His advice to all intending breakers-up was that they should calculate the cost before they did it, have due regard to climate, and see whether they could not keep a greater amount of stock, and by using cake, &c., improve the land. They all knew that with the present price of corn they were farming at a loss. Unfortunately there were seasons when it was impossible to rely on peas and beans. The grass lands were in a better position in some respects than arable lands, and therefore it behoved them to consider well before breaking them up (Hear, hear).

Mr. J. BRADSHAW (Knole, Guildford) said he felt sure that what had fallen from the different speakers that evening would produce a very beneficial effect throughout the country. He was satisfied that the poor pastures of his own county had been neglected. He had been for many years a member of that Club, and until that evening he never heard an opinion expressed there as to the effect of using bones upon land in the south of England (cries of "Oh! oh!"). He knew the effect of bones in Cheshire and Lancashire had been stated. Forty years ago he saw that effect on a neighbouring farm to that with which he was connected, and boiled bones were then applied in the district to which he alluded at the rate of a ton per acre, the cost of bones being at that time £5, while it was now £7 10s. He had imported bones at £3 10s. per ton, and applied them to his land.

Mr. COUSSEMAKER observed that he had applied bones at the rate of half-a-ton per acre, in order to see what the effect would be.

Mr. BRADSHAW added that the effect of applying bones to land was just the opposite of what some persons supposed; the use of them deteriorated the quality of the cheese in Cheshire.

The CHAIRMAN said before he called upon Mr. Cadle to reply he would remark upon the advantages which they as a national club possessed over a mere local one. They had not only "wise men from the east," but they had wise men from the north, the south, and the west (laughter); and if the introducer of a paper failed to recognize the great importance of climate, soil, and other circumstances, they were sure to find gentlemen from other parts of the country ready to put him right and direct attention to those very important considerations (Hear, hear). Mr. Read, with his usual penetration, took a pounds, shillings, and pence view of the subject, and no system that would not bear that economic test was worthy of the consideration of that or of any other club (Hear, hear). Mr. Cadle mentioned in his paper that the breaking up of inferior grass lands led to an increase in the number of labourers, an increase in the beef and mutton to be supplied to the millions of this country; and, therefore he advocated an increase in the growth of roots and grasses, and, indirectly, of animals. He (the Chairman) believed that Mr. Cadle was right, and that it was good policy to break up the inferior grass land of this country; but, on the other hand, he

held that it would be sheer madness to break up the best grass lands (Hear, hear). Corn could, as Mr. Neild reminded them, be imported from the ends of the earth; but the area from which the nation could draw its supplies of beef and mutton was, comparatively speaking, a very limited one. The prevalent opinion in his own county was that with two-thirds or three-fourths of arable land, and one-third or one-fourth of grass, they made a larger return and greater profit than could be obtained when a larger proportion of the land was arable. Mr. Cadle remarked upon the different methods to be pursued in the breaking up of grass-land. He (the chairman) had had some little experience in that matter, and before he determined to break up some inferior grass lands in his possession, he consulted a man who was a great authority in Bedfordshire, and also in other parts of the kingdom, he alluded to Mr. Thomas Bennett, who was for many years agent of the Duke of Bedford. Mr. Bennett said, "If you had a lease for a great number of years, I would not recommend you to pare and burn, because what you would gain in the first three or four years you would lose in succeeding years. Paring and burning," he added, "are simply mechanical operations, and by resorting to them you destroy much fertilizing matter that would otherwise remain in the soil; but," he went on to say, "if I were a tenant from year to year, and had the option of breaking up land, I would pare and burn." He followed Mr. Bennett's advice, and had had no cause to regret it, for he had seen no sensible diminution in the fertility of the fields which had been thus treated. In one field he had tried the storing of turf, and he had seen cause to regret that; injury had been inflicted on the land, which was a strong clay, by carting it off. Nothing, or scarcely anything, grew along the headlands for years, and the labour of taking the turf back to the land was so great that he could not recommend other men to adopt the practice. He believed that the most profitable plan was one not mentioned by Mr. Cadle. A great deal of inferior grass land had been broken up in Bedfordshire during the last 30 or 40 years on the clay lands. The most successful men have been those who made a summer fallow, and followed that with a crop of oats or of wheat. They cropped two or three years in succession with white straw, and, by means of a summer fallow the first year, they got rid of the wire-worm, which was one of the main objects of paring and burning. He quite coincided in the opinion expressed by Mr. Trethewy, as to the policy of keeping sheep off land recently laid down as permanent pasture. He had found the most injurious results to arise from the practice of putting sheep on young seeds of grass which had just been broken up. In such cases the sheep picked out all the finer grasses, and there was no more effectual mode of destroying the prospect of a good turf than stocking newly laid-down grass too soon with sheep. Mr. Neild seemed to have forgotten what the Club had done in years past. So far from its attention having been confined to sheep and grain, those were really exceptions in the list of subjects discussed. In turning casually over the record of the questions considered, he found the following: In April, 1861, there was a discussion on "Sheep and Bullocks as Manufacturers of Manure;" in May of the same year the question, "By what Means can the Feeding of Stock on Pasture Land in Spring, Summer, and Autumn be so increased as to supply the Demand of an Increasing Population?" was introduced by Mr. Owen Wallis; on the 7th of April, 1862, "Dairy Management" was introduced by Mr. Dumbrell; on the following 8th of December the question of "Stock versus Corn" was brought forward by Mr. Robert Smith; in December of the next year Mr. Coleman introduced "The Breeding, Rearing, and Fattening of Stock upon Arable Farms, and the Capability of such Farms to produce Meat;" on the 3rd of April, 1866, Professor Coleman read a paper on "The Management of Grass Land," and in the following December Mr. Duckham one on "The Breeding and Management of Cattle;" in May, 1866, Mr. Robert Smith raised the question of "Increasing the Supply of Animal Food;" on March 2, 1868, Mr. Jackson, of Tattenhall Hall, Chester, introduced the following, "Would not the Making of English Cheese be Generally Improved by the Introduction of Cheese Factories?" and on the 7th of December in the same year Mr. J. K. Fowler, of Aylesbury, read a paper on "The Influence of Railways upon Agriculture." He repeated therefore that sheep and grain seemed almost to have been exceptions, instead of having engaged exclusive attention

(Hear, hear). He must also observe that he was surprised to hear Mr. Bradshaw, who was an old member, say that that was the first time he had ever heard bones recommended in that Club for application to grass land.

Mr. BRADSHAW: I said in the south (Hear, hear).

The CHAIRMAN continued: Since he became a member of that Club he had heard bones recommended about fifty times for almost universal application. Mr. Cadle referred to the important question of the evils which river mills inflicted on a large breadth of land in this country. He thought that in days when steam power was so much cheapened, and when the prices of beef and mutton were so high, it might fairly be said that the time had arrived when the Legislature should deal with that question. Thousands and thousands of acres in this country were water-logged through miserable bits of mills which barely yielded a living to the occupiers, and if he continued of the same mind as he was at present, he would call the attention of the House of Commons to that subject in the approaching session.

Mr. CADLE having briefly replied, on the motion of Mr. Marsh a vote of thanks was accorded to him for his paper.

On the motion of Mr. H. Trethewy, seconded by Mr. T. Horley, junior, a vote of thanks was given to the Chairman, and this terminated the proceedings.

At a meeting of the Committee on Monday, February 7, a Sub-Committee, consisting of the Chairman, Mr. James Howard, M.P., Mr. Cuthbert W. Johnson, and Mr. Sewall Read, M.P., was appointed to look to any Educational measure brought forward by the Government, and to report thereon to the Committee.

The Secretary reported that a complete set of *The Devon Herd Book* had been presented to the Club, by the Editor, Captain Tanner Davy, of Rose Ash, South Molton; and a complete set of *The Sussex Herd Book*, by Mr. Alfred Heasman, of Church Farm, Angmering, one of the Editors; and the thanks of the Committee were ordered to these two gentlemen.

NEW MEMBERS.

Elected January 3.

W. H. Brown, Liddington, Rutland.
J. T. Burnell, Bronsberg Villa, Kilburn.
D. W. Hill, Pinner.
F. J. Sedgwick, Watford.
W. Shaft, Arundel.
J. S. Surridge, Coggeshall.

February 7.

W. Clutton, Penge.
J. W. Ellis, 18, Old Broad Street, E.C.
W. Fairs, Aston, Great Budworth, Northwick.
E. Fox, Jun., Rosemount, Finchley.
A. R. Greenfell, Shalford, Guildford.
H. M. Jenkins, Royal Agricultural Society, Hanover Square.
T. Mace, Shirburn, Northleach.
T. Rigby, Over, Winsford, Cheshire.
M. Roker, Snowdenham, Bramley, Guildford.
J. Scott, Ifley House, Horsey.
J. Taylor, Southill, Biggleswade.
A. Waterer, Nap Hill Nursery, Woking.

THE FISHER HOBBS TESTIMONIAL.—At a meeting of the committee held at the Salisbury Hotel, on Monday, February 7th, Mr. Henry Trethewy, who was in the chair, stated, as surviving executor, that it was Mr. Fisher Hobbs' desire that the testimonial portrait be presented to the Farmers' Club. It was, therefore, resolved that Mr. Knight, E.A., the artist, be directed to deliver the picture at the Salisbury Hotel for that purpose. Mr. Trethewy was appointed treasurer, and the honorary secretaries were requested to pay into his account at Barnett, Hoare, and Co., the balances in their hands respectively. The treasurer was then instructed to pay the balance of £89 5s. due to Mr. Knight. It was determined to hold another meeting to decide as to what should be done with the small balance still remaining, after the payment of his account.

THE NEW FARM.

What glorious, bright, a parking, frosty weather it was! It put everyone in such spirits. The bailiff merry; the labourers pitch with a will, as the empty dung-carts return rapidly over the hard fallow. We are putting a good coating on the autumn-planted potatoes, because what rich soil there was a-top when the stubble was ploughed for planting lies now nine inches deep, and their over-covering mould may be raw and insipid, as it is a field that we have not long had in possession, and the last owner did his farm but niggardly.

The river has sunk so much—probably from the binding-up of the mountain-springs—that I have been able to make a thorough inspection of the effect of the jetties, the strong mid-day sunlight showing minutely not only the material and make-up of the river-bed, but the very notes, too, floating in the air under the wall. I find that gravel has been scooped up somewhere above, and deposited in a fine sloping bed behind each pier, while between them the water rests so still, that, although there is a strong current outside, the dry broken twigs thrown in don't move on in the least. I long for March to come, that we may complete our work by sloping down the steep places of the bank, filling up what holes remain with pared rough turf from a neighbouring meadow, which has been only recently drained, and is covered with a coarse mat of sour tussock grass that no stock will touch. I shall so kill two birds. I shall defend my bank against the river by a tough packing of the hollows, that it will get disheartened in attempting to pick out, and I shall encourage a fresh sweet springing of the pasture. The fine new mould which was filled-in during October the angry flood made short work of when it managed to overleap the jetties. A subsequent inundation, however, was completely baffled by such packing as we did, by way of experiment, of the gaps before emptied. Once get the slope smoothed, and a fair sward upon it, and we shall have no further fear of any wash. We shall only hope that the waters will descend as thick as can be with a loamy solution from the upper country. It is very surprising to see how rapidly grass blades manage to disengage the earthy particles from the turbid sheet as it advances upon the plain. I watched it rush angrily—a very mud soup—up a narrow hollow in the field, where a fence had once stood; but before it had travelled two hundred yards, the element was returning fast to its normal limpid condition, and became clear as crystal when it with difficulty had mounted some higher portion of the meadow.

The purchase of the mare and horse in Wales has made us very forward to our work. It is grand to have had the stubbles all deeply ploughed a month since, so that the rocky soil is getting as friable as can be. For man-gold-wurtzel I shall only work the ground now with a scarifier until it is opened with a double mould-board plough, for the reception of good soapy muck from our deepest foldyard, which is hollowed out of the rock. I saw the juice running out of the carts just now, as mellow and deep-tinted as October ale. We have so much stock in the folds and boxes, that in a month's time it will be full-stuffed again. A couple of acres of cabbage having been planted during my absence in the autumn without the land having, as it should have done, a dressing of manure, the bailiff considering the bed strong enough. I

shall try the effect of sewage, and give each plant a cup of strong drink when the spring comes in, for our liquid-manure tank has long been brimful.

What a pleasant occupation it is getting the lambing-yard ready! We shall this year make it occupy the half of a new stackyard we have established near the bailiff's bedroom window. Having hollowed a long strip about four yards' wide to the depth of 18 inches, and filled the trench with sifted dry wood and coal-ashes, we shall build a roof of straw to it and a back of wattled hurdles, along which, on the inside, deep rain-spouts will be fixed by way of mangers. We so manage to make a great quantity of "artificial" to drill in with the swedes. I have some dozen porkers similarly bedded. The hen and duck houses are all laid with sawdust, with which, too, the fattening cattle are bedded. It does not give half the trouble that straw does in the cleaning out, and goes much further; while we have ample use for the sheaves, there being a good part of them cut-up with hay and pulped swedes; much, too, being strewn under the terribly high-bred pets of the establishment. There is a special virtue in the smell of the pine-wood sawdust: it keeps off insect plagues, I think. Talking of pine-wood reminds one of larch. At one corner of the farm there rises at the base of a sloping arable field a conical hillock rounded on three sides, upon the fourth attaching to and embedded in the field. What it ever can have been quite puzzles us. It might, from its shape, have been a tumulus. The surrounding ground is high, and a hundred feet above the level of a brook, which runs at the bottom a meadow's width below. Rather a distinguished geologist holds that over this elevated table-land (it was not elevated then, but is supposed to owe its rise to volcanic action) once a river ran, disembodying at the point where the conical mound rises, and which, therefore, may be simply an accumulated deposit of drift. Some party, in old time, perchance, had a jetty there. Anyhow, this hillock is so steep that we cannot plough its sides; and to plant it would be to throw an undue shade on the adjacent corn-field. In our despair, certainly, last year we did plant it, and in greater despair the plantation died; so this year, as the steep sides look to the east, south, and west, the frigid north wind being well shielded off by the rising back-ground, so that it is a hot quarter rather than otherwise, I propose to begin at the bottom, and dig or break it up with picks to a considerable depth, after a terrace-fashion (as we see the hill-sides treated along the Rhine). The outside edge of the step shall be higher, or, in other words, the steps shall slope back from the outside edge at an angle of 20 deg. downwards, so that, when rain falls, it shall soak into the sandy rock and soil at the hollows of the staircase, instead of washing off the lips of the steps. Once deeply worked, I expect and hope that we may make a plot, now useless except as a rabbit-lair, of garden-value, for the raising of cabbage-plants, &c. At least, it is worth the experiment; while our occupation will be as interesting as healthful.

Having occasion to open a quarry for the purpose of making the river jetties, I observed, four feet under the surface soil—the hole having been worked into a slope—a regular incrustation of lime, which seemed to have filtered through, and had gathered in cakes about the layers

of stone. There is a certain element of lime in the sandstone itself, which fizzies on the application of spirit of salt, but the stuff which attracted my attention is clearly an infiltrated incrustation from the surface, which I understand was dressed thickly with a compost of earth and lime some fifteen years ago. I know that lime will bury itself in time, but I had no idea that it was so persevering a borer as this.

What an easy thing it is to do good! Would that we were always so inclined! Having been shown by the enterprising agent of some ducal estates in Suffolk a comfortable labourers' reading-room erected at different points of this property, I borrowed the idea, and by the expenditure of a few shillings boarded off half a garden-house, which has temporarily been wainscotted with matting, and is warmed with an old laundry stove. A table is erected at one corner, with a book-shelf above, and a paraffin lamp gives light. When I first broached

the idea all the villagers held off; but any night you may turn in now, between seven and half-past nine, you will find the place crowded. Each subscriber pays a penny a week. The room is managed by a chairman (elected weekly by themselves) and a committee. They are supplied with excellent coffee, at a halfpenny per large cup. The profit on the sale of coffee buys them a weekly paper; beside which, between us neighbours, we put in our own half-dozen various prints every week, and they have a small select library on the shelf. They are allowed to smoke. I am delighted at the success of the plan. Whenever you may turn in you will find a number occupied with the books, and who don't care to talk. I mention these particulars, as it is so cheap a mode of doing positive good. The plan, as I have said, I borrowed from what I saw in Suffolk. My sands are run, and so good-by.

VIGIL.

THE HERDS OF GREAT BRITAIN.

CHAPTER LIX.

MR. LENEY'S.

A trip to Watlingbury before the "South Eastern" Railway came into being, was a weary thing, by comparison. Now you take train at Cannon Street, alip down one side of a Sussex and Kentish triangle, instead of going round two, and reach Tonbridge in an hour. A change at Paddock Wood, and then a few miles down the Maidstone branch, brings you to Watlingbury station, which was in a state of blockade. The hopping season was just over, and a strange motley troop of Celts and Saxons with dishevelled hair, squalling babies, potato-kettles tied up in handkerchiefs, and bunches of faded hop-bines as a token of their autumn outing, struggled up to the barriers, within which the station-master was entrenched. Black eyes were rather the rule, than the exception, with the women, as they fight severely before parting; but the men don't seem "to malice each other" so much. In the midst of an apparently severe tourney we have seen them suddenly relent, perform a sort of wild Pyrrhic dance, and give the kiss of peace.

Mr. Leney, who lives at The Orpines, a pretty spot which Shorthorn men know well, about half a mile from the station, has sometimes a thousand of them at work on his 140 acres of hop yards, which are principally planted with Goldings. The poles are creosoted at the bottom, which generally is in better preservation than the top when their natural term of fourteen or fifteen years is completed. The Goldings, which are grown here and at Yalding, require poles of 16 to 18 feet. The bines just reach the top of the pole, and if they were to lean over much they would lose quality or become "housey," as it is called. The Grapes require an intermediate pole of from 12 to 14 feet; and the Jones's, which don't climb, one of 2 or 3 feet less. These latter do not produce the same quantity, and are grown more in the Weald of Kent and Sussex. The withered bines have their uses, and not only furnish litter and thatch, but serve to put over the mangold "clamp." The whole of the 840 acres which Mr. Leney has in hand are upon the hazel mould, with Kentish ragstone as the subsoil, and 80 acres of it are in permanent grass. Swedes succeed trifolium, and are used with cut straw and malt-dust for cattle in the winter; and the mangolds are Sutton's Globe and

Long Red and Yellow, following rye, which is cut sometimes at a five-foot growth on May 1st.
